Über dieses Buch

Dies ist ein digitales Exemplar eines Buches, das seit Generationen in den Regalen der Bibliotheken aufbewahrt wurde, bevor es von Google im Rahmen eines Projekts, mit dem die Bücher dieser Welt online verfügbar gemacht werden sollen, sorgfältig gescannt wurde.

Das Buch hat das Urheberrecht überdauert und kann nun öffentlich zugänglich gemacht werden. Ein öffentlich zugängliches Buch ist ein Buch, das niemals Urheberrechten unterlag oder bei dem die Schutzfrist des Urheberrechts abgelaufen ist. Ob ein Buch öffentlich zugänglich ist, kann von Land zu Land unterschiedlich sein. Öffentlich zugängliche Bücher sind unser Tor zur Vergangenheit und stellen ein geschichtliches, kulturelles und wissenschaftliches Vermögen dar, das häufig nur schwierig zu entdecken ist.

Gebrauchsspuren, Anmerkungen und andere Randbemerkungen, die im Originalband enthalten sind, finden sich auch in dieser Datei – eine Erinnerung an die lange Reise, die das Buch vom Verleger zu einer Bibliothek und weiter zu Ihnen hinter sich gebracht hat.

Nutzungsrichtlinien

Google ist stolz, mit Bibliotheken in partnerschaftlicher Zusammenarbeit öffentlich zugängliches Material zu digitalisieren und einer breiten Masse zugänglich zu machen. Öffentlich zugängliche Bücher gehören der Öffentlichkeit, und wir sind nur ihre Hüter. Nichtsdestotrotz ist diese Arbeit kostspielig. Um diese Ressource weiterhin zur Verfügung stellen zu können, haben wir Schritte unternommen, um den Missbrauch durch kommerzielle Parteien zu verhindern. Dazu gehören technische Einschränkungen für automatisierte Abfragen.

Wir bitten Sie um Einhaltung folgender Richtlinien:

+ *Nutzung der Dateien zu nichtkommerziellen Zwecken* Wir haben Google Buchsuche für Endanwender konzipiert und möchten, dass Sie diese Dateien nur für persönliche, nichtkommerzielle Zwecke verwenden.
+ *Keine automatisierten Abfragen* Senden Sie keine automatisierten Abfragen irgendwelcher Art an das Google-System. Wenn Sie Recherchen über maschinelle Übersetzung, optische Zeichenerkennung oder andere Bereiche durchführen, in denen der Zugang zu Text in großen Mengen nützlich ist, wenden Sie sich bitte an uns. Wir fördern die Nutzung des öffentlich zugänglichen Materials für diese Zwecke und können Ihnen unter Umständen helfen.
+ *Beibehaltung von Google-Markenelementen* Das "Wasserzeichen" von Google, das Sie in jeder Datei finden, ist wichtig zur Information über dieses Projekt und hilft den Anwendern weiteres Material über Google Buchsuche zu finden. Bitte entfernen Sie das Wasserzeichen nicht.
+ *Bewegen Sie sich innerhalb der Legalität* Unabhängig von Ihrem Verwendungszweck müssen Sie sich Ihrer Verantwortung bewusst sein, sicherzustellen, dass Ihre Nutzung legal ist. Gehen Sie nicht davon aus, dass ein Buch, das nach unserem Dafürhalten für Nutzer in den USA öffentlich zugänglich ist, auch für Nutzer in anderen Ländern öffentlich zugänglich ist. Ob ein Buch noch dem Urheberrecht unterliegt, ist von Land zu Land verschieden. Wir können keine Beratung leisten, ob eine bestimmte Nutzung eines bestimmten Buches gesetzlich zulässig ist. Gehen Sie nicht davon aus, dass das Erscheinen eines Buchs in Google Buchsuche bedeutet, dass es in jeder Form und überall auf der Welt verwendet werden kann. Eine Urheberrechtsverletzung kann schwerwiegende Folgen haben.

Über Google Buchsuche

Das Ziel von Google besteht darin, die weltweiten Informationen zu organisieren und allgemein nutzbar und zugänglich zu machen. Google Buchsuche hilft Lesern dabei, die Bücher dieser Welt zu entdecken, und unterstützt Autoren und Verleger dabei, neue Zielgruppen zu erreichen. Den gesamten Buchtext können Sie im Internet unter `http://books.google.com` durchsuchen.

This is a reproduction of a library book that was digitized by Google as part of an ongoing effort to preserve the information in books and make it universally accessible.

Alliums, some decorative, 162
Allotments: in distressed mining areas, 198; in England and Wales, 338; Richmond, 121
Alpine and shingle plants of New Zealand, 72
Alpine garden, 7, 28, 47, 68, 87, 106, 126, 151, 162, 182, 203, 223, 242, 262. 285, 302, 322, 342, 364, 382, 403, 422, 442, 464, 482, 504
Amaryllis Belladonna var. rosea maxima, 290
American method of rooting cuttings, 154
Amorphophallus Titanum flowering at Kew, 157
Androsace lanuginosa, 262; A. pyrenaica, 7
Anemone narcissiflora, 504
Angelonia grandiflora, 442
Anigozanthos flavida, 182
Annual, a charming dwarf, 190
Annuals: three lovely blue, 136; two new garden, 244
Anoectochili, 26

Answers to Correspondents:—

Ampelopsis and Ivy on a wall, 255; Apple and Pear foliage scorched, 196; Apple foliage: curling, 140; unhealthy, 176, 216; Apples and Pears, stocks for, 216; Apples, failure of, 295; Aphis on Peaches under glass, 196; Aspidistras, cultivation of, 476; Aster stem-rot, 60; **B**ean pods, coloured, 335; Beans, Broad, unhealthy, 120; Bees, Lime trees harmful to, 216; Begonias: and Gloxinias unhealthy, 140; failing, 295; treatment of winter-flowering, 335; unhealthy, 355; Bouvardia Humboldtii, 255; Brassicas: attacked by Cabbage fly, 80; treatment of, for club root, 335; Buddleia alternifolia, 255; **C**alanthes unhealthy, 60; Campanula and Thyme, failing, 140; Carnations infested with red spider, 375; Carrots decaying in store, 355; Cheshunt compound, preparing, 60; Chrysanthemums: 99; diseased, 295; early-flowering, 496; foliage curling, 196; infested with insects, 295; leaf-eelworm of, 355; Club-root, treatment of, Brassicas for, 335; Codiaeum leaves with scale, 335, 355; Copper Beech trunk rugged at base, 196; Crassulas, treatment of, after flowering, 80; Cucumber stems diseased, 40; Cyclamen corms diseased, 415; Cyclamens starved, 120; Cypress shoots unhealthy, 60; **D**ahlias, Single, 315; **E**gg plants, number of fruits on, 19; **F**inger and toe disease, 496; Fruit and vegetable garden, area of, 436; Fruit tree roots diseased, 275; **G**arden: disagreement over letting of a, 216; lease of a, 216; produce, valuation of, 99; Gardeners' notice: on a Sunday, 19; without agreement, 99; Gentiana verna, 436; Gladioli: diseased, 216, 275, 295, 436; not flowering, 415; treatment of, 99; Gloxinias and Tomatos unhealthy, 40; Gooseberry fruits and foliage diseased, 19; Grapes: discoloured, 216, 275; failing, 255, 295; shanked and scalded, 120; shanking, 60, 510; unsatisfactory, 295; Greenhouses, erecting, 335; Grubs in ground, 415; **H**erb in an old garden, 40; Horse Chestnut tree diseased, 196; **I**nsect, large, in greenhouse, 216; Irises diseased, 315; Iris sibirica var. Perry's Blue, diseased, 60; Ivy and Ampelopsis on a wall, 255; **L**awn sand, 196; Lawns, water grass on, 315; Lease of garden, 99; Leucadendron, on growing, 99; Lilium candidum diseased, 60; L. speciosum bulbs after flowering, 315; Lily-of-the-Valley diseased, 335; Lime trees harmful to bees, 216; Lupins dying, 196; Malva flowers lacking colour, 60; Manures, artificial, for a mixed orchard, 476; Melons: cultivation of, 140; failing, 120; unhealthy, 335; Mesembryanthemum, popular pink-flowered, 335; Mushrooms, classification of, 80; **N**ephrolepis, 375; Nymphaea foliage diseased, 216; **O**ak twigs with galls, 275; Onions infested with eelworm, 19; Oxalis lobata, 436; **P**alm foliage with scale, 216; Pansy plants diseased, 60; Peaches: and Nectarines unhealthy, 216; decaying, 255; diseased, 275; leaves mildewed, 196; roots unhealthy, 355; under glass, aphis on, 196; Pear: foliage, scorched, 196; growths diseased 120; Clapp's Favourite, 335; seedling, 335; Peas, culinary, diseased, 99; Planting plan for a border, 375; Plum leaves infested with gall mite, 275; Plums deformed, 255; Poplar, Black, cuttings of, 216; Poplar leaves spotted, 120; Potato scab, 335; Primula japonica and eelworm, 375; **R**adium sand, 140; Rating relief, 375, 436; Red spider, Carnations infested with, 375; Rose bush unhealthy, 315; Rose: leaves attacked by slug worm, 60; Ophelia, failing to open, 99; unhealthy, 99; **S**hrubs: for an eastern exposure, 496; for planting near large Cedar, 396; Stocks for Apples and Pears, 216; Stocks, intermediate, 120; Sweet Peas with streak, 120, 140; Sweet Williams, Violas and, diseased, 476; **T**adpoles in ornamental water, 140; Tennis court, hard, 396; Thuya occidentalis and live stock, 140; Thyme and Campanula failing, 140; Tomato foliage diseased, 196; Tomato fruits: cracking, 40, 216; failing to colour, 80, 140; netted, 275; Tomato plants: failing, 120, 216; and Gloxinia unhealthy, 40, 80; Tulip bulbs with "fire," 99; Turf in bad condition, 176; **V**anilla, on growing, 99; Veronica rupestris v. V. prostrata, 335; Vine foliage: unhealthy, 19; with mildew, 140; scorched, 275, 335; Vine roots unhealthy, 295, 355; Vines: factors governing the development and flowering of, 60; unhealthy, 80, 99, 216, 355; young, 375; Viola leaves unhealthy, 216; Violas: dying off, 216; and Sweet Williams, diseased, 476; **W**allflowers with club root, 335; Walnuts failing, 456; Walnut tree failing to fruit, 196; Water grass on lawns, 315; Weeds on canal banks, 156; Woodlice in Melon and Cucumber houses, 99; **Y**ew and Box hedges in poor soil over chalk, 19

Antwerp International Horticultural Exhibition, 1930, 21, 179
Apple, a gigantic, 338
Apple, from an Australian "pip," 318
Apple James Grieve, 119
Apple tree stem gnawed by mice, 170
Apples and Pears as ornamental trees, 86
Apples: brown rot and, 507; on Metz Paradise stock, 367; the pruning of, 61
Apple trees, the romance of old, 328
Aquatic and waterside plants, colour film of, 102
Aquilegia pyrenaica, 87
Arenaria laricifolia, 106
Aristolochia brasiliensis, 282; A. elegans, 382; A. gigas, 87
Arnold Arboretum: drought in the, 357; Oaks in the, 377; weather in the, 142
Asperula orientalis, 106
Aster alpinus var. Peggy, 126; A. ericoides, 372; A. Skylands Queen, 372
Astilbe simplicifolia var. rosea, 141; 251
Astragalus sinicus, 119
Atraphaxis Muschketowii, 8
Auctioneers and estate agents, 309
Australian fruit trade developments, 458
Autumn in the garden, 384
Azara Gilliesii, 163

B

BAGATELLE PARK, PARIS, 178
Balfour Forest, progress of the, in Palestine, 318
Bamboo, paper from, 217
Barberries, hybrid, at Wisley, 387
Basketry, gardening, 88
Basutoland, natural history of, 399
Bauhinia yunnanensis, 402
Bean harvesting machine, a, 338
Beans, Haricot, 331
Bean, Mr. W. J., 498
Bedford, Mr. Arthur, presentation to, 21
Bee exhibition in Berlin, 198
Bees and fruits, 309, 370, 410, 470
Begonia fields in Belgium, 178
Begonias: basket, 450; and coloured raffia, 430
Belgian florists' annual excursion, 158
Belgian horticulturists, honours for, 478
Belgian market salesmen's reunion, 198
Beliefs, curious old, about medicinal herbs, 166
Berberidopsis corallina, 284, 351
Berberis and Cotoneaster species, a dipterous pest of, 409
Beresford, Mr. J. A., 2
Beschorneria yuccoides, 15
Bews, J. W., M.A., F.L.S. (*The World's Grasses*), 489
Bignonia buccinatoria, 402
Birds, a method of scaring, 103
Birkenhead, jamboree in Arrowe Park, 81
Black Currant bushes: certification of, in Scotland, 197: register of growers of certified, 1929, 319
Black dot disease of Potatos, a further note on the, 493
Bog and water garden, 202, 225, 303
Bol, M. Joseph, 418
Bond, Mr. J., 498

Books, notices of:— A Tentative List of Tulip Names (*Royal Horticultural Society*), 177; A German Cyclopaedia of Hardy Plants (*von H. R. Wehrhahn*), 499; Agricultural Entomology (*D. H. Robinson, B.Sc.*, and *S. G. Jary, B.A.*), 288; American Rock Gardens (*Stephen F. Hamblin*), 29; Annual Report of the Department of Agriculture, Jamaica, 1928, 22; Botanical Magazine, the, 178, 358; British Fern Gazette, The (ed. *F. W. Stansfield*), 82; Bulletin No. 7 (*Iris Society*), 237; Consider the Lilies (*W. E. Marshall*), 188; Daffodil Growing for Pleasure and Profit (*Albert F. Calvert, F.C.S.*), 308; Dahlia Year Book (*W. E. Chittenden*), 22; Field Notes of Rhododendrons and other Plants, collected by Kingdon Ward in 1927-28 (*Lionel de Rothschild*), 121; Fruit Culture (*H. C. Davidson*), 188; Fungi, an Introduction to Mycology (*J. Ramsbottom, O.B.E., M.A.*), 287; Garden Design (*Prosper Péan*), 349; Garden Lilies (*Isabella Preston*), 29; Garden Trees and Shrubs (*Walter P. Wright*), 308: Gardening in southern United States (*H. H. Hume*), 506; Guide to the Flora of the Cape Peninsula (*M. R. Levyns*), 329; Hardy and half-hardy Plants (*A. W. Darnell*), 101, 238, 438; Horticulture, Elementary and Practical (*George W. Hood*), 6; Index Londonensis (Ed. *Dr. O. Stapf*), 297; Journal of the South-eastern Agricultural College, Wye (Ed. *Dr. S. Graham Brade-Birks*), 142; Nature in Wood and Forest (*W. Percival Westell*), 6; Pomologi Beskrivngar över de Viktigaste i sverige odlade Fruktsorterna (*Carl G. Dahl*), 448; Rock Gardens: How to Plan and Plant them (*A. Edwards*), 6; Select List of Roses and Instructions for Pruning (*National Rose Society*), 277, 344; Spanish Gardens (*C. M. Villiers-Stuart*), 384, 450; The Anatomy of Dessert (*Edward A. Bunyard*), 329; The World's Grasses: Their Differentiation, Distribution, Economics and Ecology (*W. J. Bews, M.A., F.L.S.*), 489

Bo Tree, sacred, damaged, 238
Botanical Congress, Fifth International, 497
Bournemouth's exhibition of economic plants, 157
Brade-Birks, Dr. S. Graham (*Journal* of the South-eastern Agricultural College), 142
Branches Park, Newmarket, sale of, 3
Bright, Mr. Frederick, 218
British Empire trade exhibition, Buenos Aires, 1930, 357
British Wood Preserving Association, 459

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 62·6°.

ACTUAL TEMPERATURE—

The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, July 3, 10 a.m. (Greenwich time). Bar. 29·8. Temp. 64°. Weather, fine.

Leaf and Fruit.

IT is a commonplace with gardeners that although fruit is only produced by the manufacturing activities of leaves, yet too many leaves spoil the fruits, even to the extent of checking fruitfulness altogether. To prevent this misfortune, growers have from time to time adopted many and varied devices. When Tomato plants are making too much foliage, a part of each leaf is removed; when Coffee refuses to flower, the branches, so we are informed, are twisted or broken so as to check growth. A nice balance is therefore necessary if leaves are to do their work of supply and fruits are to make full use of the manufacturing activity of the leaves. So far, we are on safe and common ground, but when we seek to advance a little further towards a surer knowledge of fruitfulness and its relation to leafage, we find the way barred by dark ignorance. Why should a vigorous development of leaves prevent or check blossoming? Is it that exuberant leaves supply too much of the good thing which flowers require for their development? Or is it that when leaves grow beyond a reasonable amount they do their work of manufacture less efficiently, and so fail to supply the potential fruit buds with materials without which these buds cannot mature? That some fine chemical distilled by the leaf and required by the blossom will prove to be the *deus ex machina* of fruitfulness, we have no doubt. In the meantime, however, a notable and interesting contribution to this question of leafage versus fruitfulness has been made by Mr. Thomas Swarbrick* in the ninth contribution on the subject of "Factors Governing Fruit Bud Formation." Mr. Swarbrick, who began these investigations in collaboration with Mr. C. E. T. Mann, set himself the task of ascertaining whether fruitfulness and unfruitfulness of Apples are related to any fluctuations in leafage. For this purpose he chose two standard Apple trees of the variety Court Royal, one of which was enjoying an off year in 1925, and the other of which was preparing to bear a full crop in that year. For Mr. Swarbrick recognised that the biennial habit of bearing manifested by so many varieties of Apples might be turned to advantage in his enquiry into leafage and fruitfulness. Accordingly, since "Science is measurement;" the author set himself to count the number and measure the areas of leaves on a given large number of spurs borne on corresponding branches of the "on" and "off" trees. This he did in June in two successive years, viz., 1925 and 1926. The results are of great significance. A tree busily engaged in fruiting behaves as though it were forgetting its other duties. It bears on its spurs only about half as many leaves as it does when blossoming and fruit formation are not engaging its energies. Nor is this the full measure of the neglect with which it treats its foliage department; for during the "on" year the area of such leaves as it does bear is so little as a quarter of that produced during the "off" year when, there being no fruits to preoccupy the energies of the barren tree, it can devote them all to leaf formation. Now Mr. Swarbrick produces evidence which suggests that if the leaf area in the neighbourhood of a spur is too small, that spur does not develop a fruit bud. Whence it seems reasonable to conclude that biennial bearing of Apples is no chance peculiarity, but one which is determined by the poor leaf development which attends full fruitfulness. Owing to deficiency of leafage, fruit buds are not developed and hence the year of plenty is succeeded by a year of scarcity. In that year, however, the tree redresses the balance, makes leaves in plenty; these leaves permit of fruit-bud formation, and so a fat year succeeds the lean one. The moral would seem to be "take care of the leaves and the fruits will take care of themselves." In other words, adopt such means of cultivation and manuring as will encourage the leaves when most they need encouragement. It would seem as though a biennial tree should receive biennial treatment, a liberal supply of nitrogenous fertiliser applied early in the "on" season, when leaf growth is beginning, should stimulate a more vigorous leaf development and perchance secure a sufficient leaf area to ensure the formation of fruit buds. Should this prove to be the case, the biennial habit would be overcome, at least to some extent, and the Apple made to bring forth fruits in due season and no longer to show the caprice of "on" and "off" years.

Our Coloured Supplement Plate.—Miltonias are extremely popular Orchids at present, and the numbers of hybrids or varietal forms of hybrids increase every year. The introduction of such brilliantly-coloured hybrids as M. William Pitt has added interest to the raising and cultivation of these handsome, free-flowering and fairly easily-grown plants, and opened up great possibilities of future colour developments. Miltonia Hyeana commemorates M. Jules Hye, and was the result of crossing M. Bleuana with M. vexillaria, and when M. Hyeana was crossed with M. Bleuana the elegant M. Princess Mary was produced. Several varieties of this hybrid have been exhibited, and one of the best is M. Princess Mary, Westonbirt variety, exhibited by Messrs. H. G. Alexander, Ltd., and portrayed in colour in the Supplement Plate presented with this issue.

Compton Verney.—The late Lord Manton's beautiful and famous estate of Compton Verney, near Kineton, Warwickshire, extending to about 5,000 acres, was sold by auction on June 25 for £79,500, to two purchasers, Mr. T. J. Wilson, of Grosvenor Square, London, and Mr. G. Morgan, of New Lodge, Reigate, Surrey. Compton Verney was bought by the first Lord Manton, then Mr. Joseph Watson, in 1921, from Lord Willoughby de Broke, in whose family it had been since the days of Henry V. The house, which is exceedingly fine, stands in a richly-wooded park containing two sheets of water. The grounds were planned by "Capability Brown," and Compton Verney was among the "show places" of the last century. It is not known what the present owners intend to do with the house and estate, but apparently they do not intend to occupy it personally. Many of the farm tenants were present at the sale, and were naturally anxious to know whether they might expect to retain their security of tenure. They were assured that there was no intention to disturb them.

Tree Surgery in the United States.—During the last half-a-century, a specialised occupation has grown up in the United States in connection with the fast-growing horticultural industry—that of "Tree Surgery." In many parts of the States, new gardens and estates were created—and are still being created—on bare, virgin land, without a vestige of forest, where every tree which is to form the most effective part of the landscape has to be especially planted. Such trees are valuable, and their value increases with their growth; this fact has occasioned the establishment of a number of firms specialising in the care of trees, who visit estates, inspect the trees carefully, advise on their condition, and carry out any remedial treatment that may be necessary. On estates that may possess really old trees, this procedure is doubly necessary, and many ancient Oaks and other forest giants have been saved by the timely filling of holes and other "surgical" treatment. The best of the firms have regular laboratories, presided over by qualified botanists and entomologists, who carry out in a scientific manner every process of pruning, spraying, feeding, etc. The month of June is found to be a good time for overhauling the trees, as sufficient time has then passed since the dormant period for them to show outwardly any signs of ill-health.

Legacies to Gardeners.—The late Miss Maria Margaretta Horrocks, of Ribblesdale Place, Preston, who died on March 25, 1929, left £600 to her gardener, Mr. Thomas Hodson, if still in her service.—The late Sir James Atkinson Hosker, of Christchurch Road, Bournemouth, who died on February 13, 1929, left the income from £1,000 debentures to his gardener, Mr. William Henry Collier and his wife, or from one-half this sum to the survivor.

Strawberry Disease in Scotland.—The alarming reports coming from the southern districts of Scotland concerning the ravages of a mysterious malady which first appeared among Scottish Strawberry crops some few years ago, is naturally causing no little perturbation to growers farther north, and especially in Aberdeenshire, where a large acreage is under Strawberries. Incidentally, it may be noted here that Mr. W. E. Gladstone, the great Victorian statesman, once drew special attention in one of his speeches to the lucrative work Aberdeenshire small farmers and crofters found in the cultivation of the Strawberry, and advised others to follow the example. The speech was not at all to the liking of the regular Aberdeenshire growers, as they feared the incentive to go and do likewise would bring in a host of competitors; and it did so. But the lottery—it can be characterised as nothing else—of Strawberry raising quickly brought its own cure. The novice very soon dropped the enterprise. But to-day many of the most experienced growers are suffering intensely from the ravages of the mysterious malady which is devastating many south of Scotland Strawberry fields. Happily, so far, there is no sign of the trouble in Aberdeenshire, where a big acreage, especially in the Deeside valley, is under this crop. Until the third week in June the crop was doing splendidly, and picking should be in full swing by the end of the second week in July—fully ten days earlier than is usually the experience. The glorious sunshine prevailing of late, so dear to the Strawberry plant, has worked wonders, but a little more rain would be welcomed and be most conducive to the development of the berries.

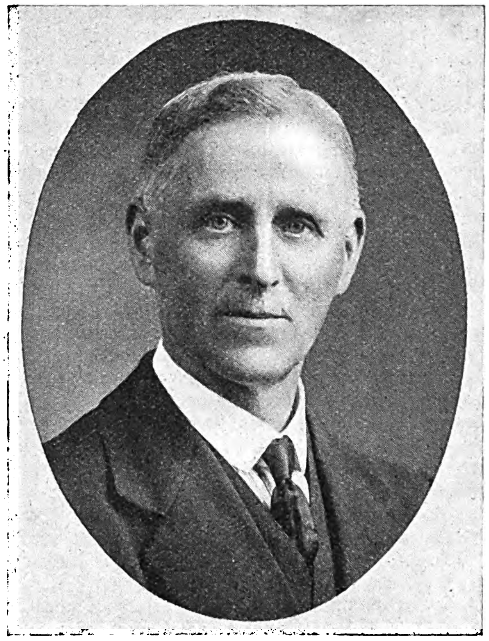
---

* "Some Observations upon the Leaf Area of Spurs in Biennially-bearing Apple Trees." *Annual Report* of the Agricultural and Horticultural Research Station, Long Ashton, Bristol, 1928.

A Garden of Peace.—Mr. H. J. Moore, Toronto, informs us that a great project, viz., that to establish a Garden of Enduring Peace between Canada (and incidentally, Great Britain) and the United States, is to be discussed at the Convention of the National Association of Gardeners of the United States, to be held in Toronto, on August 6, 7, 8 and 9, of this year. Representatives from many horticultural societies and associations will be present and several Canadian and American speakers will give addresses. The project has been approved wherever mentioned and promises of financial support are forthcoming from every quarter. The details of the project, however, are yet to be worked out.

Jealott's Hill.—As agricultural skill is the basis of human prosperity it follows that anything and everything that can be done to increase the skill of the farmer will add to the prosperity of the community, therefore we welcome the addition of Jealott's Hill to the number of research stations where clever scientists and skilled practitioners are combining in efforts to discover ways and means whereby the food supplies of our own land, and other lands, may be increased, in short, intensive cultivation of farms is the aim. Jealott's Hill Research Station is the property of Imperial Chemical Industries, Ltd., but the work accomplished there will be the property of the whole world. The new Station is about six miles from Maidenhead, and consists of about 360 acres of land, up-to-date farm buildings, and finely-equipped laboratories. The whole is under the general direction of Sir Frederick Keeble, to whose foresight and organising ability it is a fine tribute. Under the presidency of Lord Melchett, a distinguished company gathered at Jealott's Hill on Friday, June 28, when Mr. J. H. Thomas, Lord Privy Seal, performed the opening ceremony. Those who accepted invitations included ambassadors from a dozen countries, the Prime Minister of Egypt, the Duke of Montrose, Lord Reading, Lord Birkenhead, Lord Weir, Lord Colwyn, Lord Bledisloe, Sir Henry McGowan, Sir Frederick Keeble, Sir David Milne-Watson, Sir John Russell, Sir David Prain, Sir Daniel Hall, Sir John Farmer, Dr. Bosch, Dr. Hill, Major Chipp and Dr. Darbishire. About seven hundred people, representing science and agriculture in many parts of the world, inspected the premises and the experiment plots, the cattle and the laboratories—the latter are under Mr. H. J. Page, formerly of Wisley—and were entertained to lunch. Lord Melchett expressed the view that the fertilizer industry must be lifted from the realm of faith to the realm of scientific industry, and it was the object of Jealott's Hill to convert faith, through experiment, into profitable practice. Mr. J. H. Thomas followed with a speech that sparkled with humour but kept the practical issues in view. He said he believed in democracy—but an educated democracy; he believed in both capital and labour—but not as opposing forces; brain and brawn must work together for the good of all, therefore he welcomed the advent of Jealott's Hill, with its great financial backing, and its highly trained staff, and felt it a great pleasure as well as a duty to open the station. Lord Birkenhead, Sir David Milne-Watson, Sir Frederick Keeble and Sir Daniel Hall were also speakers at this interesting function. Incidentally, we may add that although Jealott's Hill is an institution devoted primarily to agricultural research, horticulture will not be forgotten, indeed, it is already included, as an experimental orchard is being created, while beauty and fragrance were lent to the ceremony, as the courtyard entrance to the Laboratory building was planted with Heliotropes, and the entrance doors guarded by large blue Hydrangeas.

Mr. J. A. Beresford.—For twenty-five years Mr. J. A. Beresford has been in charge of the gardens of Collar House, Prestbury, Cheshire. His name is a household word among garden lovers for many miles around Manchester, by whom he is regarded as a walking encyclopaedia on all matters relating to flowers and plant life generally. At an early age he entered the gardens of F. R. Curtis, Esq., The Manor House, near Congleton—a delightful residence, afterwards occupied by Sir E. Tootal Broadhurst—and there, under Mr. A. H. Hall (a disciple of that fine old gardener Mr. James McIndoe, V.M.H.) had a thorough grounding in all branches of horticulture, especially the culture of Grapes and Roses. By circumstances of fate, he was, for a short time, left in charge of these gardens while still in his 'teens, and proved himself so capable that he was pressed by his employer to continue in that capacity, even at that youthful age. Mr. Beresford, however, refused the tempting bait, for he realised what a great deal more he had to learn before taking such responsibility on his shoulders. The next few years were spent in hard study and ceaseless work. Everybody said he worked too hard, but he would not believe it, and often, when all his colleagues had finished work, he might have been found in the rock garden or the Orchid house accumulating knowledge that has since been invaluable to him. At the age of twenty-six he became foreman at Collar House, and two years later took over the entire charge, a position he has since held under two families. For nine years, in this capacity, he had as his employer, I. C. Waterhouse, Esq., himself an ardent gardener and keen botanist, and the feeling that existed between them—cultivating plants and studying plant life together—was something more than the touch of nature that engenders kinship. The present owner is R. Moseley, Esq., whose confidence in Mr. Beresford is unbounded, and who fully appreciates the good work done by him, both in the garden and in other directions. The batches of Cyclamens, Carnations, winter-flowering Begonias, Gloxinias, and a host of other things, grown at Collar House, are famed for miles around, as also are the Grapes and, in fact, everything in the garden. As a writer and lecturer on all gardening subjects, no one is more appreciated in the north of England, and those who know Mr. Beresford intimately, appreciate that it is the love of flowers that has kept him so loyal to the gardening profession, for he has repeatedly refused calls to other spheres of labour—the Church, platform, business—but to him gardening is more than a livelihood, or, as he prefers to put it, " man doth not live by bread alone."



MR. J. A. BERESFORD.

A Famous Deeside Rock Garden.—There are many beautiful rock gardens in the north-east of Scotland, but few, if any, can compare with the magnificent rock garden at Glassel House, Aberdeenshire. Situated in the beautiful valley of Royal Deeside, amid enchanting scenery, and famous throughout Britain, this garden is the property of Mr. A. H. E. Wood, who owns Glassel estate. On the kind invitation of Mr. Wood, the city fathers of Aberdeen paid a visit recently to Glassel House, where they were entertained to tea and escorted through the grounds. They found much to admire wherever they went, but the rock garden was a revelation to them. Built on sloping ground of natural rocks, with natural waterfalls charmingly utilised, this garden makes a vivid impression on the onlooker. There are over three hundred different kinds of rock plants, including a superb collection of Meconopses; the lay-out betokens the inspiration of a master hand in the formation of this magnificent ensemble. There was a rumour in Aberdeen some time ago that the Corporation contemplated the construction of a rock garden on a large scale in one of the public parks. If there were any doubts or dubiety in the minds of the authorities, the visit to Glassel House must have completely shattered them. As Councillor Roberts, convener of the links and parks committee, well said, when proposing a warm vote of thanks to Mr. Wood for his great kindness and hospitality, they had spent a perfectly wonderful afternoon. Should Mr. William B. Clark, the worthy Superintendent of Aberdeen's public parks, ever be commissioned to create a rock garden, he will find a wonderful and unique source of inspiration for his task at Glassel House.

Practical and Technical Education for the Glasshouse Industry.—Under the auspices of the Hertfordshire County Council a scheme has been arranged for providing, at the Hertfordshire Institute of Agriculture, Oaklands, St. Albans, practical and technical instruction for the glasshouse industry. It is estimated that there are 3,000 acres of glasshouses in the British Isles, representing a capital investment of fully £10,000,000. Of this area nearly half is concentrated in the Lea Valley, including about 900 acres in Hertfordshire. The industry has displayed great initiative commercially and with regard to marketing and research. The first commercial houses were built about 1880 and the extent of the development is apparent from the area now under glass. For many years grading and packing on approved lines have been practised and now the National Mark has been adopted for Tomatos and Cucumbers. Specialised research was started in 1914 and was originally financed by the growers, but now the Cheshunt Research Station is a recognised research centre doing very important work and receiving Government grants. Recently the Hertfordshire County Council, in co-operation with the Lea Valley Growers' Association, has been responsible for the scheme by which provision is made for instruction and practical training. The Principal of the Hertfordshire Institute of Agriculture is Mr. J. Hunter Smith, B.Sc. A one-year's course of instruction is divided into three terms:—October 7 to December 13, 1929 (ten weeks); January 13 to April 12, 1930 (thirteen weeks); and April 28 to August 2, 1930 (fourteen weeks). Twelve-week courses have also been arranged for those who cannot take the longer course, and these commence on October 28, 1929 and February 17 and July 7, 1930. The charge for residential students residing in Hertfordshire will be £1 15s. per week; for residential students not residing in Hertfordshire, £2 10s. per week. Non-residential Hertfordshire students will pay 10s., and others 20s. per week. Full particulars of this interesting scheme, and prospectuses of the courses, may be had on application to Mr. J. Hunter Smith.

Agricultural Produce (Grading and Marking) Act, 1928.—New regulations in respect of Apples and Pears, in substitution for and revoking the regulations of last year, were made on June 19, 1929. Under the new regulations modifications are made in certain definitions of the size and colour of fruits packed under the National Mark Scheme. Copies of the regulations are obtainable from H.M. Stationery Office, Adastral House, Kingsway, London, W.C. 2, or through any bookseller, price 1d. Packers desirous of being authorised to apply the National Mark to Apples and Pears are urged to apply to the Local Branch of the National Farmers' Union for their county, or to the Secretary, National Farmers' Union, 45, Bedford Square, London, W.C. 1, so soon as possible, in order that the necessary formalities may be completed before the commencement of the packing season.

R.H.S. Gardens Club.—The Annual Outing of the R.H.S. Gardens Club will be held on July 13, when a visit will be paid to the gardens of Ashford, Handcross, by kind permission of Mrs. Lindsay Smith, and later in the day, the garden at Highdown, Goring-on-Sea, will be inspected, by kind permission of F. C. Stern, Esq., C.B.E. The Annual Meeting of the Club will be held at Lloyds Bank Buildings, Worthing, in Mr. J. E. Grant White's office. The party will leave Wisley by motor coach at 8.45 a.m., and will arrive at Handcross at 10 a.m., from whence it will proceed to Worthing, to arrive at 12.30 p.m., when the Annual Meeting will be held. Lunch will be taken at The Arcade Café, at 1 p.m., and at 2.30 p.m. a motor coach will leave for Goring-on-Sea.

Wild Flower Destruction.—Viscount Ullswater, Campsea Ashe, Woodbridge, writes:—"I should be very grateful to any of the readers of your journal, who would communicate to me any instances of the wilful destruction of wild flowers which may have come to their notice."

Imported Potatos Sold as English.—A Liverpool greengrocer was prosecuted by the Ministry of Agriculture recently for contravening the Merchandise Marks Act, 1887, by describing as "English" new Potatos which were shown to be of Spanish origin. These wrongly described Potatos were exposed for sale on May 9, at a time when Potatos from the Scilly Isles were the only British new Potatos on the market, and a purchase was arranged by the National Federation of Retail Fruiterers, Florists and Fishmongers, Limited, who reported the matter to the Ministry. A fine of £10 was imposed, with ten guineas costs.

Dr. M. Golenkin.—Dr. Golenkin, the Director of the Moscow University Botanic Garden, is celebrating this year the fiftieth anniversary of the commencement of his teaching career. Born in St. Petersburg (now Leningrad) in 1864, after a preliminary education in that city he proceeded to the University at Moscow, where, after completing his studies, he remained until 1894, when he went for a year to study in Germany. In 1904 he took his Doctor's degree, and then went to Java for further experience, being appointed, on his return to Moscow, Professor at the University and Director of the Botanic Garden. He has trained many botanists who now hold important positions in various places, and is the author of more than forty works of a literary and scientific nature. He is an enthusiastic teacher, and still lends a willing ear to all on the University staff who seek from him information and assistance in their work.

Sale of Branches Park, Newmarket.—An important country estate, Branches Park, near Newmarket, owned by the late Mr. G. A. Tonge, is to come under the hammer of Messrs. John D. Wood and Co. (Mount Street), at the Mart, on Wednesday next. A feature of Branches Park, which extends to 2,671 acres, is a Rose garden of some three acres. In the beautiful grounds, in addition to the Rose garden, are Paeony and bulb gardens, and a walled garden of three acres. A substantial building near the house forms a heated swimming bath, sixty feet long by 20 feet wide.

Appointments for the Ensuing Week.—Tuesday, July 9: Royal Horticultural Society's Amateurs' Show; Jersey Gardeners' Society's meeting; Royal Agricultural Society's Harrogate Show (four days). Wednesday, July 10: Croydon Horticultural Society's Exhibition; Hereford and West of England Rose Society's Exhibition (two days); Cosham and District Horticultural Society's Exhibition (two days); Reigate Gardeners' Show; Sheffield Chrysanthemum Society's lecture; Guildford Rose Society's Show; West Surrey Horticultural Society's Show. Thursday, July 11: Norfolk and Norwich Horticultural Society's Exhibition (two days); National Sweet Pea Society's Exhibition at Norwich (two days). Friday, July 12: Royal Horticultural and Arboricultural Society of Ireland's meeting. Saturday, July 13: Hull and East Riding Rose Society's Exhibition; Windsor and Eton Rose Society's Exhibition; Leeds Paxton's Society's visit to Harrogate Parks and Knaresborough.

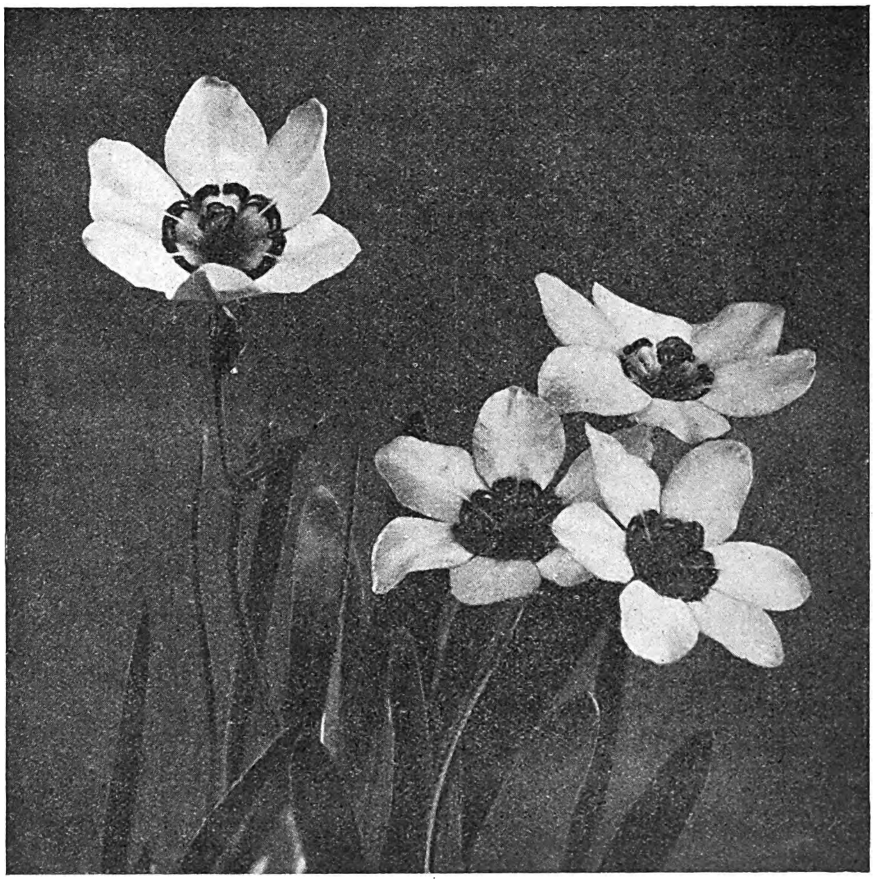


FIG. 1.—STREPTANTHERA CUPREA.

R.H.S. Award of Merit, June 25. Flowers light terra-cotta with purple zone. Shown by Mr. Amos Perry. (see p. 481, Vol. LXXXV).

"Gardeners' Chronicle" Seventy-five Years Ago.—*Inconspicuous Props for Florists' Flowers.*—Pinks, Carnations, and many other things which require to be supported by props, frequently present the appearance, when in beds, of a grove of sticks with plants tied to them, instead of an orderly mass of well-shaped plants, which might be found, on examination, to owe their neatness to props, which without search could hardly have been discovered. The absurdity, where it is avoidable, of having props as conspicuous, or more so, than the plants which they support, is little recognised by gardeners or amateurs, but is constantly pointed at by people of taste, who are not cultivators, and particularly by ladies. Plant growers have a kind of necessary respect for props, from knowledge of their value; but it seems to me this respect for their utility sometimes degenerates into an admiration for their appearance, which leads to their being made much more conspicuous than they ought to be. Be this as it may, it cannot be denied that the true idea of their being helps, which should be kept as much out of sight as possible, is too much overlooked. The best remedy which I have discovered for the evils alluded to, is the use of well-painted straightened wires, of various lengths and thicknesses. For Pinks I have used twenty-four inch lengths of No. 11 wire, which, with two coats of green paint, are almost invisible, and proved perfectly firm and efficient as supports. For Carnations I employed with equal success and satisfaction thirty-six inch lengths of No. 6 wire (about three-sixteenths of an inch thick), but wire of this kind would soon have become loose in the ground, its small diameter presenting little resistance to motion, and to avoid this I employed tapering wooden shods or sockets, about an inch thick at the upper end and seven inches long. These were drilled throughout their length, so as tightly to fit the wires, the ends of which were passed through them, and projected about an inch beyond the small ends, which were thus pointed. The sockets were then dipped in boiling tar, and when this had hardened the wire received two coats of green paint. The firmness and efficiency of these props are most satisfactory, and equally so is their non-appearance. With an annual coat of paint, when out of use, they will last for years and their first cost is trifling. Wires made quite straight by a wire worker, cost me 4d. per lb., which, for small sizes, comes very cheap per 100. The wooden sockets were made for me by a bobbin turner, at 2s. 8d. per gross. When painting the wires I put a spoonful of paint into a woollen cloth laid in the hollow of the left hand, and draw them through it, a plan I find as good, and much more expeditious, than using a brush. This plan of supporting florist flowers was, I believe, first pointed out by Mr. Sivewright, of Cargilfield, near Edinburgh. *W. C. Gard. Chron., July* 8, 1854.

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN MOORE, Manchester.

Disas.—Enquiries are often received with regard to the culture of these cool house, brilliantly coloured South African Orchids, which are not grown in collections so extensively as their merits deserve, possibly owing to the unsatisfactory results obtained in many cases. They are often regarded as very difficult plants to grow, whereas, in reality, their requirements are very simple, once the right position has been found in which they will thrive and give an excellent return of flowers in their season. Disas require a light, cool, airy position where they can be shaded from strong, direct sunshine. They need a uniform temperature in the winter of from 45° to 50°, and the roots should be kept just moist and growing very steadily. A position in an ordinary greenhouse often suits their requirements better than in the cool Orchid house. A well-drained but moisture-retaining rooting medium is required, which, in the growing season should not be allowed to become dry, while the receptacles may be plunged to three-quarters of their depth in Sphagnum-moss to keep the receptacles cool and check evaporation, and so avoid having to water them frequently. Thrips are often troublesome, and if they gain a strong hold on the new growths quickly do irreparable damage, which often proves fatal to the plants. These pests should be kept in check by frequently spraying with a safe solution of an approved insecticide, if the pests have gained a hold; dipping the growths in the insecticide is very effective, provided it is done carefully, and the plants are afterwards tilted to allow the moisture to drain out of the growths. The plants should never be fumigated as this quickly damages the leaves and eventually the stems and tubers. If the division in which the Disas are grown is to be vapourised, the plants should be removed until the fumes have passed away.

Potting.—At this season, Disas are producing flower spikes, and by the time the flowering period is over, new growths will have started from the base, or from these fresh roots will be produced. At this stage, repotting may be done. Use well-drained pots or deep pans, and a rotting medium of equal parts of well-chopped A.1. fibre and Sphagnum-moss, with a little fibrous loam, and charcoal and good sharp sand to keep it porous. Water should be given sparingly until the roots are established in the soil, which should be made moderately firm, but spraying on favourable occasions, especially in warm weather, is beneficial. Formerly only about two species of Disa were cultivated, namely, D. grandiflora and D. racemosa, but now there are good hybrids available, notably, D. Veitchii, D. Luna, D. Blackii and D. Italia. Some of these hybrids are more robust growers than their parents, the size of the spikes and flowers, and also the range of colours, having been increased greatly, although the old D. grandiflora still remains one of the most striking in colour.

HARDY FRUIT GARDEN.

By HENRY H. COOK, Chief Assistant Lecturer, Reading University Horticultural College.

Silver Leaf Disease of Fruit Trees.—As the name implies, the foliage of trees suffering from silver leaf disease develops a silvery or leaden sheen which usually commences in a single branch, but quickly spreads until the whole tree dies from its effects. This disease is so infectious and so disastrous, especially in Plum-growing districts, that in November, 1919, the Board of Agriculture included it in the "Destructive Insects and Pests Act" of 1877 and 1907, "for the purpose of preventing the spread in England and Wales of the pest known as silver leaf, which is so destructive to fruit trees and bushes." The order added further that "The occupier of any premises on which Plum trees are growing shall cut off and destroy by fire on the premises all the dead wood of each Plum tree before April 1 of each year." This date has now been extended to the first week in July of each year. The disease on the tree is not infectious of itself until the fruiting stage has appeared upon portions of dead wood on the branches or elsewhere, but may be carried on the pruning tools from one tree to another. Although no remedy is known, trees which are in the early stages of silver leaf may, if properly treated, be rid of the disease. To affect this, any branches seen to be diseased should be cut back to behind the point of infection at least, and flush with the main stem if necessary, all wounds pared over with a sharp knife, and then covered at once with Stockholm tar. As stated above, the disease is spread by spores of the fungus gaining an entrance to a healthy tree through some wound, hence the importance of protecting cut surfaces. The most suitable time to carry out this operation is now, and any branches so removed should be destroyed, or, at all events, not left in the plantation for the fungus to fructify on them and spread infection among its healthy trees.

Resistency and Susceptibility. — All varieties of Plums are liable to silver leaf disease, although some are more resistant than others. The variety Victoria and Czar are most susceptible, while Rivers' Early Prolific, Yellow Pershore and Purple Pershore and Blaisdon Red are highly resistant to the disease. It has been stated that when Victoria or Czar have been worked on any of these resistant varieties they acquire a measure of resistancy appertaining to that particular stock. For that reason nurserymen throughout the country are using the Yellow Pershore Plum as a stock for the Victoria. This disease is liable to attack all our stone fruits and the Apple, in fact, any member of the Order Rosaceae, as well as trees and shrubs belonging to altogether different Orders.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Vines. — Ripe Grapes in early houses cannot be kept too cool and airy, and unless the foliage is very good, black-fruited varieties will soon lose their colour in the absence of a little light shading. This, however, should not be fixed unless fish nets are used, when one or two thicknesses will soften the sun's rays and also let in light without affecting the health of the foliage. White-fruited varieties, on the other hand, will be improved by exposure to light, when fully developed and fairly coloured, always provided the circulation of air is equal to the expulsion of moisture. After early houses are cleared, the vines require careful management particularly if the weather be hot and dry, and attacks of red spider are likely to occur. This pest soon destroys the best leaves if neglected, hence the importance of syringing freely, and watering and feeding liberally. Laterals are a great help at this season and save the main buds, but should not be allowed to shade the main leaves, or prevent ventilation. In the successional vineries where Grapes are approaching maturity, plenty of air should be admitted with less fire-heat and a gradual reduction in the supply of atmospheric moisture. The roots, however, should not be allowed to become dry, or even partially so, as cutting off the supply too early or too quickly is one of the most common causes of fruit-cracking, especially in such varieties as Madresfield Court. As a rule, one good watering after the berries have commenced changing colour will suffice, provided the borders are covered to prevent the escape of moisture, and the house is kept dry when the weather is unsettled, the laterals being allowed to grow unchecked.

THE FLOWER GARDEN.

By R. FINDLAY, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Shrubs.—This is a good time to make notes on flowering shrubs for future guidance as to their requirements. Many may require more room to show their true characters, and if their future sites can be selected now, and notes made on each, it will be found a decided advantage when planting time arrives. Those shrubs requiring pruning as they pass out of bloom should be attended to so early as possible, so that the production of vigorous young growths is encouraged for next season. A shrub that is flowering with particular freedom at the time of writing, but which does not yet seem to be planted as freely as its merits entitle it to be, is Buddleia alternifolia. This handsome plant flowers on the previous year's wood, and all the flower shoots should be cut back to ensure a supply of young, wand-like flowering growths for next season. This species does not flower freely in its young state, but when once established it is a most desirable and graceful subject, more or less a fountain of flowers in long, arching sprays. It is perfectly hardy; it came through late spring frosts unharmed, while other Buddleias suffered severely. To give a selection of good shrubs is outside the scope of these notes, but attention might, with advantage, be drawn to the numerous new varieties of Philadelphus. A considerable number have been introduced during recent years, and most of them are worth a place where large collections of shrubs are grown. Well-placed and well-grown plants of the old P. coronarius are not to be despised, but how often do we see this, as well as others, struggling for existence in some crowded shrubbery border in deep shade, whereas they should be on the open lawn, where their full beauty and form can be seen and appreciated. The Cytisuses in general are beautiful shrubs, and are well adapted for growing in light, sandy soils. They are difficult to transplant after attaining any size, and should always be grown in pots previous to planting them in their permanent places. Most species come true from seeds, but the hybrids, among which are some very striking sorts, have either to be increased by grafting or by cuttings of half-ripened growths inserted in sandy soil under a bell-glass.

Dahlias.—These are now growing rapidly and require constant attention with regard to thinning the superfluous growths if good blooms are required. See that all the tall-growing varieties have stakes sufficiently strong to support them and that the growths are secured by tying, or irreparable damage will be caused by wind or heavy rain storms.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Salvia splendens and S. leucantha.—Plants of these Salvias, which are being grown on to form large specimen plants for autumn display, should now be ready for placing in their flowering pots. The compost should consist of good loam, spent Mushroom-bed manure and grit, the last to render it porous. After potting, arrange the plants in a cold frame until they have rooted into the new soil, when they may be stood in the open, preferably where they will be shaded from the mid-day sun. Spray the plants with clear water each evening during fine weather to keep red spider in check.

Hydrangeas.—As these plants pass out of flower, and if large specimens are required for next season, they should be partly pruned (*i.e.*, all weak shoots removed) and then repotted into larger receptacles, after which they should be stood in a somewhat shady position out-of-doors until their roots are active again, when they should be transferred to an open, sunny position to secure well-ripened growths. Most cultivators desire to produce some specimens with blue flowers, and this can easily be attained by using from now onwards one of the proprietary preparations offered for this purpose, strict attention being given to the instructions issued with it. Hydrangeas should be propagated so soon as strong shoots are available for cuttings, which may be rooted readily in a close case in an unheated greenhouse. Where space is not limited, the cuttings may be inserted singly in small pots but, on the other hand, three or four may be inserted in large sixty-sized pots and will give good results, so long as they are potted up early. So soon as rooted, the plants may be removed from the case and stood near the roof glass and shaded for a few days from bright sunshine, finally exposing them to full light. After a few days' exposure they may be potted on into large sixty-sized pots, and when they have filled these with roots they may be removed to a cold frame, where they can obtain the maximum amount of sun and air, and may be allowed to remain until it is necessary to house them for the winter. There are several ways of storing Hydrangeas for the winter, but placing them in a cool greenhouse from which frost is just excluded, will give the best results.

THE KITCHEN GARDEN.

By W. G. STAWARD, Gardener to LADY MARGARET RYDER,
Knowle Gardens, Dunster, Somerset.

Celery.—Celery plants for later crops, which were pricked out into frames, should now be ready for planting out. After planting, give the plants a good soaking. The earlier Celery should be carefully earthed up so soon as large enough, and should be given plenty of water while in active growth. Watch carefully for Celery fly or, better still, spray the plants with a strong solution of Quassia extract, or dust them with soot in the early morning to prevent attacks by this pest.

Cauliflower and Cabbage.—Successional batches of these may be planted now to follow those which were planted three or four weeks ago. If plenty of manure is worked into the ground it will prove beneficial in retaining moisture in the soil should the weather remain dry; Cauliflowers especially should never suffer from lack of moisture at the roots.

Dwarf Beans.—A late sowing of dwarf Beans may be made on ground from which early Cabbages have been cleared, to provide a fresh crop during the latter part of the season. Never allow the young plants to suffer through lack of water at the roots, or tough-skinned Beans will result.

Leeks.—The maincrop Leeks will now be ready for planting out into their permanent quarters. The ground for them should be dug well and manured heavily as Leeks are gross feeders. Allow twenty inches between the rows and plant them ten inches apart in furrows six inches deep. So soon as the plants have become established, fill in the furrows while the beds are being hoed.

Marrows.—During dry weather there is nothing more beneficial to these plants than occasional good soakings with water at the roots, applied preferably in the evening. Pinch back a few of the leading growths occasionally, as by so doing the plants may be brought more quickly into a fruiting condition. Remove the fruits so soon as they are of a suitable size for consumption, as they are of much finer flavour when cooked young than when the skin becomes firm.

Asparagus Kale.—For use during the spring months, this Brassica should be planted now, as it is essential that they become firm and of good size before the winter sets in, so as to be able to withstand the rough weather.

Seed Sowing.—The ground from which early Potatos have been cleared should be sown with stump-rooted Carrots, Turnip-rooted Beet and Turnips. So soon as they are large enough to be handled easily thin the seedlings and hoe the ground between the rows frequently.

FOR NORTHERN GARDENERS.

By JOHN HILL, Gardener to ANDREW ARTHUR, Esq.,
Rosemont, Monkton, Ayrshire.

May-flowering and Darwin Tulips.—Where these show signs of deterioration they should be lifted as the foliage commences to die down, spread out in boxes under cover, and allowed to dry off completely. When dried off thoroughly, clean and grade the bulbs so as to have them in readiness for replanting in September.

St. Brigid Anemones.—As these begin to lose their leaves, they should be lifted carefully and dried off under cover. Seed or Potato boxes are quite suitable for drying them in, and they may be piled in tiers and covered with a sheet of corrugated iron to throw off the rain. When dried off, they may be stored in bags or boxes.

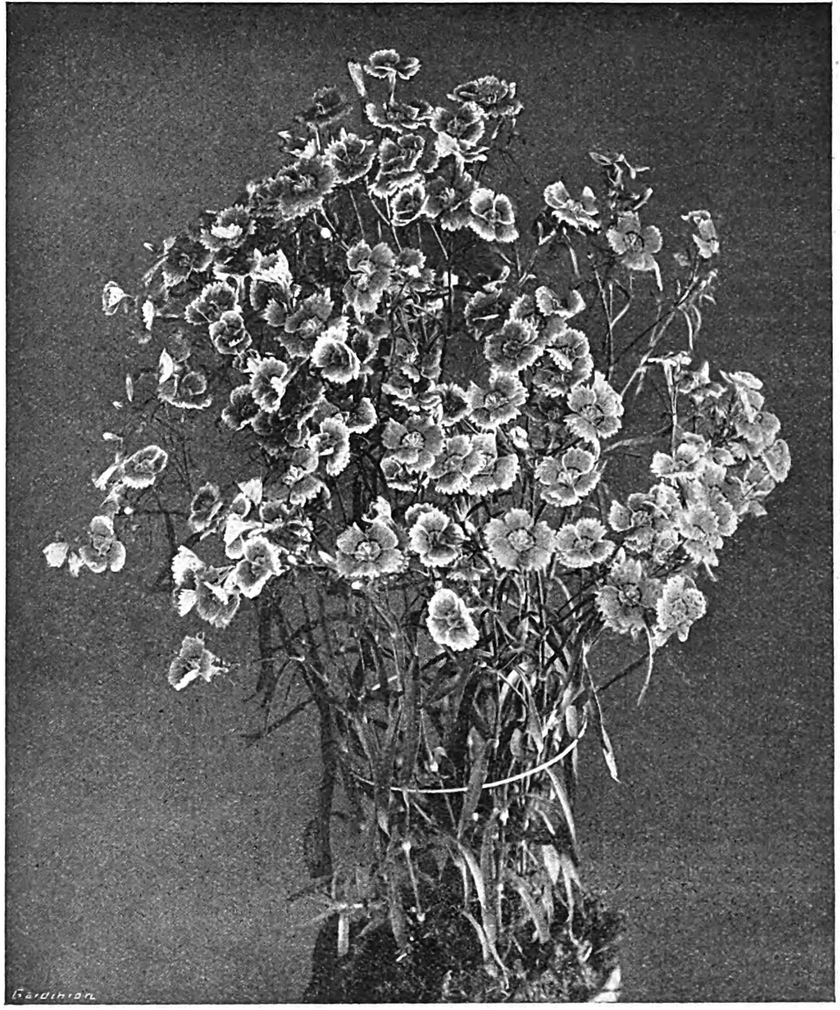

FIG. 2.—DIANTHUS SWEET WIVELSFIELD.

Award of Merit at York Gala, June 18. A hybrid between a Carnation and a Sweet William. It is variable in colour some flowers being light red with paler margins; it will flower within a year of seed sowing. Raised by Messrs. Allwood Bros. and exhibited at the Chelsea and other shows.

Hesperis matronalis var. flore pleno.—Those fortunate in having plants of either the white or purple form of this subject should cut the growths well back so soon as the flowers have faded, and when growth starts at the base the clumps should be broken up and replanted in fresh soil, as this subject dies out quickly if left alone. There are two varieties of each colour type known as French White and French Purple, and Scotch White and Scotch Purple, all of which are most desirable when well grown.

Violets.—These are now making growth and should be given every encouragement to make good crowns; keep the ground clear of weeds and hoe between the plants frequently.

Remove all runners or suckers, preferably by pulling them off, the object being to develop the central crown. If red spider appears, spray the plants at once with an approved insecticide, and, if convenient, give the plants heavy soakings with water, and in hot weather, spray the foliage occasionally.

Late Peas.—Thin these where germination has been good, so that the plants have room to develop properly; cultivate the ground well between the rows and stake the plants at once.

Vegetables.—Broad Beans should be earthed up and staked securely in good time; as they attain a reasonable height, pinch out the tops; this serves the double purpose of assisting the development of the pods and preventing attacks of black-fly, which usually infest the growing point. All vegetable beds should be hoed frequently or cultivated in dry weather, with a view to reducing the necessity of watering, which should only be done if copious supplies of water are available. Driblets are worse than useless, and it is far better to rely on mulching or surface cultivation to conserve moisture.

Strawberries.—If plants are required for producing early crops, the first runners should be secured and laid in, either in pots or in a specially prepared piece of ground between the rows. Three-inch or four-inch pots should be filled with good turf and animal manure, and the runners pegged down into them. If the pots are half sunk into the ground, less trouble will be experienced in watering and keeping them upright; all succeeding runners should be removed.

NOTICES OF BOOKS.

Rock Gardens.

THE immediate impression thrust upon the reader as he opens this book* is that its author has attempted the impossible. To cover the whole theory and practice of rock, water, bog and wall gardening within the limits of 312 pages, nearly fifty of which are occupied by illustrations, and at the same time to profess to give a description of "each individual plant," with propagation and cultural details, is a task that would blunt the courage of most. But the author claims to have achieved not only all that, but to have dealt with the construction and management of Lily ponds, the alpine house, the moraine and paved gardens, and with the culture of their respective occupants. Further, at the expense of more legitimate claimants for space, he does not hesitate to include many genera of shrubs and forest trees, Ferns, Grasses (including Bamboos), spring and half-hardy bulbs, Rhododendrons, Liliums, the culture of Roses and even annuals. The result of this effort to contract into one volume matter that, to do it justice, could not be squeezed into half-a-dozen works of equal size, is obvious. The information, much of which is sound enough, so far as it goes, is too sketchy to be helpful to those who might take up the book as a reference, and the generalisations which sweep through its pages are apt to lead astray the novice who looks to the author for guidance. Then there is such an interminable number of lists and tables of plants for various sites, soils, etc., that the overlapping and repetition which naturally ensues leads to confusion.

Since Mr. Edwards has an easy style and shows no little ability in the handling of his material, the above seems the more regrettable. The discerning reader will gather much that is of value from his pages, especially hints on planting, seed-raising and other technical points. But not many will agree with the author when he states that crazy-paving is "the most satisfactory type of path for the rock-garden." Nor will the experienced builder of a dry wall who believes that stone must rest on stone, countenance the author's advice to leave an earth space of from one to three inches between each block, *i.e.*, laterally. Slips in spelling are few, but Mr. Edwards has not been so careful in other respects. Anagallis tenella, for example, is given as a half-hardy annual, Borago laxiflora and Omphalodes cappadocica as annuals. We are told to plant Erythroniums only one-and-a-half-inch to two inches deep, and Linaria vulgaris is given a description which fits a very different plant, L. Cymbalaria. Bryanthus erectus is stated to be a good species, and this shrub is robbed of another distinguishing feature by the statement that it has "pitcher-shaped flowers." Then the author gets badly boggled over the genus Phyllodoce (Bryanthus) by calling it Phyllothamnus, which is, of course, the proper generic name of what he calls Bryanthus erectus. Cistus and Helianthemum are only a little less mixed-up. Calluna vulgaris var. alba Serlei is stated to have double flowers and to grow but twelve inches tall. Veronica Balfouriana, a shrub of three feet, is described as a herbaceous species of three inches, and in far too many instances is the word "species" used when it should be "variety," and *vice versa*.

If such obvious slackness is irritating to even a moderately well-informed reader, it is likely to be the reverse of instructive to the seeker after accurate information. Further, a great bulk of what might have been useful matter is discounted by the fact that the author's advice, as on the selection of plants for certain positions and seasons, is so often at variance with practical experience. We are, for instance, asked to include Aubrietias, Waldsteinia trifolia and Asperula odorata among the best moraine plants, while many really suitable and choicer subjects are omitted. Would anyone not looking for trouble plant Petasites fragrans (described as having "white flowers"), Vinca major, Epilobium angustifolium, Berberis stenophylla or Abies nobilis in the bog garden? Yet, these are recommended, and several excellent and well-known plants not even mentioned. Again, where one would expect a selection of rock garden Berberises, only two inferior dwarf varieties are given, and they are classed as species. In Potentillas, Pentstemons and many other important genera, some of the finest rock garden plants are ignored. Saxifraga umbrosa is recommended for the bog, and such superb bog plants as Primula Florindae and P. helodoxa are not so much as named. Iberis sempervirens is recommended as a suitable subject for the alpine house, Daphne Cneorum and Dryas octopetala for places in full shade. As for dwarf Rhododendrons, the meagre notice accorded these in what purports to be a modern book on rock gardening is incomprehensible.

The publishers are to be commended for their part in this production, and if many of the coloured plates are not particularly attractive, the fifty photographs are mainly good, so good in some instances that they make one wish they had a more deserving backing in the text. The next time Mr. Edwards sets out on a venture of this kind he must begin by readjusting the focus of his ambition. Having done this, let me implore him to treat his subjects with that nice individual intimacy with which he advises us to approach the slug. "When found," he tells us, we are to drop a pinch of salt on the head and another pinch on the creature's back (the tail he omits). But then, pinches of salt are nasty things to meddle with in a garden, and as liable to get into wrong places as they are on a writer's table. *J.*

Horticulture, Elementary and Practical.*

THE author of this book was formerly Associate Professor of Horticulture in several of the American universities, so that his experience is that of the United States. One of the first things that will strike the reader is the distance allowed between rows of Carrots, Onions, Parsley, Radishes, etc., in a commercial garden, as compared with the rule in this country, and that would seem to be to enable horse cultivation to be employed. In suburban gardens the distance is seldom less; but for hand culture in city gardens the distances approach more nearly those allowed in English market gardens and others generally. In Fig. 5, Asparagus, Gooseberries, herbs and Radishes are all shown to be planted in rows three feet apart. The pruning knife would have to be used freely to keep Gooseberries in this space, unless the bushes are of more limited growth than in this country. Doubtless the Radishes are intended to be sown in the form of a long, narrow bed. All sowings are formal, going in lines the whole width of the garden, sometimes the whole length. This certainly facilitates cultivation; and the author certainly insists upon orderliness. All perennial crops must be kept together, and annual ones by themselves, so that the proper cultivation at the proper time can be given.

It is interesting to note in a chapter on the seed and its needs, that Leguminous seeds not infrequently absorb their own weight of water, and the seeds of some Clovers absorb more than their own weight. Doubtless this is the reason why Peas and Beans rot in the soil if sown when the latter is too wet. Seeds of various kinds can have too much moisture at the initial stages of germination, and the author gives good advice on this point. All seeds have their own minimum, optimum and maximum at which they can germinate, and it is here stated that Rye will germinate on cakes of ice. It has been recorded in this country that the Sycamore will germinate at 32°F. It would seem that large growers in America have to depend on the testing of seeds for themselves, as to their germinating capabilities, and they are advised to do so. Methods of testing seeds are much the same as here, even if the apparatus varies in some respects.

It may make readers take notice when the author writes of freezing the soil to destroy organisms in it when getting it ready for a seed-bed, or for filling seed-boxes. He also recommends autumn ploughing to destroy nematode worms that ruin Strawberries, and the growing of other crops for two or three years to exterminate the pests. The sowing of a lawn by means of a "seeder" shows how every operation comes to be mechanised until the modern sower has lost the skill of his predecessor. In transplanting various subjects to the open ground, he calls attention to the fact that many roots are broken away, and recommends the removal of twenty-five to fifty per cent. of the leaves to balance the roots and foliage. That may be necessary in the warm and arid climate of America, but it is unnecessary in Britain.

The book runs to 382 pages, including a good index, and much information is embraced between the covers. The contents include twenty chapters, dealing with propagation, budding and grafting, pests of cultivated plants, spray machinery and spray materials, the pruning of plants, harvesting and marketing, winter protection of plants, the Strawberry, bush fruits, the Brambles, the Grape, home-fruits, stone fruits, Citrus fruits, beautifying the home garden, and the water garden. The illustrations are mostly reproductions from photographs, and represent tools, implements, methods of budding and grafting, packing for market, etc. The Gooseberries shown grow remarkably erect compared with ours; suckers are allowed, but thinned in pruning. Printing, paper and editing leave nothing to be desired, and much information of a useful kind may be gleaned from the pages. Being of the nature of a class book, it has review questions at the end of each chapter.

Nature in Wood and Forest.*

THIS is the third book in "The All-round Nature Books" series by the same author. Its contents are contained in seven chapters, with twenty-three very good line drawings of plants, mammals, birds and insects that inhabit woods and forests.

Only the larger trees are discussed, as being proper to the situation, although some passing allusion might have been made to the early summer beauty of such small trees as the Hawthorn, White Beam and Laburnum on the margins of woodland. The last-named are, of course, not British. Round about Christmas, or in the darkest period of the year, according to the author, the ancient Britons or Celts carried on the same, or similar, forms of amusement under the Mistleto as are practised in these times. He recalls the time when the Weald of Kent, Surrey and Sussex was one vast forest. One can imagine something of it when it is noted that many of the existing places have the word "hurst" attached to them, indicating the time when the forest got broken up into detached woods. The reader will note, in connection with the Rowan and other well-known trees, that none of the old superstitions attached to them is revived. Belief in them has almost died out, although some others (here unrecorded) would seem to have arisen recently, as if superstition were part of the human psychology.

In dealing with the larger wild flowers, the author states that the Willow Herb has the habit of suddenly springing up in clearings. It was there all the time in the wood, carrying on a precarious existence by means of its underground stolons, until stirred into activity by the advent of sunshine. He states it is often grown in gardens, but that is the short-podded Continental form, which is the one he illustrates. Foxglove is a corruption of Folk's or Fairies' Glove. He describes the Barberry as evergreen, but that is wrong, unless he refers to Berberis aquifolium, which is often planted for covert. Among the smaller wild flowers, he noted one mild winter on December 28, that many plants of the male Dog's Mercury were in bloom, but he failed to discover any pistillate flowers and asks his readers for notes concerning the phenomenon. The answer is easy. In dioecious plants one often finds the sexes widely separated, as in the case of the Field Thistle, Poplars and arboreal Willows.

---

* *Rock Gardens: how to Plan and Plant Them*, by A. Edwards. Ward, Lock and Co., Ltd., London. Price 7s. 6d.

* *Horticulture, Elementary and Practical.* Prepared especially for those interested either in Home or Commercial Horticulture. By George W. Hood, M.Sc. Third Edition, thoroughly revised. Illustrated with 156 engravings. London: Henry Kempton, 263, High Holborn, W.C. 1929. Price 15s. net.

* *Nature in Wood and Forest*, by W. Percival Westell, F.L.S., F.S.A.Scot. Illustrated. London: The Sheldon Press, Northumberland Avenue, W.C.2. 1929. Price 2s. 6d.

In the chapter on mammals, the wild animals and their doings are discussed, from the badger, otter and fox, to the long-tailed wood mouse; but the wild fauna has been greatly reduced since the time when Londoners hunted the wild bull and the boar on the slopes of "Happy Hampstead." Among the larger birds, the author states that the jay is one of the most handsome birds in Britain, but a vagabond, and that a pair would do more harm in egg-stealing than all the boys of a parish. He was so pleased with eight jays in his garden that he suffered them to dig up and eat all the Peas he had sown. He repeats the story that the cuckoo lays her egg on the ground, picks it up in her beak, and lays it in the nest of some other bird, including the moorhen. Apparently he takes no notice of Mr. P. Bunyard's findings that she swallows the egg, carries it to the nest and regurgitates it.

All the chapters are interesting, particularly those relating to the larger and smaller birds. The book makes light and entertaining reading for young naturalists in various fields of science, as well as the general reader, and it is well edited.

ALPINE GARDEN.

ANDROSACE PYRENAICA.

THE Androsaces comprise a group of plants of great beauty, belonging to the Primrose family, and varied both in form and habit. The downy-leaved forms are difficult plants to cultivate successfully near large cities where dust and soot gather on the leaves.

The illustration (Fig. 3) depicts a pan of the charming A. pyrenaica, a most distinct plant, forming dense cushions of small, greyish rosettes which are covered with small, star-shaped, white flowers; even when out of bloom the neat cushions are most attractive in the alpine house.

The dwarf, mossy Androsaces are rather difficult to grow in the open and are only a success in the more northern districts, where they should be planted in the fissures of rocks in a mixture of peat and sandy loam. Even then great care is required to guard these tiny plants against slugs and aphis. Where frames or an alpine house are available, such Androsaces as A. pyrenaica, A. helvetica and others belonging to the "mossy" section, are delightful subjects for growing in small pots or pans.

Such well-known kinds as A. lanuginosa and A. sarmentosa will grow freely in any good, well-drained garden soil on the rock garden. The former, a native of the Himalayas, is a precious rock plant, its prostrate shoots trailing a considerable distance and bearing rosy-lilac flower heads in great freedom during late summer, at a season when flowers on the rock garden are none too plentiful. It is perfectly hardy, but like all downy-leaved plants, it is not happy near large cities where the atmosphere is less pure than in the open country. A. sarmentosa and its various varieties are too well-known to need description. They will grow freely in a warm, well-drained loam, producing their soft pink-coloured flowers on every rosette. The varieties known as A. s. var. Watkinsii, and A. s. var. Chumbyi, are neat and free-growing plants worthy of being included in every collection. *F. W. G.*

SISYMBRIUM PINNATIFIDUM.

SINGULARLY rare, in nature as in gardens is this handsome Crucifer (syn. Hugueninia tanacetifolia). It occurs east of the Valis, and on Mount Cenis is fairly abundant, filling many of the curious gypsum pockets with golden beauty. It is no plant for a choice position, but in a quiet corner, in half shade, perhaps, and rather moist soil, will prove as effective as any Alyssum during May and June. I have written "half-shade," but here, in the nursery, the stock-plants, which are planted out in nursery rows, in a fully exposed position, are perfectly happy; they have fairly rich, well-drained soil, and this seems to be the first need of the plant.

Seeds germinate readily and are freely produced, and in two years will provide noble masses of Tansy-like foliage, very handsome in itself, and covered in due season with multitudes of the tiny Cruciferous flowers, so small in their individual selves, but forming a grand show in their generous quantities. The colour is good, a yellow, not giving any suspicion of green, as so many yellows do, but a soft, clear colour, effective, and lovely for association with other, brighter colours.

This plant should certainly be better-known; at present it is only the botanists who recognise it when they see it, and always observe, "Why ever is that lovely plant not more grown?" *Will Ingwersen, The Birch, Sharpthorne, Sussex.*

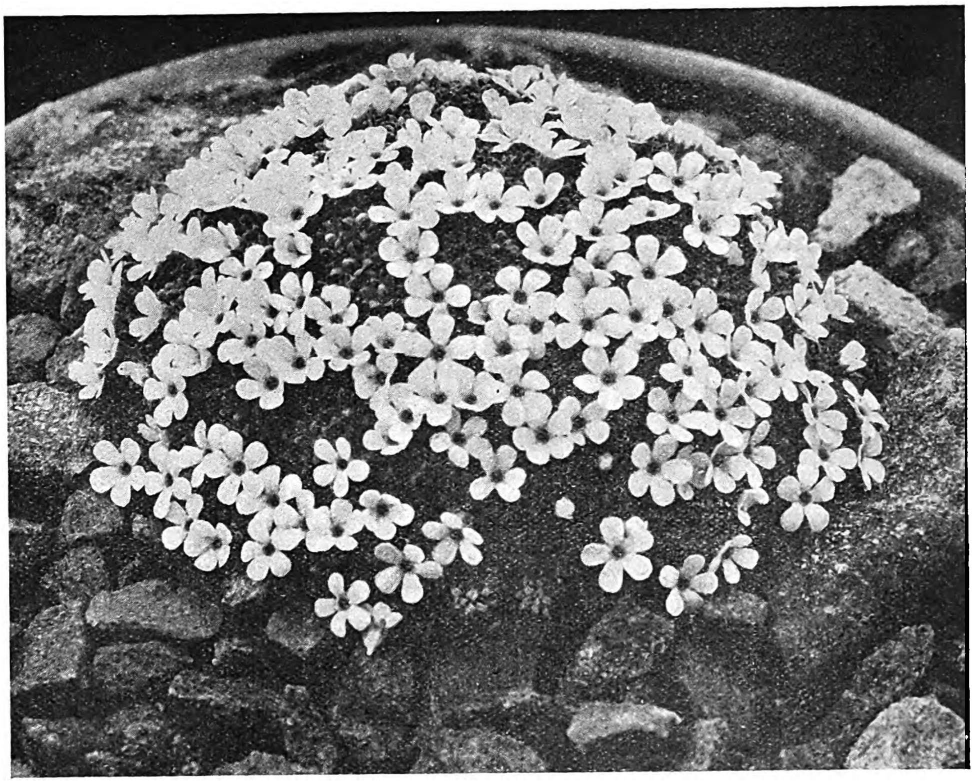

FIG. 3.—ANDROSACE PYRENAICA.

GENISTA LYDIA.

THIS dwarf Broom, generally known in gardens as G. spathulata, has been occupying a spot on the top of a dry retaining wall for some years, and every season in early June it is a glowing mass of rich golden-yellow. If it is a form of G. tinctoria, as some authorities believe, it is certainly the finest representative of that species, regarded as a dwarf flowering shrub. In habit of growth and in its sparse, slender branches, which are almost prostrate, but arching, with their tips depressed, G. lydia suggests an Ephedra. The simple, very narrow, deciduous leaves are few, and at any season other than the present the little shrub can claim no pretensions to good looks. But towards the later spring the spreading and rather fish-bone branches bristle with innumerable short growths which in a few weeks develop into a blaze of blossom.

This delightful little Broom is perfectly hardy and an excellent subject for a hot, dry place among rocks, over which it can display its copious showers of bloom. It appears to be a native of the Transylvania region and other parts of eastern Europe. One or two botanists also consider it synonymus with G. caespitosa and G. leptophylla. It has never borne seeds with me. *A. T. J.*

INDOOR PLANTS.

IXORA MACROTHYRSA.

THIS, perhaps the finest of all the Ixoras, is now seldom grown, chiefly because considerable warmth is necessary to produce perfect plants. I well remember the small stove house in Messrs. Cypher's nursery at Cheltenham, which, in pre-war days, was reserved for the culture of this magnificent species, and the specimens exhibited by this firm are too well remembered to need comment from me.

Perhaps more familiar under the name of I. Duffii, I. macrothyrsa was introduced from the South Sea Islands in 1878; the flowers, borne in immense heads, are deep red, suffused with crimson as they age. The large leaves will often attain ten to twelve inches in length, and are a deep, glossy green.

All Ixoras are naturally free-flowering, and even small examples of this noble species, each carrying one big head of bloom, are highly decorative; specimen plants may be grown to large dimensions.

A rooting medium of fibrous and sandy peat, plenty of heat and moisture, even more than is required by most Ixoras, and a light structure, are essential to the successful culture of this otherwise easily-grown and magnificent species. Cuttings afford a ready means of increase. *Ralph E. Arnold.*

PERISTROPHE SPECIOSA.

THIS charming flowering plant is a native of India. Its generic name refers to the corolla, the tube of which is twisted so that the flower itself is actually upside down. As the specific name implies, the plant is extremely showy. It is a member of the Natural Order Acanthaceae, and is often referred to as Justicia speciosa.

The flowers are rich carmine-purple in colour, and are very attractive, peeping out, as they do, from among the ash-grey-coloured foliage.

Peristrophe speciosa is a useful little plant for growing in the conservatory or stove, as it comes into flower in early November, and is of easy culture.

Cuttings may be secured in the spring and rooted in a close, warm propagating case. When well rooted, they should be placed singly in sixty-sized pots and grown on in a moderately warm house; during the summer the plants may even be grown in a cold frame, but they require to be flowered in a house. The compost should consist of equal parts of good, mellow loam and leaf soil, with a fair amount of sand added to keep it open. Five-inch pots will be large enough to flower them in. Pinching the growths should be attended to regularly so as to secure compact, bushy specimens that will give an abundance of flowers. *F. H. Wright, University Botanic Garden, Cambridge.*

BUDDLEIA FARQUHARII.

THIS hybrid between B. asiatica and B. officinalis was raised by Messrs. R. and C. Farquhar and Co., of Boston, Massachusetts, in 1913. It is an excellent plant for winter-flowering in the greenhouse, and is fairly commonly grown here in the United States, although I have no recollection of seeing or hearing of it in England. The foliage is practically identical with that of B. asiatica, but the fragrant flowers, instead of being white, are pale mauve in colour, and the spikes of bloom are much looser and broader than those of B. asiatica. These spikes are produced very profusely and are arranged in large, terminal panicles.

Buddleia Farquharii is a worthy companion of the better-known B. asiatica and flowers about the same time—that is, in January and February. It is propagated readily from cuttings of non-flowering growths taken from cut-back stock plants from April until June. The young plants should be potted on as growth demands, finally placing them in eight- or nine-inch pots. During the summer the pots may be plunged out-of-doors, but constant attention should be paid to watering. Syringing will prevent attacks of red spider, which may prove troublesome, and feeding is beneficial when the final pots are filled with roots. Before frosts are liable to occur, remove the plants to a greenhouse with a night temperature of 40° or 50°. *T. H. Everett, New York.*

HARDY FLOWER BORDER.

POLEMONIUM CARNEUM.

THIS is a very attractive plant and easily grown. The leaves are thinner and of a darker green than those of P. coeruleum, and they are also narrower and more pointed. The flowers open pale buff, but gradually darken to a delicate pink, which becomes somewhat purplish. They are more loosely arranged than those of P. coeruleum, but are of about the same size, and the plant attains a height of about one foot.

P. carneum is a native of north-west America, and my specimens came from a contributor to this journal. Ordinary soil suits this species. *C. Nicholson.*

ERIGERON AURANTIACUS.

AT a glance, Erigeron aurantiacus might easily be mistaken for a Hieracium, for, unlike the majority of the species belonging to this extensive genus, and which have flowers of varying shades of white, lavender and mauve, this species, which hails from Turkestan, has rich, semi-double, vivid orange-coloured flowers, which are very striking.

E. aurantiacus may be grown in the herbaceous border, where it should be planted near the front, or it may be employed on the rock garden. It requires moderately light, well-drained soil and a position fully exposed to the sun.

This Erigeron is not rampant in growth—a factor which makes it specially suitable for the rock-garden — but forms a compact clump of rich green, long-petioled leaves, oval in shape and about four inches long. The flowers are about one inch in diameter and are produced singly on rather stout, leafy, branching stems fifteen inches or so high, the flower stems having leaf-like, clasping bracts at their bases.

Although E. aurantiacus does not flower so profusely as many of the better known species, or the garden hybrids, it is yet very desirable, for its vivid blossoms are produced in continuous succession from mid-June until the end of July. It is hardy if grown under conditions as suggested, and may be increased by division. *Kent.*

DICTAMNUS ALBUS.

OF graceful and stately habit, Dictamnus albus, a member of the Natural Order Rutaceae, is undoubtedly one of the oldest and best of our hardy herbaceous perennials. Native of Europe, it was introduced in 1596, since when it has proved itself to be a very useful border plant. Its common name, Fraxinella, is derived from the fact that the leaves closely resemble those of the Fraxinus (or Ash) in appearance.

The large, white flowers are borne in long, terminal racemes to the height of two to three feet. Each individual flower consists of a calyx of five sepals; five stalked petals, the uppermost four being erect, while the lower one is declined; ten stamens, which are declined, but upwardly curved and are usually equal to or exceed the petals in length, and a five-lobed ovary.

The leaves are impari-pinnate and exstipulate, and the leaflets, of which there are four to six pairs, are ovate and serratulate. The main stems are winged between the pairs of leaflets.

The peculiar phenomenon concerning this plant is that the outer parts of the flowers are covered with oily or resinous glands, and in the still of the evening following a bright, sunny day, the application of a lighted match to these parts produces a gaseous flare. Incidentally, this does not appear to damage the plant materially.

Both the flowers and foliage of Dictamnus albus are fragrant, and the odour is not unlike that of the Lemon. If crushed, however, the leaves produce a far stronger and much less pleasant smell.

This handsome plant, flowering in May and June, thrives well in any ordinary soil, but prefers a rather dry, sunny position. Propagation may be effected by seeds sown about three-quarters-of-an-inch deep in the open, directly after gathering, or by division in October or March. Fleshy root cuttings may also be taken, but as this plant is free-seeding, propagation by seeds is by far the best method of increasing a stock.

Varieties of Dictamnus albus include var. himalaicus, var. tauricus and var. purpureus (Burning Bush), the latter, a purple form, being perhaps the best. *Reginald E. Moore, University Botanic Garden, Cambridge.*

TREES AND SHRUBS.

MENZIESIA PILOSA.

ALTHOUGH not a showy shrub, this North American species is one that will appeal to all interested in Ericaceous plants. It is by no means new, having been introduced in 1806, but it is rarely seen in gardens, having doubtless been outclassed by somewhat similar members of the Enkianthus family. M. pilosa is a deciduous shrub, not exceeding four feet in the light soil of my Heath slopes. The alternate leaves are about two inches long, half as wide, and hairy, especially on the upper sides. During May copious clusters of pendulous blossoms are produced at the ends of the previous year's shoots. The bell-shaped corollas are a pale greenish-yellow, tinted with rose at the mouth, and about one-quarter-of-an-inch long. In habit the shrub is rigid and upright, the old bark often hanging in shreds from the rather sparse branches. Although the flowers are scentless, they are exceedingly attractive to bees and other insects. *J.*

ATRAPHAXIS MUSCHKETOWII.

THIS deciduous shrub is not often met with in private gardens and is, in fact, seldom seen outside botanical collections, for it is not of sufficient merit to justify planting in gardens where space is limited. Nevertheless, it is not without interest, and is the most attractive of its small genus, which is of special botanical interest in being one of the few genera belonging to the Natural Order Polygonaceae, composed of hardy, woody shrubs.

The several species of Atraphaxis are found scattered throughout south-eastern Europe and central and western Asia, A. Muschketowii hailing from the Thian Shan range, central Asia, where it was discovered by Krassnov, and was received at Kew, from Russia, in 1880.

It is a shrub of loose, rather ungainly habit, the older branches, which peel their bark, becoming barren as they age, the young shoots being clothed with alternate, narrowly ovate leaves which are up to two-and-a-half inches long, tapering at both ends, smooth and pale greyish-green, and with crinkled margins. Each leaf is furnished with two stem-clasping stipules, which terminate in spur-like points one each side of the stem. The flowers of A. Muschketowii, although they may hardly be termed striking, are yet daintily attractive, for they are star-like in appearance owing to the spreading stamens and are produced in dense racemes an inch or more long at the ends of the previous season's growths during early June. They are white, and are about one-third-of-an-inch in diameter, while they are made more conspicuous by the purplish-rose-coloured anthers and ovary

This shrub requires to be planted in well-drained, rather sandy soil, in a sunny position; it is not difficult to establish if young specimens are planted, but old plants resent disturbance and do not transplant well. It may be propagated by cuttings of young growths taken in early summer and rooted under glass. *W.*

PACHYSTEGIA (OLEARIA) INSIGNIS.

PACHYSTEGIA insignis, which is probably better known as Olearia insignis, is a remarkably handsome plant, quite unlike any of the other Daisy-trees found in New Zealand. This striking plant (Fig. 4) had been included among the Olearias until Cheeseman created the genus Pachystegia for its reception, when publishing his second edition of the *Manual of the New Zealand Flora*. Probably his interesting comments on the matter had better be quoted verbatim. "A monotypic genus confined to New Zealand. It is closely allied to the Australian and New Zealand Olearia, in which it was originally placed by Hooker under the name of O. insignis. But Hooker himself in the *Handbook of New Zealand Flora* (1864) says that it is 'almost generically distinct from Olearia in the simple pappus of equal hairs thickened at the tip.' Later on, when figuring the species in the *Bot. Mag.* (t. 7,034), he remarks, after drawing attention to the affinity of Olearia to the genus Aster: 'Of all the many species of Olearia, however, none departs so widely from Aster as does the one here figured, which in its great ovoid involucre with the bracts in many series, and its uniseriate pappus of perfectly equal hairs, rather clubbed at the tip, departs a good deal from the typical Olearias.' Much study of the genus both in its wild and cultivated state, has fully convinced me that the two characters mentioned above—the great ovoid involucre, with its multitudinous bracts, and the uniseriate pappus, with its clubbed equal hairs—are together quite sufficient to justify the creation of a new genus."

Although New Zealand has produced many striking shrubs, it is very doubtful if any of them is more worthy of notice than P. insignis. This neat shrub is found only in the north-east corner of the South Island, where it seems to show a partiality for growing perched high up on ledges or out of clefts on rocky banks of rivers, from sea-level to 3,000 feet.

Of a pleasing habit, seldom attaining more than six feet in height, it produces many low-spreading branches, of the thickness of the finger, and very densely clothed with a thick, white or greyish tomentum, as are the young leaves, the undersurface of the old leaves, the petioles, peduncles and involucres. The thick, coriaceous leaves, which vary from three to seven inches in length and from one to four inches in breadth, are oblong to obovate in outline, and are borne in rosettes at the ends of the stout branches. The young leaves are covered with a dense clothing of tementum, giving them a charm which is all their own, and as they become mature the tomentum peels off, revealing the beauty of the glossy, dark green leaves, which are characteristic of the plant. The handsome, Daisy-like flower-heads are borne singly on thick peduncles which frequently develop a few foliaceous bracts just under the involucre.

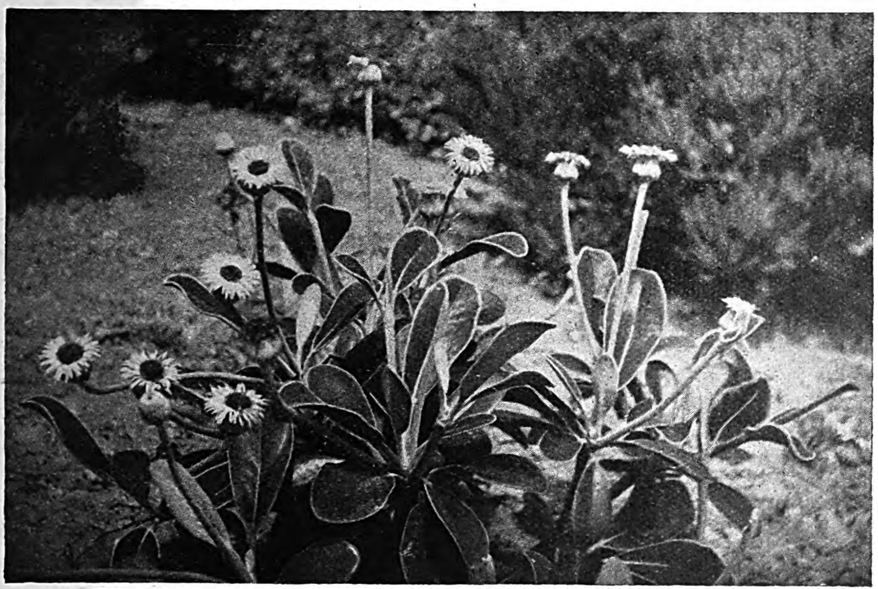

FIG. 4.—PACHYSTEGIA (OLEARIA) INSIGNIS.

There is a distinct variety of this plant in cultivation, namely, P. insignis var. minor (Fig. 5). This variety is more lax in habit, produces less tomentum, and is much smaller in every way than the type. For some time it was suspected of being of hybrid origin, but it has come true from seeds so there now seems but little doubt it is a true varietal form.

In *Trees and Shrubs Hardy in the British Isles*, Mr. Bean states that Olearia insignis is not hardy in Britain, but has proved quite hardy and seems to thrive in Ireland. Thriving in almost any soil, it is not difficult to grow, but it is a sun-lover and demands as much sunshine as possible. In its native habitat it finds a living where no nourishment would appear to be available, on the rocky walls of river gorges, etc., and therefore in the rock garden and on a dry, sunny bank should find a congenial home.

This plant may be propagated by cuttings, but owing to its neat habit, few people care to cut their plants about, and this is not really necessary because fresh seeds usually germinate freely. *Dunedin.*

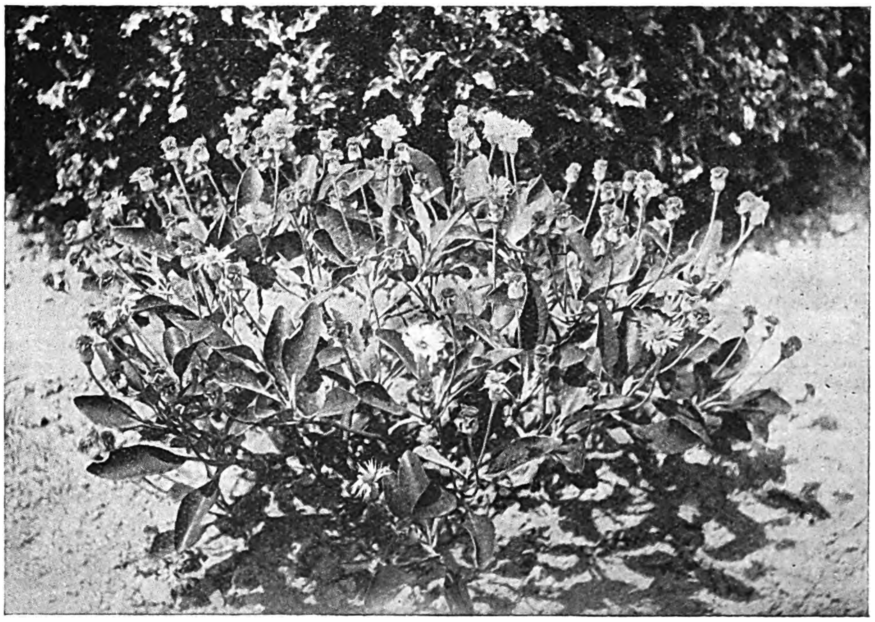

FIG. 5.—PACHYSTEGIA (OLEARIA) INSIGNIS VAR. MINOR.

RHODODENDRON HYPOLEPIDOTUM AND R. CAMPYLOGYNUM.

THE above two Rhododendrons recently flowered very freely and are quite distinct species, the latter being a type to a series which includes the Himalayan R. glaucum that is possibly better known to devotees of the genus. The chief characters of the series are: Aromatic, evergreen shrubs, usually low, compact, from less than twelve inches to a few feet high, with moderately short and twiggy growths, (not any appear gross); flowers scaly, small, fleshy; stamens downy; style short, fleshy and bent. Distribution, western China, Yunnan, Tibet, and the Himalayas.

R. HYPOLEPIDOTUM.—Seeds of this Yunnan species were sown in 1917. They germinated freely, many plants resulted, and these grew well. The best of these is about eighteen inches high and twenty-four inches or so wide. It has a loose, spreading habit. Most of the young growths made last season have terminated with an inflorescence. The leaves are obovate-elliptic in shape, one-and-three-quarter inch long, three-quarters- to one inch broad, slightly glaucous beneath, dull green above; young foliage smooth, bright green, with scattered and persistent scales. Inflorescence lax, six-flowered; corolla short and widely campanulate; colour yellow; style slightly bent, shorter than the corolla tube; stamens ten, hairy.

R. CAMPYLOGYNUM.—This western Chinese and Yunnan species has been in cultivation for a dozen years or more, yet it does not appear to be intimately known. It is one of the smallest members in the series and quite hardy. The habit is close and compact, adult bushes being less than a foot high, but extending more than that. The rate of growth is slow, only one to two inches annually. It is very distinguishable with its dark green foliage. The small leaves, thickly set on the growths, are shortly obovate-oblanceolate, half-an-inch long, a quarter-of-an-inch broad, glossy and dark green above and very glaucous below, with few scales, which fall early. Inflorescence only two-flowered, carried erect on firm pedicels; corolla tubular-campanulate, plum-purple in colour; shaded with deep "bloom"; style reddish and larger than the corolla tube; stamens ten, anthers golden.

A very fine plant I saw in a north Yorkshire garden was well established and in a healthy condition, which goes to prove its hardiness.

Between these two species a hybrid has been raised; this cross was made in 1924, R. campylogynum being the seed parent. It is singularly intermediate in all characters, and if the colour is not so precise and clear as in the parents, it is, nevertheless, an artistic shade, and one not found among other Rhododendrons. It gives indications of being floriferous. The habit is somewhat erect. The leaves are elongate-oblanceolate in shape, one inch long and one-third-of-an-inch broad, bright green above and glaucous beneath; scales scattered over the foliage; inflorescence four-flowered, dull salmon-red in colour; calyx, corolla, style and other botanical parts are also intermediate.

There are other very interesting Rhododendrons in the above group, notably R. aureum, R. brachyanthum and a dozen or more others much less known; yellow or greenish-yellow is the chief colour of the flowers.

A position in shade or partial shade would be the best for them; they would also be of interest if such a position could be found for them in the rock garden. *C. F. Coates, Kew.*

LONICERA PYRENAICA.

MANY of the smaller species of Lonicera may hardly be termed very attractive when in flower, but L. pyrenaica is one of the exceptions, and is specially suitable, on account of its fairly dwarf and compact habit, and its free-flowering propensities, for growing on the rock garden. A native of the eastern Pyrenees, it has been in cultivation now for nearly two centuries, and is quite hardy, flourishing, like the majority of the Loniceras, in good, loamy soil, not too heavy, and a sunny position.

L. pyrenaica is a deciduous, non-downy species and forms a compact, shapely bush up to three feet high. Its foliage is very attractive, the small leaves, obovate in shape and tapering at the base, being grey and glaucous, especially on the undersides. It flowers in early June, usually with great freedom, the blossoms, which are creamy-white, tinted with pink, and about half-an-inch across, being produced chiefly in pairs from the axils of the leaves on the short growths, and are often followed by a good crop of bright red, round berries, which brighten the shrub in early autumn. L. pyrenaica is figured in the *Botanical Magazine*, t. 7,774. *M. W.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

THE DISEASES OF LILIES.

IN 1925, Mr. L. Ogilvie, who was then on the staff of the Department of Agriculture in Bermuda as Plant Pathologist, began a systematic investigation into the causes of the diseases which had ravaged the bulb fields in the island and reduced the cultivation of L. longiflorum from a prosperous industry to one of negligible proportions—a condition of affairs which, happily, has since been reversed.*

Disease first became troublesome in Bermuda in the 'eighties, and was originally thought to be due to Botrytis, which at that time had been diagnosed and described by Professor Marshall Ward. In 1897, Mr. A. Woods, then assistant chief of the Division of Vegetable Physiology and Pathology in the United States Department of Agriculture, investigated the Bermuda Lily Disease and described the symptoms which have since been recognised as those of a mosaic disease. The science of plant pathology was then in the cradle, however, and anything like systematic research into the diseases of Lilies in the Bermudan fields was out of the question. So matters drifted on until Mr. Ogilvie not only diagnosed the disease which is known on the island as "yellow flat," but discovered the carrier in an aphis. The source of infection found, it remained for control measures to be applied, and, happily, these have enabled the islanders to recommence the cultivation of L. longiflorum on commercial lines.

In the course of his investigation of the virus disease referred to, Mr. Ogilvie found another disease of a mosaic character, which may be the same as that found by Woods in 1897. The Bermudan growers had, therefore, to contend with Botrytis, the virus disease called "yellow flat," and a mosaic disease. In a climate like that of Bermuda, the first was seldom serious, the second is now under control, and the mosaic is in process of control by "roguing." Such progress has already been made in its control that last year a higher proportion of diseased plants than five per cent. was not allowed in the fields, and growers whose stocks showed a higher proportion of diseased plants were not allowed to export their bulbs.

The mosaic disease of the Bermuda Easter Lily, as L. longiflorum var. eximium is popularly called, has been the subject of a joint paper by Mr. Ogilvie and Mr. Carl Guterman*, from which it appears that while the disease spreads from infected to healthy plants, the agent by which it is spread has not been found. Attempts to transmit this mosaic disease to healthy plants by means of the aphis which is the culprit in the case of the virus disease of the Bermuda Lily have failed, as have attempts with other insects. No better success has attended endeavours to spread the disease by mechanical transmission or contagion, as doctors would call it, *i.e.*, by binding a diseased leaf on to the stem of a healthy Lily pared "to the quick," a method successfully followed in the transmission of a mosaic disease which is common on L. auratum.

It seems, therefore, that we must await the result of further investigation before the cause is revealed of a disease which, if not so widespread in Britain as Botrytis, is none the less very troublesome. Plants afflicted with the disease show definite symptoms, of which the principal is a light and dark green mottling of parts of the leaves in a mosaic pattern which gives its name to the disease. The tips of the stems and some of the leaves are usually distorted and the plant is often stunted. It is understood that once a bulb has become infected with the disease it never recovers.

At one time it was thought that the only disease of Lilies which mattered in this country was Botrytis, and it is still by far the most troublesome; indeed, in many places the cultivation of L. candidum has had to be given up because it falls a victim to the fungus so readily. The symptoms are well-known and are never in doubt, but the incidence of the disease depends on the weather, for moisture is essential to its progress. In a hot, dry season it does no harm, and so we have the familiar phenomenon of good and bad Botrytis years, very much as we have good and bad years in the case of Potato disease.

There are other diseases of Lilies, however, than Botrytis, and these are particularly noticeable on imported bulbs of Japanese species, such as L. auratum and L. speciosum. The symptoms leave little doubt that a mosaic is present, and experience shows that bulbs which exhibit these symptoms never come to anything, and may as well be burned at once. It is important that sound bulbs should not come in contact with those that are diseased or with the soil in which the latter have been planted, or infection of the sound bulbs may result.

Until the last few years, Lilies have so rarely been cultivated under field conditions that little attention has been given to the diseases to which they are subject, and amateur growers in search of remedies have had to manage as best they can; but the recent introduction of field cultivation will doubtless bring with it problems in the solution of which growers will need the help of phytopathologists. Nothing can be done without research, and the splendid example of the Bermudan growers is a capital and convincing example of the value of it.

Growers of Lilies all over the world will learn with satisfaction that a Fellowship has been founded in New York with the co-operation of the horticultural society there, the Boyce Thompson Institute for Plant Research, Cornell University, and the New York Botanical Garden. Mr. Carl E. F. Guterman is the present holder of the Fellowship, and a summary of the work accomplished during the first year of the Fellowship—necessarily of a preliminary character—is published in the *Year Book* for 1928 of the Horticultural Society of New York. The progress of the investigations by the holder of the Fellowship will be followed with keen interest by Lily growers in this country. *A. Grove.*

THE GENUS PRIMULA.

(*Continued from p.* 466, *Vol. LXXXV*).

OREODOXA (Franch.). Mountain Chinese P.
(Obconica.)

THIS deciduous perennial species produces a tuft of hairy leaves, with oval-oblong blades about one inch long and one-and-a-quarter inch wide, rounded at the base, borne on somewhat slender, hairy stalks up to one-and-a-half-inch in length; margins irregularly toothed. Flower stem rather slender, hairy, one inch to two inches long, bearing an umbel of four to seven rose-coloured blossoms on slender stalks up to three-eighths-of-an-inch in length. Corolla half- to five-eighths-of-an-inch across; lobes broadly heart-shaped, notched; tube about five-eighths-of-an-inch long, much longer than the calyx. Not in cultivation.

Grows in shady places on the mountains near Mupin, in Yunnan, western China.

Culture: As for P. obconica.

ORESBIA (Balf. f.). Cut-leaved P.
(Souliei.)

An attractive, graceful, perennial sub-species of P. Souliei (Fr.), with a tuft of thin leaves about two inches long, with oval or elliptic blades about three-quarters-of-an-inch long, contracted into a wedge-shaped stalk; margins deeply cleft into oblong, toothed lobes each terminating in a sharp point; upper surface green, covered with obscure, capitate glands; underside covered with intensely white meal. Flower stem four to five inches tall, densely covered with white meal, fairly stout, erect, bearing a somewhat one-sided umbel of five or six slightly nodding, lilac flowers. Corolla more or less concave, about half-an-inch across, densely covered with white meal; segments broadly heart-shaped, bifid; tube cylindrical, about three-eighths-of-an-inch long.

Grows in rocky pastures near the summit of Yo-Chow, in Hunan, at about 10,000 feet above sea-level.

Culture: Good fibrous, calcareous loam, in a moist but well-drained open spot, is suggested.

ORESTORA (Craib). Bhutan Hill P.
(Denticulata.)

A dwarf biennial, or at times perennial sub-species of P. atrodentata (W. W. Sm.), with a rosette of pale green, spathulate or oblong-spathulate leaves about one inch long springing from a small rootstock clothed with the dried remains of the leaves. The blades are elliptic or elliptic-oblong, rounded at the tip, with their margins revolute when young, flat when mature, and furnished with regular, sharp, saw-like teeth; upper surface convex, clothed with minute, meal-producing, glandular hairs; underside densely covered with white meal. Flower stem one-and-a-half inch to three-and-a-half inches tall, densely covered with white meal above and bearing a head of about nine stemless, erect, purple blossoms with yellowish-white tubes. Corolla about half-an-inch across, flat, with egg-shaped, bifid lobes; tube cylindrical, dilated upwards, about half-an-inch long. Flowers from May to July.

Grows in damp mountain pastures and on hillsides in peat in Bhutan and south-eastern Tibet, at about 16,000 feet above sea-level.

Culture: As for P. denticulata.

OSSETICA (Kusnetzow). Ossetien P.
(Farinosae.)

A dwarf, thin-leaved perennial species closely allied to P. auriculata; it produces a rosette of egg-shaped, or egg-shaped-spathulate leaves one to one-and-a-half inch long, rounded at the tip and more or less stalkless; margins furnished with narrow, blunt teeth; underside thickly covered with yellow meal. Flower stem one inch to three inches tall, bearing a few-flowered umbel of violet blossoms. Corolla half- to five-eighths-of-an-inch across; lobes heart-shaped, very deeply notched; tube cylindrical, about as long as the calyx.

Grows in damp, open situations, in the alpine regions of the central Caucasus.

Culture: As for P. farinosa. *A. W. Darnell.*

(*To be continued*).

PLANTS NEW OR NOTEWORTHY.

KNIPHOFIA ARUSSII.*

THIS new Kniphofia (Fig. 6) is from the Arussi Mountains (7,000 to 9,000 feet), of Abyssinia. Seeds were collected by Mr. Peter Haig-Thomas in October, 1913.

The leaves are long, narrow, tapering, glaucescent-green, glabrous, folded at the midrib, channelled on the upper and bluntly keeled on the lower face; margin finely serrulate on the younger leaves, but with a narrow, even, transparent, cuticularised margin when older; 1m. long, 1·6 to 1·8 cm. wide in the lower (widest) part. Peduncle smooth, dull green below, becoming suffused with dull red above the middle, 9 dm. long to base of raceme, 1·5 cm. thick at base, tapering to 1·3 cm. above, with two leaf-like bracts, 28 cm. and 7 cm. long, respectively, above the middle, and scattered veined bracts in the upper part, 12 to 9 mm. long. Raceme very densely flowered, 15 cm. long, ending in a short tuft of dense, scarious bracts. Floral bracts scarious, pale brown, triangular, acuminate, the mid-rib forming a darker, blunt keel on the back running up to the tip, 9 to 7 mm. long except at the tip of the raceme where they are shorter. Pedicel up to 3 mm. long. Flowers deflected; bud club-shaped, slightly constricted above the base, at first pale yellow with an orange tinge on the upper part, pure yellow before opening, about 18 mm. long. Open perianth narrowly funnel-shaped above the slight constriction, 2 cm. long; lobes broadly triangular-ovate, obtuse, erect, 4 mm. long; perianth very pale yellow, with a narrow, darker mid-line continued into each lobe. Stamens yellow, exserted, of different lengths, the longest, after anther-dehiscence, projecting nearly as far as the length of the perianth. Style yellow, straight, almost filiform, tapering to the minute papillose, capitate stigma, ultimately 3 cm. long and projecting to the level of the longest, now withered stamens. Ovary 3 mm. long, narrowly ovoid in general outline, green.

This new species belongs to Berger's section Densiflorae.† It differs from the other two Abyssinian species of the section, K. foliosa, Hochst. and K. densiflora, Engler, in its long, narrow leaves. The leaves of K. foliosa reach 9 dm. in length, but are 4 cm. to 5 cm. wide at the base, while those of K. densiflora reach 5 dm. long, with a width of 2 to 3 cm.

The seeds of this plant were collected in the Arussi mountains by Mr. Peter Haig-Thomas, and sent home to his mother, Mrs. Rose Haig-Thomas, who raised plants at Ringwood, one of which was exhibited before the Royal Horticultural Society in 1916; this specimen (the type) is preserved in the British Museum Herbarium. Mrs. Haig-Thomas also gave seeds to the John Innes Horticultural Institution, where plants were raised by the late Mr. E. J. Allard, from whom I obtained a second specimen in October, 1917.

Mr. Allard wrote as follows (November, 1917):

"I raised about a dozen plants which were planted in an open spot, and most of them attempted to put up scapes late in the second year. All the scapes were destroyed by frost before reaching the flowering stage, but the plants did not suffer. I then removed all the plants to the shelter of a warm greenhouse wall, with the hope that they would flower earlier in the season. One scape was noticed to be coming in October. I potted the plant at once and placed it in a cool greenhouse and the scape you have is the result. Although the plant seems to be as hardy as most Kniphofias, its flower scapes appear too late in the season to attain full development in the open. . . . There is no attempt at a stem below the leaf tuft. . . . I might say that all the seedlings are very uniform in vegetative character. The general aspect of the plant is very ragged owing to the upper half of the flaccid leaves hanging limp, as if flagging for want of water."

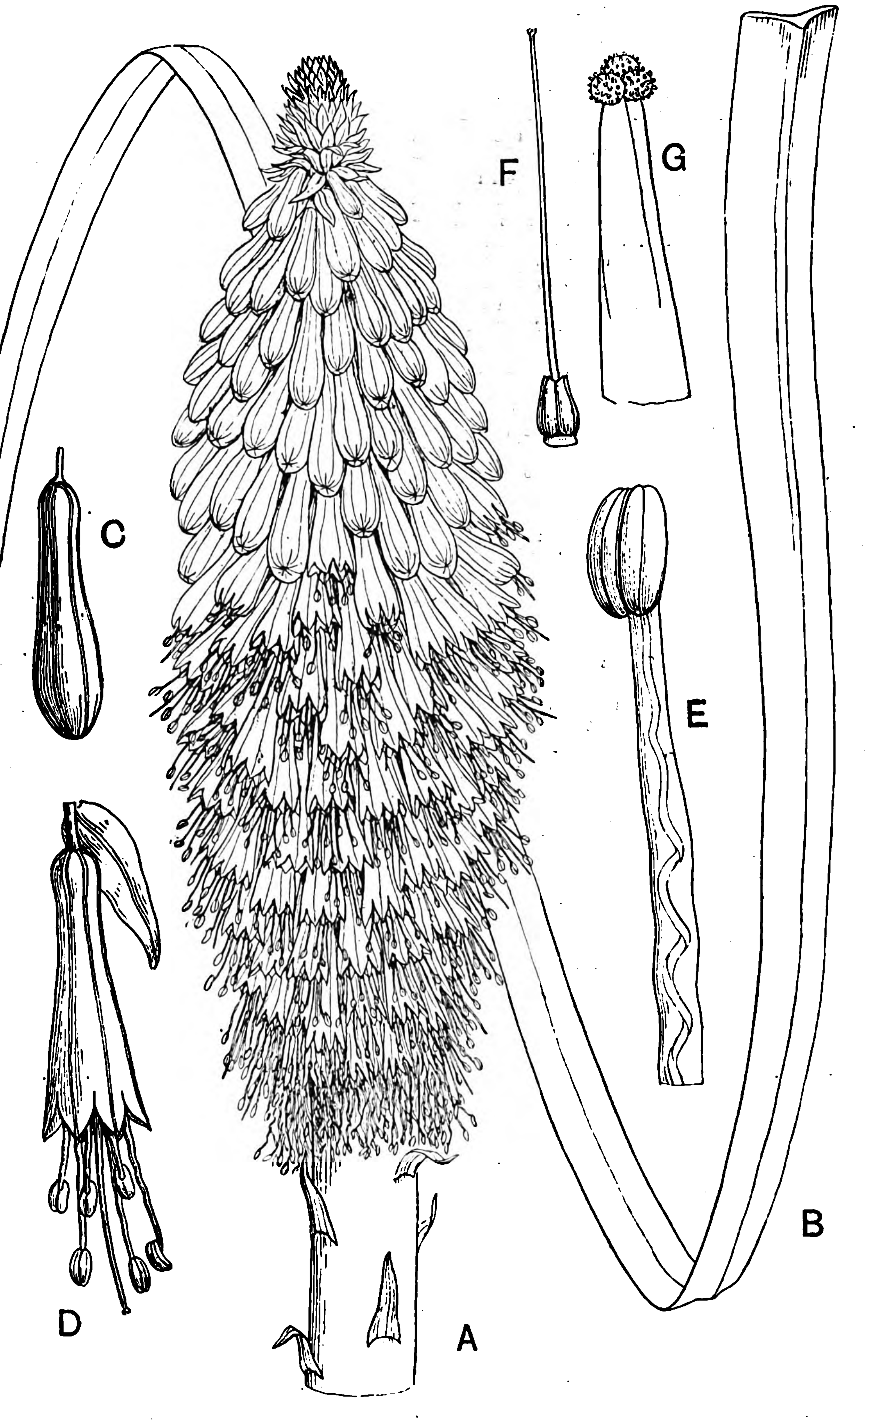

FIG. 6.—KNIPHOFIA ARUSSII.

A.—Raceme; B—portion of leaf, natural size; C—flower-bud; D—flower; E—stamen; F—pistil; G.—upper part of pistil with style, more enlarged; C-G—enlarged.

My description was drawn up from the living specimens supplied by Mrs. Haig-Thomas and Mr. Allard, and the drawing was made by the late Mr. Percy Highley from the second specimen in October, 1917. Description and specimens were laid aside until recently. I am indebted to my assistant Mr. J. E. Dandy who has kindly compared the material of the genus in the Kew Herbarium. *A. B. Rendle, British Museum (Nat. Hist.), June 22, 1929.*

---

* Kniphofia Arussii, Rendle, sp. nov. *Folia* numerosa metralia lineari-angustata, apice subacuta, dorso obtuse carinata, multinervia, ad margines anguste cartilagineos juventute serrulata demum laevia. *Pedunculus* validus 9 dm. longus, bracteis binis foliaceis instructus et in parte superiore bracteis scariosis sparsis deltoideis acutis vestitus. *Racemus* densissimus, dum florens anguste obovoideus, 15 cm. longus, bracteis scariosis pallide brunneis acuminatis uninervius; pedicelli brevissimi deflexi. *Florum* gemmae luteae cylindrico-clavatae, supra basin leviter constrictae. *Perigonium* super constrictionem tubuloso-infundibuliforme, 2 cm. longum, lobis 4 mm. longis late triangulari-ovatis obtusis, pallide luteum colore saturiore lineatum. *Stamina stylus que* valde exserta.

FASTIGIATE AND PYRAMIDAL TREES.*

OF the aberrant types of hardy trees, those with pendulous branches are probably the most popular in gardens, especially as isolated specimens on lawns. They are often, indeed, very attractive, particularly in association with the straight lines of buildings; some of them also make pleasant shady arbours for garden seats in summer time.

The value of fastigiate trees, with their slender, erect, often rigid shape, on the other hand, resides entirely in the effect they produce in the landscape. On a level, uniform tract of land, like that of Kew, they fill an attractive

---

*An article by Mr. W. J. Bean, reproduced from the *Kew Bulletin of Miscellaneous Information*, No. 4, 1929, by permission of the Controller of H.M. Stationery Office.

rôle in relieving flat, comparatively low masses of vegetation. One cannot walk around the Gardens without feeling how much the landscape owes to the Lombardy Poplar—the commonest and perhaps the best of them all. How greatly, for instance, the charms of the Lake are heightened by groups of this tree at the south-west end.

Nearly every common tree has produced a fastigiate, or at any rate, a pyramidal "sport." The Ash, the Lime and the Sycamore are exceptions and, except for a single tree at Aldenham, the common Elm appears to be another. The genus Ulmus, is, however, well represented in this respect by the Wheatley Elm, one of the U. nitens group. There already exists in Kew a practically complete collection of these trees (apart from Conifers), but they are growing in their respective collections and a general inspection of them would necessitate a rather lengthy pilgrimage. In view of the interest taken in them by tree-lovers at the present time, it has been thought desirable to assemble as many as possible in one readily accessible spot, so a commencement has been made on the western side of the Kew Palace Lawn, not far from the Sundial, where several trees of various kinds have been planted recently. To these it is proposed to add as occasion offers.

Fastigiate trees are not planted so freely as they might be in small gardens in the outer suburbs of London and other cities, where space for the typical forms is not available. A selection of a few of the best would add greatly to the interest of such places, besides providing an agreeable diversity in the vegetation. They are also especially adapted for planting on the sides of roads, where there is insufficient space for the ordinary type of tree.

Although fastigiate trees are usually, and most conveniently, propagated by grafting or by cuttings, some of them have the power of transmitting their distinctive peculiarity to their progeny raised from seeds. The Cypress Oak, for instance, raised from its own acorns, comes partially true, and the Lombardy Poplar, although a male tree, has, by means of its pollen, transmitted its columnar shape in some measure to its hybrid offspring.

Whilst most fastigiate and columnar trees are aberrant forms, a certain number of genuine species assume the same shape; among them may be mentioned Acer Lobelii, Libocedrus decurrens, Prunus Simonii, Ulmus stricta (the Cornish Elm), Magnolia salicifolia and Acer glabrum.

The commonest of all fastigiate trees is the Lombardy Poplar, Populus nigra var. italica. Its abundance is due to the facility with which it can be propagated by cuttings and its consequent cheapness, also to its easy cultivation and adaptability to different soils and climates. The facts of its origin are not precisely known and can now only be guessed at, but it seems to have appeared first on the banks of the river Po, probably (according to Henry) early in the eighteenth century. It is believed to have been introduced to England by the Earl of Rochford in 1758. It is now spread widely over the temperate regions of both hemispheres, attracting and pleasing the eye wherever it may be by its dominating height and slender shape.

It is similar to the ordinary Black Poplar, P. nigra, in leaf and twig, although occasionally pubescence may be found on the bark and leaf-stalks of vigorous young shoots. When young it has a tapering, spire-like form, becoming columnar with age. The true Lombardy Poplar is always male.

It was introduced to France in 1749 and eventually became popular as a road-side tree there. Lately it has given place in that country to some of the hybrid Poplars. Writers of historical novels are occasionally guilty of an anachronism in describing it as lining the French roads in Plantagenet times. It is now being planted in considerable numbers along the new arterial roads of England in flat, low-lying, moist localities, and in such places should provide very striking effects in a few years' time. A very frequent application to Kew is for advice in regard to the best tree to plant for hiding from view unsightly buildings or other objects that have suddenly sprung up within sight of the applicant's windows. For accomplishing this quickly, we are unable to recommend anything better than a double row of Lombardy Poplars. They form a complete screen when in leaf, and although not so efficacious as an evergreen would be in winter, the branches are clustered so closely together that they make, even then, a useful screen. In good moist soil they are capable in their early years of increasing in height at the rate of six feet annually.

Although the true Lombardy Poplar, as noted above, is a male, there are trees approximating it in shape which are female. There is one near Kew Palace which often sheds its cottony inflorescences during the summer; it is not so slender in shape as the male and may have originated as a seedling from a female Black Poplar fertilised with the pollens of the Lombardy.

The Director informs me that he noticed a large Lombardy Poplar in the Botanic Gardens, Christchurch, New Zealand, with a sporting branch high up on one side showing a loose, spreading branch like that of the ordinary Black Poplar. Photographs and specimens of the tree have been sent to Kew by Mr. James Young, Curator of the Christchurch Gardens. Mr. Young writes that he has struck cuttings from the sporting branch and that the plants, which are now three years old, do not show any signs of the fastigiate habit. This occurrence appears to be unique.

In Algeria the Lombardy Poplar develops a remarkable white bark on the trunk and the same thing has been noticed in Asia Minor and Serbia. Mr. L. A. Dode, of Paris, has named these white-stemmed Poplars P. thevestina, but they do not differ in botanical characters from the Lombardy Poplar. The white bark is probably due to some climatic condition; trees raised from cuttings brought from Algeria by the Director in 1910, and now growing in the collection of Poplars, show very little development of this character as yet.

P. nigra var. plantierensis originated as a chance seedling in the nursery of Messrs. Simon-Louis, at Metz. Similar in growth to the Lombardy Poplar, it is distinguished by its pubescent leaf-stalks and young shoots, for which reason it is assumed to have originated as a hybrid between the Lombardy Poplar and var. betulifolia, a variety of the Black Poplar marked by the same pubescence. A tree of var. plantierensis in the Poplar collection is thirty-eight feet high.

P. alba var. pyramidalis, "Bolle's White Poplar."—Compared with the Lombardy Poplar in mode of growth this tree, although quite fastigiate is considerably wider in proportion to its height. It is, of course, a form, differing only in habit, of the "Abele" or common White Poplar. It appears to be of natural origin and to have first been noticed in 1841, "forming a little grove on the bank of a brook on the north side of the Karataw Mountains between Bokhara and Samarcand" (*Garden*, December 10, 1887, p. 543). A tree at Kew near the site of the Sun Temple was measured by Elwes and Henry in 1910 and was then sixty-seven feet high; they regarded it at that time as the finest in England. It is now well over seventy feet high with a trunk girthing six feet nine inches. The pure white undersurface of the leaves gives a lively effect when they are moved by the wind and the tree may be regarded as one of the most ornamental of these fastigiate trees.

Acer saccharum var. monumentale is a very distinct variety of the Sugar Maple, introduced from the United States to Kew in 1888. It is now thirty-one feet high and two-and-a-quarter feet in girth of trunk. It is notable for its columnar shape, due to the shortness of its side branches, which take an upward direction but are not strictly fastigiate.

A Maple of somewhat similar growth is Acer Lobelii, but this is a good species, native of South Italy. It is related to the Norway Maple (A. platanoides), of which it has, by some authorities, been made a variety.

Aesculus Hippocastanum var. pyramidalis is a well-marked form of the common Horse Chestnut, with stiffly erect branches. It is, however, of a broadly pyramidal shape and not at all columnar. There is a good example in the collection near the Refreshment Pavilion, twenty-five feet high.

Alnus incana var. Balfourii.—We have recently received from Mr. F. R. S. Balfour a parcel of grafts with an accompanying letter, dated April 5, in which he says: "When in Norway two years ago, fishing in the Gloppen River, I found a tree of Alnus incana quite fastigiate and growing wild in a thicket. I marked it down and hearing that you are forming at Kew a separate collection of fastigiate trees, I wrote to Norway with the result that this package of twigs has been sent to me by Mr. Siverston, of Sandané, Nordfjord." The twigs have been used both as grafts and as cuttings and we trust this interesting Alder may be added to our collection in due course. It appears to be a quite new addition to fastigiate trees.

Betula verrucosa var. pyramidalis.—This, the fastigiate White Birch, is one of the most conspicuous trees in the collection at Kew. The best example, obtained from the nursery of Messrs. Dickson, of Edinburgh, in 1878, is sixty feet high, of slender columnar shape, with a trunk girthing three feet two inches. The variety is rarely seen in gardens, but is certainly worth planting as one of the most effective of fastigiate trees.

Cárpinus Betulus.—There are two fastigiate forms of the common Hornbeam—columnaris and pyramidalis. Both are characterised by a thick clustering of erect branches and twigs, but the former is the more slender of the two and would make a useful street or wayside tree.

Crataegus monogyna var. stricta.—This curious variety of the common Hawthorn produces a dense head of erect branches which is very distinct from the typical tree. It can scarcely be called elegant, as its shape is in no way slender, but rather broad and massive. There are two trees, the larger thirty-two feet high, which have long been in the collection of Thorns at Kew, and which flower with all the freedom of the common Hawthorn.

Castanea sativa var. pyramidalis.—The only form of Sweet Chestnut known to us that approaches the pyramidal shape is one which was found by the late Mr. W. Goldring in the grounds of Mount Mascal, Bexley, Kent. He obtained grafts for Kew and it is now represented in our collection by a young tree twenty-two feet high. It is not strikingly pyramidal, but its branching is erect enough to distinguish it amongst its allies.

Fagus sylvatica var. fastigiata, the Dawyck Beech.—The representatives of this Beech at Kew have all been raised from grafts presented by Mr. F. R. S. Balfour, in whose garden at Dawyck, near Peebles, a tree has long been growing. It is the only old specimen known to us in the British Isles, and is figured by Elwes and Henry in *The Trees of Great Britain and Ireland*, Vol. vii, plate 406, under the varietal name Dawyckii. The name, however, must give place to the older one given above.

The Dawyck Beech is a slender, strictly fastigiate tree, and Mr. Balfour's specimen is over fifty feet high; except for a thick cluster of branches which give it a broad, bushy base, it is very like a Lombardy Poplar in form. The young trees at Kew, the largest of which is thirty feet high, are of even more slender shape. The leaves are smaller than those of common Beech. Mr. Balfour informs us that his tree originated in the neighbourhood of Dawyck, and it possibly differs from the Beech originally named fastigiata by Koch, which I have not seen.

Koelreuteria paniculata var. fastigiata.—In April, 1888, Miss Corner, of The Grove, Hammersmith, sent some seeds labelled "Koelreuteria paniculata" to Kew with the information that they came from Shanghai. From them was raised a tree now growing in the collection of Sapindaceae near the Ruined Arch. It is twenty-eight feet high and one of the most strictly fastigiate trees in Kew, the spread of the branches being only thirty inches at the widest part. I can find no record of a fastigiate Koelreuteria in the standard works of Elwes and Henry, Schneider or Rehder. It would seem probable, therefore, that this rather remarkable tree has originated at Kew.

Liriodendron Tulipifera var. pyramidale.—All the forms of the Tulip Trees are interesting on account of the unique shape of the leaves among hardy trees, and this one, with its erect branches, is doubly so. It is a slow-growing tree compared with the type, and the largest one at Kew is only twenty-two feet high, although it has been grown in the collection of Magnoliaceae in the Berberis Dell for nearly thirty years. The finest tree known to me is in the old-established nursery of Messrs. Simon-Louis, at Metz; when I saw it there over twenty years ago it was a shapely spire thirty feet high.

Morus alba var. fastigiata.—This variety of White Mulberry has a narrowly pyramidal shape and is further distinguished from the type by the leaves being often more than usually lobed. At Kew, like other forms of White Mulberry, its young shoots are almost invariably cut back by winter frost, and this depreciates its value as an ornamental tree.

Prunus Lannesiana var. erecta.—This is a very curious form of the Japanese Cherry, forming a cluster of perfectly erect stems. It is known to Japanese gardeners as "Amanogawa." The flowers are pale pink, single or semi-double, fragrant, and it has the distinction, rare among the Japanese Cherries at Kew, of producing occasionally quite good crops of small, black fruits. Wilson describe it as "very beautiful," but I have not seen any trees in this country that deserve that epithet, although Mr. Lowinsky used to grow a goodly number of them in his garden at Tittenhurst, Sunninghill.

Fastigiate trees belonging to the genus Pyrus occur in the Rowan (*P. Aucuparia*), and in *P. pinnatifida*, both of which are attractive trees in their ordinary shape. These varieties only differ in their narrow shape, but this may enable gardeners whose space is restricted to find room for them.

Quercus pedunculata var. fastigiata.—This, the "Cypress Oak," occurs in a wild state in several localities in France and Spain, and a tree at Herrenhausen, in Hesse Darmstadt, originally found in a forest there, was doubtless also of natural origin. This tree was described and figured in *The Gardeners' Chronicle* for 1842, p. 36, and measured at that time nearly ninety feet in height and nearly twelve feet in girth of trunk. It appears to have been the parent of many continental and English trees, but is probably no longer in existence. A fine specimen in the park at Wilhelmshöhe, near Cassel, which originated as a graft from this tree, is now over 100 feet high. There are several trees at Kew, the best of which is fifty-five feet high; it was planted in the collection of Oaks in 1871, and in 1897 was about forty-five feet high. It is not, therefore, a quick grower. The habit of the tree is slenderly columnar. As has been mentioned previously, it comes true to a small extent from seed, and some sub-varieties have been raised in this way; sub-var. contorta has its young branches crooked and twisted, and sub-var. Grangei is a seedling that has partially reverted to the type and thereby becomes pyramidal rather than columnar. Except that it is slow-growing, the Cypress Oak would be useful as a roadside tree, especially where lateral space is restricted. In such a place it would not only make, eventually, as striking a feature as the Lombardy Poplar, but would be likely to have a much longer life.

Robinia pseudacacia var. fastigiata.—This remarkably distinct form of the common Acacia or Locust Tree is one of the most slender in habit of all this class of tree. A good example in the collection of Leguminosae at Kew near the Pagoda is fifty-five feet high, and eight feet in width. I do not know whether its origin is anywhere recorded, but it has been in existence for at least eighty years. It is, nevertheless, one of the rarest of these fastigiate trees.

There is a variety of the common "Acacia," known as monophylla, in which the number of leaflets to each leaf is reduced often to one (but also to two or three). This also has sported into a fastigiate form (monophylla fastigiata). It is not so slender as the other.

Elms.—The "Wheatley Elm," Ulmus stricta var. Wheatleyi, is the best known and most valuable of pyramidal Elms and is now being extensively planted as a roadside tree. There are two forms in cultivation that differ in habit, one having a much closer, more erect branching than the other. The best tree at Kew, obtained from Messrs. Lee's nursery just fifty years ago, is now sixty feet high and four feet four inches in girth of trunk. An even finer one grows in the Terrace Gardens at Richmond. There is also a yellow- leaved form of the Wheatley Elm.

Ulmus montana has a variety called fastigiata that is commonly known as the "Exeter" Elm, through having been found in or near that city by a Mr. Ford about 1826. There is a fine tree of it in the Vicarage garden at Bitton, near Bristol, seventy feet high. Its branches grow erect and the leaves, smaller than in the type, are often clustered at the end of the shoot. On the whole it is not particularly attractive.

The commonest and best known of all evergreen fastigiate trees is the Irish Yew, which, as is now well known, was first found in the mountains of Fermanagh about 1780. Presumably it was of natural origin and grew from seed on the spot where it was discovered, but it is curious that two plants of the same mode of growth were found. Aberrant forms of seedling origin usually come as individuals. Both the wild plants were transplanted, one to the garden of the man who found them, the other to Florence Court. The former died, but the latter still lives and is the ultimate source, no doubt, whence most or all the Irish Yews that now exist were derived. In the young state the plant is of columnar form, but with age becomes broad at the top, sometimes of an inversely pyramidal shape. In old gardens it has often been planted in avenues or formal arrangements, but although entirely distinct from any other tree, the effect of a number of specimens in association is rather dismal. It has sported into a sub-variety with golden young leaves called fastigiata aurea.

The Florence Court Yew is a female and its flowers, when fertilised with pollen from common Yew, have produced seeds from which plants have been raised that show its influence in an intermediate type of growth. The variety called cheshuntensis is one of them.

In the *Kew Bulletin*, 1927, p. 254, there is an account of the discovery by Mr. W. H. B. Fletcher, of Aldwick Manor, Bognor, of a considerable number of male plants of Irish Yew growing in his neighbourhood. All of them appear most probably to have been obtained from the Barnham Nurseries, Ltd., near Bognor, where Mr. Fletcher found, in 1927, some male specimens of the golden form still in nursery quarters. But how or whence the firm originally acquired them is no longer ascertainable.

Another and fairly well-known member of the Yew family, fastigiate in growth, is Cephalotaxus pedunculata var. fastigiata. It is of Japanese origin and was introduced from that country in 1861. Like the Irish Yew it is columnar in youth, but becomes broad-topped with age. It is, of course, very distinct in its larger, longer leaves.

Two very well-known fastigiate trees amongst Conifers are Cupressus macrocarpa var. fastigiata, a form of the "Monterey Cypress," and C. sempervirens var. stricta, the "Italian Cypress." Both these are much better known in gardens than the types from which they have sprung, and both of them survive our winters at Kew, although they are not really vigorous there. This may be due, however, more to atmospheric influences than to climatic ones. A few trees of a form of the Italian Cypress recommended to us some years ago as being more hardy than the ordinary form have been planted on the south side of King William's temple. They are of very slender shape, have grown well, and up to the present have justified their recommendation. To travellers in Italy and other parts of South Europe the dark, slender spires of this tree constitute one of the most abiding memories.

The fastigiate form of C. macrocarpa is much grown in the milder parts of Britain. It grows very rapidly, makes a useful wind-break, and it is sometimes used to form tall hedges.

Of the Lawson Cypress (Cupressus Lawsoniana) there are several erect-growing, slender varieties, the most popular of which are Allumii, spire-like in shape and wholly glaucous; and erecta viridis, green and much more vigorous, and, in places where the Italian Cypress is too tender, a good substitute for it. Even better, perhaps, is the var. Drummondii, admirably represented in Mr. Neville Cooper's Pinetum near Canterbury, but apparently very uncommon.

A slender columnar variety of Thuya plicata, called fastigiata or pyramidalis, is a distinct and quite attractive form. It is represented at Kew by a tree thirty-five feet high.

Abies pectinata var. pyramidalis is a spire-like tree of arresting shape and appearance, but, like its type, it refuses to exist in the lower Thames Valley. There used to be (perhaps is now) a fine example of it in Lavallée's Arboretum at Segrez, in France; it was thirty-five feet high when I saw it there over twenty years ago. There is a similar variety of common Spruce—Picea excelsa var. pyramidata—which makes a slender pyramid.

Three forms of common Juniper are to be included in this group of trees, viz., Juniperus communis var. hibernica, J. c. var. suecica and J. c. var. compressa. The two former are similar in their tall, slender, columnar shape, and by some authorities are considered identical, but suecica is kept separate by nurserymen on account of the pendulous terminal twigs. The variety compressa, of very slow growth, is distinct from any other tree or shrub, forming as it does a dense mass of branches and silvery-grey leaves of rigidly slender, erect shape; a plant may take twenty years to grow a little over one foot high. It makes an extremely effective little shrub for the Rock Garden.

PUBLIC PARKS AND GARDENS.

The new portion of the Tabard Garden, Southwark, south London, which has been in process of formation for the past twelve months, has now been formally opened, and the whole space, amounting in all to five acres, which was acquired by the London County Council for the purpose in 1926, is open to the public. This garden is on the site of several noisome slums, the district being known as the Tabard Street area, in early mediaeval times interesting on account of its being the starting point of the pilgrimages to Canterbury immortalised by Chaucer, but in recent times notorious for its dirt, poverty and squalor. The ground is largely turfed, with a border of ornamental shrubs and flower-beds; there are also two hard-court playgrounds, one for girls and one for boys, with a smaller one for infants, provided with a sand pit and swing cradles. For the elder children there are eighteen swings, three trapezes, three pairs of rings, a dry chute, a "merry-go-round," parallel bars, and other gymnastic appliances, while drinking fountains and shelters for use in wet weather are close at hand. The slums around the garden are still being cleared, and blocks of model dwellings erected, so that when the scheme is completed, something like a "garden suburb" in one of the most crowded, and formerly one of the poorest, districts of London, will have been created.

The Duke of Norfolk, who has a large estate in Sheffield, has presented to the Sheffield Corporation, in commemoration of the attainment of his majority, the Monument Grounds, Norfolk Road, Sheffield, for use as a public recreation ground. The grounds, which for some years have been leased to the Corporation at a nominal rent by the Duke's trustees, cover about four acres and are attractively laid out.

The Middlesex County Council has agreed to make a grant of £1,395 towards the cost of the acquisition of land at Wood End Green by the Hayes Urban District Council for an open space.

The Wirral (Birkenhead) Rural District Council has under consideration a scheme for the reservation of 823 acres in twelve parishes for open spaces.

A ROOT DISEASE OF THE STRAWBERRY.

During the last few years, growers of Strawberries in Scotland and England have been considerably troubled by the dying out of the plants in the field. In Scotland the trouble has assumed especial importance in Lanarkshire, and has come to be known in some quarters as "The Lanarkshire Strawberry Disease," as if a single specific disease was accountable for the whole of it. It is, however, possible that the so-called Lanarkshire disease is not a single one, but a congeries of diseases, of which that here described is merely one. There is, as yet, no evidence that this particular disease exists in England.

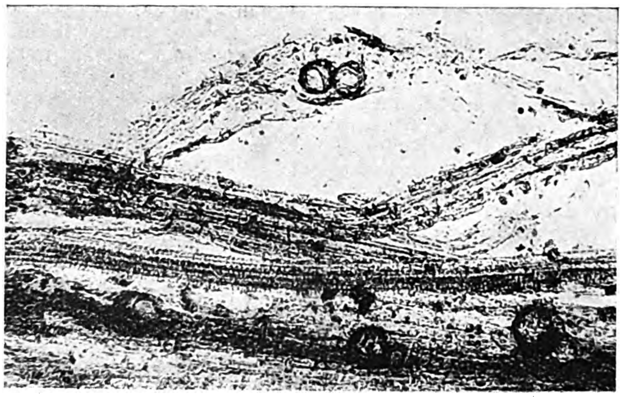

FIG. 7.—STRAWBERRY ROOT DISEASE.
Oospores *in situ*, in the central cylinder of the root; slightly teased out.

At the Royal Botanic Garden, Edinburgh, the writer has been engaged since last October (1928) in examining Strawberry plants forwarded to her by Mr. Dudley V. Howells (West of Scotland Agricultural College), who has been keenly interested in Strawberry troubles in Scotland for some time. In all, about fifty batches of plants, diseased and normal, have been examined. The diseased plants were received at approximately fortnightly intervals from October to June (1929), but the severe frost caused some interruption in the work and disturbed the regularity of the series. Including both healthy and diseased, about 250 individual plants, in all, have been examined. About one half of the batches came from the Lanarkshire area, and were selected by the sender as being definitely diseased. The other half were from the Isle of Man, north-east Scotland and the Edinburgh district, and were either selected as being definitely healthy or were, at most, regarded as being under slight suspicion.

In the diseased plants (105 in number), the characteristic signs of disease were present in every plant of every batch. The roots, or some of them, showed a definite die-back from their tips, a marked absence of laterals, of "fibrous" root formation, and, less commonly than the tip die-back, intercalary lesions, *i.e.*, discoloured areas on the surface tissues of the root, not involving the tip. The appearance of the diseased roots was very characteristic. The pale, new and rather stout adventitious roots that are put forth in late summer and autumn are those in which the disease is most clearly evident. They turn greyish-brown, the discoloration proceeding from the tip backwards.

In the tissues of the central woody cylinder of such decaying roots a fungus was invariably found. It was also found in the spring, in an apparently more active condition, in the small lateral roots that had developed meanwhile from the adventitious roots mentioned above.

The Strawberry plant itself when attacked by this disease is stunted, and the outer leaves die off. They do not become detached but remain, brown and stiff, attached to the plant. In a very bad case all the leaves die, but still remain on the plant. Any green leaves that struggle on are small in size but normal in colour. Additional crowns usually appear, and the stock becomes rather woody, but the most characteristic symptoms appear, as already described, on the larger, younger roots and on the small laterals of the older main roots. One characteristic of the disease is, therefore, the absence of small roots. In a typical case the circle of pale adventitious roots below a crown suffers first; they become discoloured and the contrast between the pale upper parts of the roots and their darkened lower ends is very characteristic. Between the blackened tip and the pale, still healthy part of the root, a brown region invariably occurs, and it is in the central tissues of this region that the fungus alluded to is most readily discovered.

The fungus proceeds upwards, and the central cylinder becomes discoloured before the surrounding cortical tissues show obvious signs of change. Hence, on scraping away the cortical tissues of an affected root with the thumb nail, a reddish core is disclosed, and growers already recognise the disease in this way.

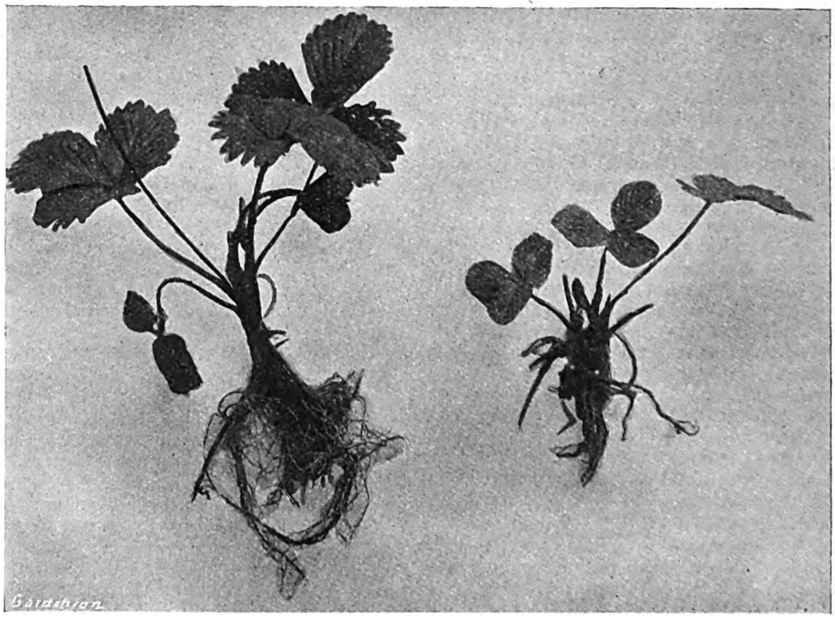

FIG. 8.—STRAWBERRY ROOT DISEASE.
Right.—Diseased Strawberry plant, artificially infected with Phytophthora. Left.—A control plant; no infection.

A constant feature of the decaying roots was found to be the presence in their central cylinders of what appeared to be thick-walled, resting spores of some fungus (Fig. 7). In some cases such spores were relatively few, but in many others they were quite abundantly present. In the earlier material it was difficult to make out details satisfactorily, but as more experience was gained and as better material came to hand, it became clear that what was present was a spherical, thick-walled spore lying within an envelope, the latter being oval or, in most cases, more or less Pear-shaped. Eventually it became clearly evident that what one was dealing with was a spherical oospore (33μ in diameter) lying within a Pear-shaped oogonium to which was attached, and clearly seen in several cases, an antheridium of definitely amphigynous type. Hence it was concluded that the fungus present was a Phytophthora.

The fungus described was found without exception in the roots of all the diseased plants and solely in them; and it was, therefore, suspected that it was the cause of the decay of the roots and the consequent stunting and ultimate death of the plants.

At the suggestion of Dr. G. H. Pethybridge, the following "infection trial" was made. To a pan of sand,* sterilised in the autoclave, portions of diseased roots (which microscopical examination had shown to contain the above described spores) were added. Seven young Strawberry runners (not from the Lanarkshire area), careful examination of which failed to disclose the presence of any disease, were planted in this mixture of sterile sand and chopped diseased roots and allowed to grow on (under glass) for six weeks. Examination at the end of this period showed that the tips of the roots of the runners, especially of the new ones that had arisen since planting, were discoloured and decayed for distances of from about one-eighth- to over one-quarter-of-an-inch from their growing points. Some of the laterals were also decaying. In the central cylinder of the diseased parts of the roots the Phytophthora was found again, both in the form of rather coarse non-septate mycelium, and of oogonia (containing oospheres or oospores) with amphigynous antheridia. Similar runners planted in similarly sterilised soil, but without the addition of chopped diseased roots, showed no decay of the roots. Figure 8 shows on the right one of the runners the roots of which became invaded by the Phytophthora, and on the left, the "control" runner.

When root material containing the parasite is placed in sterile water the fungus readily grows out and produces mycelium and sporangia with, occasionally, sexual organs. The sporangia are, on the whole, inversely pyriform, but they vary considerably in size and shape; when young they tend to be spherical (Fig. 9). No papilla is present, the apex of the sporangium being blunt, and the wall, in this region, thickened and hyaline. When a sporangium has emitted its zoospores, a second sporangium, with a longer or shorter stalk, may develop within it at its base (Fig. 10); and this process may be repeated. This behaviour is reminiscent of that described by Pethybridge and Lafferty* for Phytophthora cryptogea, and of that figured for the Phytophthora that causes the root rot of Richardia, in *The Gardeners' Chronicle*, Vol. LXXXI, 1927, p. 234, Figs. 116 to 119. It is quite possible that the present

---

* The sand employed was that commonly used at the Botanic Garden for preparing potting soil. It is not a pure siliceous material, but is essentially an extremely sandy type of soil, and is, therefore, not entirely devoid of plant nutrient material.

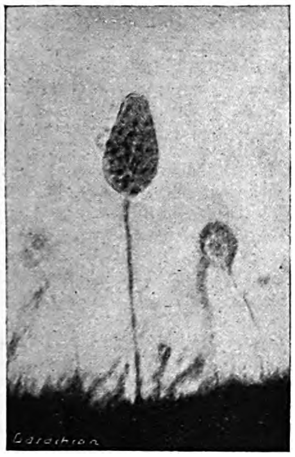

FIG. 9.—STRAWBERRY ROOT DISEASE.
Sporangium; Phytophthora type; immature sporangium on the right.

fungus may turn out to be a strain of the species named, for it appears to be a fairly common one and, the writer was informed, has recently been found at the Plant Pathological Laboratory of the Ministry of Agriculture and Fisheries at Harpenden, attacking two new hosts, viz., Tulip and Gladiolus.

The following data may be of interest to mycologists:—Oogonia average about 46μ to 47μ diameter; oospores average about 33μ to 47μ diameter; oospore wall about 4μ thick; sporangia about 50μ by 30μ.

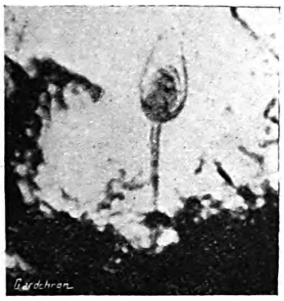

FIG. 10.—STRAWBERRY ROOT DISEASE.
Sporangium with a second one growing within.

In spite of repeated attempts, by various methods, all efforts to obtain the fungus in pure culture have so far been unsuccessful. They have been complicated by the frequent presence of an interesting species of Pythium that grows with considerably greater rapidity than the Phytophthora, but is believed to be merely a saprophytic camp-follower of it. Further work on the problem is planned, but it has seemed worth while to issue this preliminary note indicating that there appears to exist in the Lanarkshire area of Scotland a specific root disease of the Strawberry caused by a species of Phytophthora; and, if a common name is required for the disease, the designation "red core root" might very appropriately be applied to it.

In an investigation like the present, in the course of which help and guidance have been received from so many, it is difficult to acknowledge all. The assistance of the Imperial Bureau of Mycology and of the Cryptogamic Department of the British Museum (Natural History) is most gratefully acknowledged. Special help has been forthcoming from the Ministry of Agriculture's Plant Pathological Laboratory at Harpenden, of the staff of which the writer was formerly a member. Professor Wright Smith and Dr. Malcolm Wilson have both afforded assistance and encouragement, while special thanks are due to Mr. D. V. Howells and Miss Copeland for the assiduous supply of material for examination. *(Mrs.) N. L. Alcock, Department of Agriculture for Scotland, Royal Botanic Garden, Edinburgh.*

NURSERY NOTES.

MESSRS. JOHN PEED AND SON.

PERHAPS it would not be incorrect to state that by far the greatest amount of business done by this notable firm is in seeds and bulbs, which section of its activities has been greatly extended during recent years, so that there are now few parts of the world where the slogan "D'ye ken John Peed" is not known.

But besides specialising in seeds and bulbs, and plants and roots for forcing, Messrs. John Peed and Son conduct an extensive business in hothouse and greenhouse plants, and hardy plants of all descriptions.

At their Mitcham Lane nursery they have extensive collections of hardy climbers, and also grow large numbers of perpetual-flowering Carnations, pot Roses, Dahlias and bedding plants in general, and the Mordon nursery is devoted chiefly to Roses for outdoor culture, hardy ornamental trees and shrubs, fruit trees, and herbaceous and alpine plants, while at the headquarters of the firm, at West Norwood, London, S.E.27, the extensive range of glasshouses is devoted to the growing of a great variety of stove and greenhouse plants, which it was our pleasure to inspect quite recently.

Codiaeums (Crotons) are grown extremely well and in great variety at the West Norwood nursery, the extensive collection embracing such grand sorts as Eugene Draps, Edmontoniensis, Inimitabilis, Resplendent, Palais de Glace, Flambeau, F. Sander and Lady Zetland, while Dracaenas also are specialised in, sorts which we admired being Hybrida, very striking, Margaret Storry, His Majesty, Rubis, Edmontoniensis and Flambeau, all brightly coloured and very healthy.

There were grand flowering plants of various Liliums, and lovely Hydrangeas—the preparation dispensed by this firm, and known as Peed's Hydro-blue, would appear to be very effective in the production of fine azure-blue inflorescences—while such popular indoor subjects as Achimenes, in good variety; Plumbago rosea, Clerodendron Thomsonae, Bougainvilleas, of which the variety Mrs. Butt was very fine, and Nandina domestica, which makes a fine pot plant, also claimed attention during our tour of inspection.

Begonias of the Gloire de Lorraine type were being propagated by the thousand, and the many specimen plants of variously and brightly coloured Coleuses, also the Gloriosas, occupied prominent positions in the glasshouses, but grandest of all were the Streptocarpuses and Gloxinias, which filled several houses and were in full bloom, providing a veritable feast of colour.

Messrs. John Peed and Son have a grand strain of Streptocarpus, the results of years of selective work, and there would appear to be a big demand for their seeds, judging by the number of plants grown, and which we were able to see at their best. They embrace every shade of colouring, from pure white to deep crimson, with many delicate shades of salmon, lavender, lilac, and mauve to deep rosy-purple.

The Gloxinias, on the other hand, are all named, so that we were able to admire them individually and endeavour to select those which we considered of outstanding merit—a difficult task. However, it was impossible not to notice Fire King, whose velvety trumpets were vivid, orange-scarlet, and Brilliance, rich red, plum-shaded at the throat. E. L. Peed has rich plum-coloured blooms of grand form; Countess of Warwick is delicate pink with a white throat, and the frilled blooms of Mrs. John Peed are white, edged with rich lilac. Other sorts which made special appeal were Princess of Wales, Countess of Crewe, deep rose with a cream-coloured throat; Purity, clear white, without a blemish; Empress of India, with large, well-shaped, velvety, royal purple flowers; and Leslie Fletcher, purple spotted, with clear white margins.

In addition to the above collection, there were several striking unnamed seedlings—about 15,000 Gloxinia seedlings are raised each year at West Norwood—several of them being after the style of Brilliant, but distinct improvements even on that grand sort. Another notable seedling, of very good, compact flowering habit, had pale pink, spotted blooms, while yet another was red mottled, with a clear white margin.

It would take many pages to describe in full all that we admired at the West Norwood nursery of Messrs. John Peed and Son, and the high standard of production maintained. That such a high standard reaps its reward and is amply repaid is evidenced by the great expansion of the business of this firm during recent years, an expansion which has made necessary much reconstruction work at the headquarters, and this is now proceeding apace.

HOME CORRESPONDENCE.

Beschorneria yuccoides. — This interesting Mexican plant, a member of the Order Amaryllidae, is not often seen flowering profusely and it may therefore interest readers of *The Gardeners' Chronicle* to know that the specimen figured on p. 479, Vol. LXXXV, was planted in May, 1921 on a dry bank in poor, well-drained soil. The plant figured carried seven spikes and the longest spike reached a height of nine feet three inches. The red flower stems and green flowers are very effective. This particular plant is growing in the gardens of Villa St. George, Torquay, the residence of E. A. Le G. Starkie, Esq. *W. J. Powell, Villa St. George Gardens.*

Plants for Trial at Wisley.—In the report of the R.H.S meeting of June 25 and 26 (Vol. LXXXV, p. 481) three plants which were submitted to the Floral Committee and were recommended for trial at Wisley were inadvertently omitted. These were:—Delphinium Kelway's Lovely, with tall spikes of large, semi-double, milky-lavender and sky-blue, white-eyed flowers; Paeony Una Howard, semi-double, glowing reddish-carmine turning to pure carmine; and P. Gilded Splendour, a very large, handsome flower with deep rose-coloured guard petals and a huge cushion of broad, carmine petaloides, each one distinctly edged with gold. *The Reporter*

Exacum affine.—To my notes on Exacum affine in Vol. LXXXIV, p. 408, the following addition may be of interest. The plants raised from seeds commenced to flower in June and were estimated to continue until well into December; these expectations, however, were extended until the middle of February, giving a continuous display for eight months. This is a point worthy of consideration from an economic point of view. We have now a batch of plants, raised from cuttings, which began to flower early in May at the height of twelve inches. They were rooted in January in small pots of sandy soil—about five cuttings in each—in a tropical house propagating case, and were grown on under warm conditions until flowering commenced. Prior to being displayed in the conservatory, they were hardened to the necessary conditions. *Leonard G. Atkins, University Botanic Garden, Cambridge.*

Flowering Cherries.—My remarks as to the various authorities differing in their classification were meant to convey that the four authorities named were not *all* in agreement on every name of every species and variety, and not that Mr. Ingram differed from them in each and every species and variety. Personally, I feel he is the authority to follow among the Japanese Cherries to-day. I am glad to have his opinion as to the varieties Eva Gauntlett and Troiaya; it is what I expected. My mistake as to Ojochin and Hokusai being the same was stupid, as the matter is clearly explained in Mr. Ingram's last notes in the R.H.S. *Journal*. *Prunyrus.*

* G. H. Pethybridge and H. A. Lafferty, *Sci. Proc. of the Royal Dublin Society*, XV (N.S.), No. 35, February, 1919.

The Sweetest-scented Flowers.—I do not think any of your correspondents on this subject have mentioned Azalea arborescens as the sweetest-scented flower. This, I think would stand high in the list with most people. To me, the Vine in flower is most decidedly sweet, likewise Azaleas, such as mollis and pontica; yet a visitor here complained that these were decidedly offensive to her sense of smell! *G. H. Dalrymple, Bartley.*

GARDEN MANURES FOR JULY.

Under organised systems of intensive manuring it is, perhaps, not sufficiently recognised that the possibility of losses, particularly of nitrates, by the leaching effect of rain is a problem for serious thought, for the prevention of the impoverishment of the soil from this cause must be a fundamental part of the system if it is to be completely successful.

In the present season of low average rainfall the losses will not be great, but one can never forecast what the rainfall may be a few days ahead, and if nitrates are in the soil awaiting absorption by the plant when the energy of the crop is not sufficiently great to effect complete absorption of the available supply, losses are bound to result if heavy precipitation occurs.

The ideal system of manuring would be one in which the optimum amount of the necessary ingredients for various crops could be determined and reduced to measure. For example, if one knew exactly the amount of nitrogen that a plant could absorb in a given time to elaborate a certain volume of growth, one need not apply too light a dressing of nitrogenous manure and leave the plant hungry, nor too heavy a dressing and run the risk of loss by leaching, but would be enabled to give the exact amount required. Even if this were possible, however, it could only be standardised in theory, for in practice so many other factors influence the result, and even under the best garden practice there is danger of losses from leaching.

But the factors which influence plant growth are so variable and intricate that not even the specialised plant physiologist can state what are the perfect conditions for any single cultivated plant, or race of plants, and manuring is only one of these factors; light, temperature, moisture, soil texture and cultivation, exercise in their way equal influence in a marked degree. Yet the interdependency of these factors is subtle; the true functioning of all and each is necessary in obtaining maximum crops, and under certain conditions any one of them may have a decided limiting effect on growth. Much remains to be learned on many of these intricate processes, but, in so far as losses of nitrates by the leaching effect of rain is concerned, there is abundant evidence to show that the danger is much greater on uncropped land than on cropped land; therefore, under intensive garden cultivations a point to remember is to arrange the succession of crops so that plots of land remain uncropped for so short a time as possible.

An adequate supply of nitrates in the soil is a primary essential for rapid growth and heavy crop production, yet no plant-grower likes to think of the possibility of this potential fertility being lost through leaching, and every effort should be made to adopt means to prevent it so far as present knowledge enables one to do so. For example, early crops of Spinach and Lettuce may have been intensively fed and a considerable residue may be left in the soil in the shape of nitrates which would give an immediate fillip to a succeeding crop, but might, on the other hand, be entirely lost should a heavy thunderstorm occur while the plot is still lying vacant. If, for any reason, the succeeding crop cannot occupy the plot immediately, it is far better to grow a quick-maturing catch-crop or a crop to turn in as green manure than to let it remain vacant. The use of green manure is well-known and apart from its value in adding food to the soil, it has the further potential value that the crop may prevent something being taken out.

Adverting to the various factors which influence plant growth, their interdependency, and the partial functioning of any one factor having a limiting effect on growth, many of the processes involved are so intricate and unseen that it is difficult to follow the working of them and recognise how they may be exercising a limiting effect on growth, but the water factor provides a simple example which is quite clear. Everyone can easily see that when it is withheld below a certain degree, and likewise, when it is given in excess, the plant suffers immediately. The optimum amount to supply then, varying, of course, with the type of plant, is to that point where no further acceleration of growth ensues, and beyond which growth is depressed. The manure factor, like all other factors, has its optimum amount, and although the results may not be seen so readily as in the case of water, they are just as definite and important.

In the case of nitrogenous fertilisers at the present season, considerable discretion should be exercised, as the general tendency of such fertilisers is to excite growth unduly and retard maturation of the crop. This might be a distinct disadvantage in the case of many crops, but all forms of nitrogenous manures have not the same degree of retardation, and if it is considered necessary to apply a nitrogenous fertiliser late in the season, ammonium chloride has a less retarding effect than sulphate of ammonia. The reason for this is not quite clear, but there are many subtle points in the action of various elements and their relation to plant nutrition. Here we have the element chlorine, which is not an indispensable plant food, and can be done without according to laboratory experiments, exerting an extraordinary influence on the behaviour and growth of the plant. Many such peculiarities occur in the intricate processes leading to plant nutrition and, much as research has revealed to us in recent years, there still remains much of economic interest to unearth. *W. Auton.*

FRUIT GARDEN.

ROOTING STRAWBERRY RUNNERS.

Those contemplating the renewal of stocks of Strawberry plants by obtaining runners from distant sources, may be interested in a satisfactory method of rooting the runners at home after receipt.

In the first place, the young plants for dispatch should be severed from the runners after they have made good leaves, but before they attach themselves to the ground. Tied up into bundles of twenty-five, a large number can be packed into a box, and sent by post. If the journey is longer than twenty-four hours, a little damp moss may be put around the basal end of each bundle, but it should be merely damp, not wet.

A shallow frame containing a few inches of sandy soil should await the arrival of the plants, which should be dibbled in, about three inches apart, so soon as received, taking care not to bury the eyes of the crowns. After a good watering, close the frame and afford shade from bright sunlight. If kept close, shaded, and syringed over twice daily, the plants will root quickly, and they should then be gradually inured to full sunlight and air, eventually removing the lights, after which they may be dealt with as desired—either planted out into the garden or potted up for forcing.

For some years past, I have sent 600 young cuttings in a single parcel a journey of forty-eight hours, and, treated as advised, they have given complete satisfaction, always making splendid forcing crowns during the season. The advantages of the method are that:—the cost, both of plants and carriage, should be less than in the case of rooted stock; delivery should be obtained early in the season—an important factor in successful cultivation, but not always possible in the case of rooted runners; and, the young plants, after rooting, are not subject to the damage and check entailed in packing and travelling. *E. Brown, Hillside, Doddington, Sittingbourne, Kent.*

SOCIETIES.

GARDENERS' ROYAL BENEVOLENT INSTITUTION.

The Eighty-fourth Annual Festival Dinner of this Charity was held at the May Fair Hotel, Berkeley Square, on Wednesday, June 26, under the presidency of Lionel de Rothschild, Esq., O.B.E. Among those present were Lord Aldenham, Sir Jeremiah Colman, Sir John Young, Mr. and Mrs. L. Bradbury, Mr. and Mrs. E. Sherwood, Mr. L. Sutton, Mr. Gerald Loder, Mr. Gordon Selfridge, Lieut.-Col. and Mrs. Durham, Sir James and Lady Slade, Sir Frederick and Lady Green, Mr. H. Greenwood, Mr. and Mrs. Robins, Mr. and Mrs. McLeod, Mr. and Mrs. George H. Barr, Mr. P. R. Barr, Mr. and Mrs. J. M. Bridgeford, Mr. and Mrs. C. H. Cook, Mr. W. Howe, Mr. and Mrs. H. Miles, Mr. and Mrs. Linford, Mr. and Mrs. W. O. Hiehle, Mr. and Mrs. J. Collingridge, Mr. D. Monro, Mr. A. J. Monro, Mr. and Mrs. Walter Turner, Mr. and Mrs. F. A. Secrett, Mr. and Mrs. D. Ingamells, Mr. and Mrs. A. Bullock, Mr. and Mrs. J. Poupart, Mr. and Mrs. H. Jolis, Mr. C. H. Curtis, Mr. A. Bedford, Mr. and Mrs. F. Ladds, Mr. A. C. Bartlett, Mr. and Mrs. W. Cuthbertson, Mr. A. J. Wood, Mr. and Mrs. W. E. Wallace, Capt. Noel Sutton and Mr. and Mrs. G. H. Cobley.

A telegram conveying wishes for a happy and profitable evening was read from Mr. George Monro, who was abroad.

In proposing the toast of "Continued Prosperity to the Gardeners' Royal Benevolent Institution," Mr. Lionel de Rothschild said that the charity was only some nine years short of its centenary. It was a charity which should be supported by everyone who loved a garden, from the highest in the land to the lowest. Their Majesties had always taken an interest in the Institution from the time when Queen Victoria was its Patroness. The object of the charity—the only one of its kind in England—was to assist by means of annuities distressed and aged gardeners and their widows. For this purpose £5,500 was needed, and the assured income was only £1,200. The Committee asked not only for that amount, but also for sufficient money to begin to assist permanently the twenty-six persons on the waiting list who were deserving of help, and whose cases had been investigated. They were all people in dire need, and he really could not understand how it was there was a waiting list. Mr. Rothschild referred to the occasions on which his father had taken the chair at Festival Dinners, and he appealed to all present to help those who, through no fault of their own, had fallen on evil times.

In replying, Mr. Leonard Sutton expressed appreciation of the fact that Mr. Lionel de Rothschild should continue the interest taken by his father and uncle in the Institution. Everyone knew how much English horticulture owed to the family of Rothschild. He referred to the growth of the charity and, with the increasing number who needed pensions, the need for more money. He suggested means by which this could be raised by local collectors and referred to the losses sustained through the deaths of Lord Lambourne, and Mr. Peter Veitch. In conclusion he congratuled Mr. Gerald Loder on his election to the Presidency of The Royal Horticultural Society.

Col. Sir John Smith Young proposed "The Visitors" in an interesting speech, in the course of which he referred with pleasure to the number of small gardens that were springing up in the poorer districts "like oases in the desert." He also referred to the adoption of flower emblems to raise funds for great national causes—Poppy Day, Daisy Day and Rose Day. Sir Jeremiah Colman, Bt., responded.

Mr. Edward Sherwood, Master of the Worshipful Company of Gardeners, and Treasurer of the Gardeners' Royal Benevolent Institution, proposed the health of "The Chairman." He emphasised the connection of the Rothschild family not only with horticulture in general, but with the Institution in particular, and indeed with all institutions which had for their object the alleviation of suffering. Mr. Lionel de Rothschild, in reply, paid tribute to the work of Mr. G. Ingram, the Secretary, and said if the collection realised all that the Committee needed, there would be sufficient thanks. He referred to the planting of ornamental trees and shrubs along the highways of this country, and to the damage that was done to them by thoughtless people, and asked all present to bring home to the public the fact that it was the duty of every citizen to protect the beauty of the English roadside; if they would do so he would be more than repaid.

The principal contributions were as follow:—Lionel de Rothschild, Esq., £100; Messrs. N. M. Rothschild and Son, £105; Messrs. Hurst and Son, £105; Messrs. Sutton and Sons, £100; Mr. H. Gordon Selfridge, £52 10s.; Sir Jeremiah Colman, £30; The Royal Horticultural Society, £52 10s.; Mr. W. Cuthbertson, £50; Mr. Chas. H. Cook, Royal Gardens, Windsor, £153 11s., including £68, the proceeds from two social evenings and fifty guineas subscription from Messrs. Waterer, Sons, and Crisp, Twyford; Messrs. Wood and Son, Ltd., £100, including £10 10s. from Sir W. Paulin; Mr. Chas. H. Curtis, £39 18s. including £21 from W. Laurence Bradbury, Esq., and £5 5s. from the proprietors of *The Gardeners' Chronicle*; Mr. W. E. Wallace, £22; Mr. R. W. Wallace, £20; Mr. R. F. Felton, £21; Mr. G. F. Johnson, £47; Mr. W. H. Honess, £20; Mr. F. J. Chittenden, £16 16s.; Mr. J. G. Weston, £16; Mr. and Mrs. G. H. Cobley, £15 15s.; Mr. H. G. Alexander, £15 15s.; Mr. Arthur Bedford, £15 15s.; Mr. A. C. Harris, £8 8s.; Mr. H. H. Thomas, £8 8s.; Mr. H. B. Piper, £8 8s., and Mr. Noel Berridge, £7 7s.

Major E. G. Monro's Covent Garden List came to £287, and included Major E. G. Monro, £25; Mr. Geo. Monro, C.B.E., £25; Mr. F. A. Secrett, £21; Messrs. T. J. Poupart, Ltd., £21; £10 10s. each from Messrs. Geo. Monro, Ltd., Messrs. E. Stevens, Ltd., Mr. Alfred Watkins, Mrs. Alfred Watkins, and Mr. J. Rochford; Mr. Raymond Rochford, £7 7s.; and £5 5s. each from Mr. A. Baker, Mr. B. J. Monro, Mr. E. Rochford, Messrs. Wills and Segar, Messrs. Thos. Rochford and Sons, Ltd., Mr. Frank Segar, and Mr. S. Segar.

Mr. John Collingridge's Covent Garden List came to £230 and included Mr. F. Ladds, £25; £10 10s. each from Mr. John Collingridge, Mr. D. Ingamells, Mr. B. G. Broome, Messrs. Elder Fyffe, Ltd., Mr. H. Miles, Mr. W. H. Robins, Mr. H. F. Hannibal, Mr. W. Wiles, and Mr. H. Larsen; Mr. John Cull, £8 8s.; Mr. R. T. Bates, £6 6s.; Mr. H. Jolis, £6 6s.; and £5 5s. each from Covent Garden Properties, Ltd., Mr. W. O. Hiehle, Mr. O. Hiehle, Mr. W. Turner, Mr. W. Maxwell, Mr. A. H. Maxwell, Mr. A. Howard, Mr. A. Dimmock, and Mr. Percy Lane, and various other amounts.

Donations of £10 10s. were given by each of the following:—Lord Treowen, Lord Aldenham, Sir Guy Granet, Col. Sir John Smith Young, Lady Waley Cohen, Sir Felix Schuster, Sir Edward Stern, Mr. James de Rothschild, Mr. Henry Hicks, Major Harcourt Webb, Mr. John Weir, Mr. J. L. Kinnell, Messrs. Bentley and Messrs. Protheroe and Morris. Contributions of £5 5s. were received from Lord Leverhulme, Lord Plymouth, Lord Dewar, Lord Leconfield Sir R. Kindersley, Lt.-Col. J. Francis, Messrs. G., W. E. Loder, C. F. Langdon, F. C. Stern, G. Prickett, J. Linford, C. Langman, Stuart Low, J. M. Bridgeford, Wm. Cutbush and Son, Lowe and Shawyer, Walter Ware and Co., Ltd., J. Firmin, P. D. Williams, A. Gollin, J. P. Taylor, Mrs. Edward Sherwood, Mrs. J. W. Campbell, Mrs. F. E. Wheatley, Horticultural Trades' Association, Mr. Hubert Greenwood, D.L., Mr. H. W. Nutting, Mr. E. T. Willis and Mr. H. S. Clogg. These, with various other amounts, made a grand total of £2,500.

WIMBLEDON GARDENERS'.

ON Wednesday, June 12, the members of the Wimbledon Gardeners' Society paid a visit to the gardens of Mr. Lionel de Rothschild at Exbury. The party, numbering forty-two, travelled by motors by way of Staines, Basingstoke and Winchester. At this ancient city a halt was made; then the party proceeded to Lyndhurst, where lunch was served. The pretty village of Beaulieu was soon entered, and a short call was made on Mr. Shotter, the village schoolmaster and an ardent horticulturist. In a little while, Exbury was reached, and the members began their inspection of the beautiful garden. Mr. Findlay showed them round the ornamental grounds and was very obliging, readily answering many questions. The grounds proved to be most attractive, and many were the expressions of approval. Presently a tour was made through the glasshouses, under the leadership of the inside foreman. The houses—full of rare and interesting plants—were magnificent, embodying all the latest improvements in horticultural building. After this the visitors were taken over by the foreman of the kitchen gardens who conducted them around his special department.

Just before the conclusion of the visit, Mr. A. Bedford, the head gardener, returned from London, and was greeted and thanked by Mr. Hosking, the Chairman of the Society. The return journey was made via The Hog's Back, Guildford, Cobham and Esher.

MANCHESTER AND NORTH OF ENGLAND ORCHID.

AT the meeting of this Society held early in June, the members of Committee present were:—Messrs. J. B. Adamson (in the chair), A. Burns, A. Coningsby, D. A. Cowan, A. Keeling and H. Arthur (Secretary). Mr. T. A. Greenfield was invited to sit with the Committee.

No awards to individual plants were made.

GROUPS.

Mrs. BRUCE and Miss WRIGLEY (gr. Mr. A. Burns), Bury, staged a group to which a Large Silver-gilt Medal was awarded. It consisted of Miltonias in great variety, together with Odontoglossum Phoebus, O. Eve, O. Lutetia, O. eximium and O. harvengtense, Odontioda chelsiensis and others.

J. B. ADAMSON, Esq. (gr. Mr. J. Howes), Blackpool, was also awarded a Large Silver-gilt Medal for a group which included Odontoglossum crispum var. Coronation, O. Baron Renfrew and O. Grand Duke Nicholas; Odontioda Cereus and O. Coronation; Miltonia Hyeana var. Butterfly, M. H. var. Distinction, and others; Cattleya Mossiae, Masdevallia Bocking hybrid, and Oncidium flexuosum and O. varicosum var. Rogersii.

Messrs. CHARLESWORTH AND CO., were awarded a Large Silver Medal for a small group which embraced such choice Orchids as Odontoglossum Ascania, O. Figaro, O. Toreador, O. Celeus, O. Purple Gem and O. Gardenia; Miltonia Lena, M. Lucia, M. Elea, M. William Pitt and others.

Captain W. HORRIDGE (gr. Mr. A. Coningsby), Bury, staged Miltonia Hyeana, M. Bleuana var. Reine Elizabeth and others; while Messrs. KEELING AND SONS showed Odontoglossum Amersham, O. promerens var. xanthotes, and O. Matador; Miltonia Bleuana var. albens; Dendrobium Renown and Masdevallia Peristeria var. muscosa.

Mr. JOHN EVANS, Colwyn Bay, exhibited Cypripedium microchilum, Coelogyne Mooreana, and various Odontoglossum seedlings.

AT the Annual General Meeting, which followed the Committee meeting, Captain W. Horridge presided. The report and balance sheet for the session were adopted.

Henry Astley Bell, Esq., was re-appointed President; J. B. Adamson, Esq., Hon Treasurer, and Mr. H. Arthur, Secretary. The Executive and Awards Committees were also re-appointed.

The prizes were presented to the successful exhibitors as follows:—to J. B. ADAMSON, Esq. (gr. Mr. J. Howes), the Alexander Trophy, Charlesworth Trophy, Cowan's Trophy, Cypher Trophy, Evans Trophy, Sander's Trophy, and the Horridge Challenge Cup, the last named for the third year in succession.

The Royal Botanic Society of Manchester and Northern Counties' Silver Gilt Medal to Mr. A. Burns; and the Silver Medal to Mr. J. Howes. Mrs. Smith's prizes to gardeners: First, Mr. J. HOWES; second, Mr. A. BURNS, and third, Mr. B. COLLINS.

The Secretary regrets to place on record the deaths of Messrs. J. J. Bolton, S. Gratrix and J. Thrower, who were long connected with the Society.

NATIONAL SWEET PEA.

JULY 2 AND 3.—The Exhibition held by this Society on these dates was its twenty-ninth, and the first one it has held in the Royal Horticultural Society's new hall, which, despite its magnitude, was well filled with exhibits, and presented a very delightful picture. That this was due largely to the manner in which the exhibits were arranged cannot be questioned, and much praise is due to those responsible for the arrangement and general management of the show, and especially to the Society's able secretary, Mr. A. C. Bartlett.

Competition in the majority of the classes was keen, and, despite the trying weather conditions with which Sweet Pea growers have had to contend, the general quality of the blooms displayed was very high. Although trade exhibits were not numerous, they were very imposing, and the arranging of the various large competitive groups with them was a happy thought, and added greatly to the general effect. The Exhibition may well be described as a complete success.

On the first day of the show the President of the National Sweet Pea Society, Harold Beale, Esq., entertained the judges and chief exhibitors, and a large number of visitors, including several Sweet Pea enthusiasts from the United States, to a very enjoyable luncheon.

COMPETITIVE CLASSES.

These were very extensive, embracing in all seventy classes, and including a large number of special trophy competitions, which, in general, were keenly contested.

In Division I, open to all members, the *Daily Mail* Cup, offered for the best twelve vases of named varieties of Sweet Peas in commerce, was awarded to Major C. B. KRABBE (gr. Mr. A. W. Power), Calcot Grange, Reading, for a very fine set of really good blooms, his varieties being Blue Bird, Grenadier, Wild Rose, Pinkie, Constance Hinton, Magnet, Sunkist, Hero, Mammoth, Powerscourt, and Mrs. A. Searles. Mr. H. CHING, Elmside, Torquay, was a close second, showing Pink Delight, Powerscourt, Charming, Britannia and Bluebell in splendid condition, while Mrs. URQUHART (gr. Mr. W. Buckle), Brasted Place, Kent, was third.

In the competition for the E. W. King Cup, Mr. H. W. LININGTON, Atherfield Farm, Chale, Ventnor, Isle of Wight, was first, his twelve vases including grand blooms, in the pink of condition, of Mrs. A. Searles, Vectis, pure white; Venus, pink and cream; Mammoth, Sunkist, and Charming. Outstanding sorts in the second prize exhibit by Miss RUSSELL, Canterbury, were Model, Nina, Gold Crest, Powerscourt and Pinkie.

Miss Russell was first in Class III, for six varieties of Sweet Peas that have not been in commerce for more than one year, and so secured the Burpee Cup, her varieties being Ruffled Rose, Winnie Morse, Vectis, Ambassador, Flamingo and Reflection, and she was also first in the colour scheme class, with very attractive blooms in several delicate shades; second, Mrs. HENRY WILLIAMSON (gr. Mr. W. Langsdon), Bramhope, Canterbury, and third, Mr. W. HUFFEY, Yardley Park Road, Tonbridge.

Messrs. E. W. KING AND CO., LTD., were first in Class 5, for three vases of seedling Sweet Peas, not yet in commerce, with Souvenir, a grand salmon-cerise; Sonny Boy, mahogany-red, and Big Ben, of good form and pink and cream in colour. Mr. J. STEVENSON was second in this important class, showing perfect blooms of Purity, white; Scintillant, bright rose, and Beauty, flesh-pink. For one seedling Sweet Pea, the Southfield Nurseries were first with Michael, pale salmon; Messrs. E. W. King and Co. being second with Big Ben. The latter firm was first in the raisers' class, for six vases of Sweet Peas, distinct, raised by the exhibitor, with Leslie Rundle, Olympia, Pimpernel, Vectis, Jack Hobbs and Tally Ho. Mr. J. Stevenson was second with Purity, Scintillant, Charm, Treasure, Beauty and Lustre.

Competition in the single bunch classes in this division was very keen, and a high standard of quality was maintained throughout. Mr. R. G. Taylor, 25, Highgrove Street, Reading, was first for one vase of blue Sweet Peas, with Bluebell, of grand quality; second, Miss Russell, with Tom Webster; third, Mr. J. Stevenson, with Bluebell. For one vase of cerise Sweet Peas, Mr. H. W. Linington was first with Glorious, and he also secured the first prize for cream-pink Sweet Peas; F. W. Franks, Esq. (gr. Mr. W. Humphrey), Loampits, Tonbridge, was second in this class with Miss California; third, Mr. W. Huffey, with Picture. Miss Russell led for one vase of cream, buff or ivory-coloured sorts, followed by Mr. H. W. Linington, both exhibitors showing grand blooms of Ivory Picture, and these two exhibitors were also first and second respectively for white or cream ground, flushed sorts, the former showing Mrs. Horace Wright, and the latter, Del Monte.

For one vase of pink Sweet Peas, not cream ground, Mr. R. G. Taylor was first with Pinkie, in splendid condition, Mr. H. W. Linington being placed second, and Mr. W. Huffey, third, while Mr. R. G. Taylor also led for a vase of crimson or scarlet sorts, with Royal Scot; second, Miss Russell, with Flaming June; and third, Mr. W. Huffey, with Defiance.

The best vase of lavender or mauve Sweet Peas was shown by Mr. W. Huffey, while Miss Russell secured the premier award for maroon Sweet Peas, and also for one vase of orange or orange-scarlet Sweet Peas, with lovely blooms of Royal Sovereign. Mr. W. Huffey led for picotee-edged Sweet Peas in this section, showing grand specimens of Youth; second, Miss Russell, with Sunkist, the latter exhibitor securing the premier awards in both the white, and the "any other colour" classes, with Model and Lilac Queen, respectively.

The premier competitions in Division 2, open to the trade only, were for the Bath Challenge Cup and the Eastbourne Challenge Cup. The former was for the best exhibit of Sweet Peas grown out-of-doors, the maximum group space being 12 ft. by 4 ft. 6 ins., and this trophy was awarded to Messrs. E. W. King and Co., Ltd., who had a grand display of magnificent blooms. There were huge sheaves of Pimpernel, Tally Ho and Flamingo, and lovely baskets of Jack Hobbs, Cheerio, Big Ben, Magnet, Idyl, Sonny Boy, and others, all very tastefully arranged. Mr. J. Stevenson was responsible for an attractive group in this competition, showing grand blooms of such choice sorts as Treasure, Powerscourt, Beauty, Ascot and Charm.

The Eastbourne Challenge Cup, for the best trade exhibit with a maximum space of 15 feet by 4 feet 6 inches, was awarded to Messrs. Dobbie and Co., Ltd., who staged a very striking display, in the form of huge sheaves of Reflection, Gleneagles, Flamingo and Royal Sovereign, in the background, with dainty vases of such grand sorts as Jack Hobbs, Mrs. A. Searles, Picture, Magnet, Charm, Dainty Maid and Idyl, all in splendid condition. Messrs. Sutton and Sons also entered a very striking group in this competition, their massive pillars of Magnet, Matchless and Idyl being very imposing, while they had lovely vases of many other choice sorts.

Messrs. E. W. King and Co., Ltd., were the winners of the Monro Challenge Trophy, for twelve vases of Sweet Peas, in not fewer than six varieties, and in their grand set they included perfect examples of Olympia, Vectis, Mrs. J. B. Hobbs and Gladys; second, Mr. J. Stevenson, with Bullion, Venus, Purity, Beauty and Wild Rose, very fine; and third, Mr. H. J. Damerum.

Class 26 was the most important one in Division 3, open to all amateurs, as the first prize in this carried with it the Bournemouth Challenge Cup. A display of Sweet Peas on a 5 feet run of staging was required, and the display set up by Samuel Wallrock, Esq. (gr. Mr. W. Holloway). The Manor House, Stanmore, was deservedly awarded the trophy, for the blooms were in splendid condition and very tastefully arranged.

In the class for the Sutton Cup, F. W. Franks, Esq., was deservedly placed first, for he showed blooms of outstanding quality, his varieties being Model, Venus, Powerscourt, Gleneagles, What Joy, Glorious, Youth, Picture, Magnet, Purple Monarch and Royal Mauve; this exhibit also secured for him *The Gardeners' Chronicle* Medal. Mrs. J. T. Wigan (gr. Mr. F. Cotterell), Danbury Park, Chelmsford, was a close second, her best blooms being of Sunkist, Flamingo, Avalanche and Youth, and Samuel Wallrock, Esq., was placed third.

There was a large number of entries in the Cory Cup class, for six vases of Sweet Peas, Mrs. A. Cole (gr. Mr. L. W. Barker), Sheffield Place, Basingstoke, being awarded the trophy for a grand set, embracing Mammoth, Powerscourt, Constance Hinton, Blue Bird and Youth; second, Mrs. W. G. Thorpe (gr. Mr. W. Birches), Hucclecote, Gloucester; third, Mr. H. Williamson.

For nine vases of British-raised Sweet Peas, F. W. Franks, Esq., was placed first with a very choice selection, in which Model, Magnet, Venus and Mammoth were outstanding; the second prize was awarded to Mrs. C. Pearson (gr. Mr. C. Hodgson), Acton Place, Suffolk, while in the next class, Mrs. W. G. Thorpe was first, Mrs. H. Williamson second, and Mrs. C. Pearson third.

In the Western Counties and South Wales class (these district classes required six vases of Sweet Peas), Mrs. W. J. Thorpe secured the first prize, her best vases being of Elegance, Mammoth and Mrs. A. Hitchcock; Mrs. F. Churcher, Newton Abbot, was second. Mrs. Duveen (gr. Mr. J. Howard), Broadway, Limpsfield, Surrey, was first in the Southern Class, with fine blooms of Pinkie, Model, Youth, Purple Monarch, Mrs. A. Searles, and Powerscourt, while in the class devoted to the Midland Counties, Mr. H. C. Dawes, Mundesley, was first. The leading exhibitor from Ireland was Lord Ardee (gr. Mr. W. Barrett), Kilruddery Castle, Bray, Co. Wicklow. He had a grand set of blooms, which had withstood the journey to London exceptionally well, the varieties displayed being Charming, Royal Mauve, Sweet Seventeen, Constance Hinton, Gladys and Mrs. A. Searles; a very creditable exhibit.

Mr. H. Ching, Torquay, was first for six vases of Sweet Peas, and F. W. Franks, Esq. led for one vase of three distinct colours, while in the single vase, distinct colour, classes, the first prize winners were Samuel Wallrock, Esq., Mr. H. Ching, F. W. Franks, Esq., and Mrs. A. Cole, all of whom exhibited blooms of very high quality.

In the section for members who grow not more than 500 exhibition plants, Mrs. Zachner (gr. Mr. A. W. Richards), Oak Hill Lodge, Sevenoaks, was the most successful exhibitor, while among the members with not more than 300 plants, the leading prize-winners were Mr. B. A. Hull, Kelvedon, Essex, for twelve vases, three vases, and one vase of mixed, with some very good blooms; Mr. F. Burfoot, for six vases, which were of What Joy, Charming, Magnet, Venus, Hebe and Model; Mr. H. Monk, and Mr. C. R. Jeggs.

In the division for novices, who were very numerous, Mrs. Duveen secured the premier award for six vases of Sweet Peas, Mr. J. W. Hatcher being placed second, and Mr. C. Reid, third, while Mrs. Duveen was also first for three vases, one vase, and one vase of mixed colours.

There were several good sets of Sweet Peas in the *Amateur Gardening* Cup class, for nine vases of Sweet Peas, distinct, Mr. W. Huffey being awarded the trophy, with Mr. F. J. Rogers and Mrs. C. Pearson, second and third, respectively. The Hamilton Cup, for twelve vases, distinct, amateurs only, was awarded to Mr. F. J. Rogers, while in the amateur classes for nine vases and six vases, Mrs. H. E. Dunhill and Mr. E. Smith secured the premier awards. Mr. C. Reid was placed first in the popular class for six vases with nine sprays in each vase.

The Reading and District Gardeners' Mutual Improvement Association secured the special Challenge Shield in the competition of affiliated Societies, with a grand set of twelve vases, the best blooms being of Sunkist, Glorious, Pinkie and Constance Hinton.

The various classes for decorations, open to lady members only, as usual proved an attractive feature of the exhibition, many very charming arrangements being displayed.

Naturally, the class requiring the decoration of a dinner table with Sweet Peas attracted the largest number of competitors, and the exhibit by Mrs. H. A. King, 14, Bunyan Road, Kempston, was deservedly awarded the first prize, for she used grand blooms of Powerscourt and Royal Sovereign in association with Maidenhair Fern to produce a very charming and delicate effect. Miss Gladys Burt was awarded the second prize, and Mrs. Moore the third.

Mrs. H. A. King also exhibited the most attractive vase of Sweet Peas, while the best basket, and that an exceedingly attractive one, was also arranged by Mrs. King, the second and third prizes being awarded to Miss Mavis Burt and Miss Gladys Burt, respectively.

NON-COMPETITIVE.

Although these were not numerous, they were of grand appearance, and added greatly to the general effect of the exhibition. At the far end of the hall, and completely filling it, was a magnificent display by Messrs. Sutton and Sons, in the form of a huge bank of large bouquets of lovely blooms, set at varying heights, and well set off with sprays of Asparagus and Maidenhair Fern, with graceful Palms in the background. Flamingo and Mammoth caught the eye at once by reason of their vivid colouring, while Blue Bird, and the pure white Avalanche; Gold Crest, Colorado, a good salmon; Majestic Cream, Powerscourt, Mrs. Horace Wright, Prince of Orange, Magnet, Valetto and Miss California, with many other charming sorts of delicate colouring, combined to complete a picture both charming and striking in its arrangement (Large Gold Medal).

Completely filling one-third of the wall on the left side was an enormous bank of Sweet Peas as set up by Messrs. Dobbie and Co., Ltd., in the form of huge sheaves of grand blooms of many choice sorts, with large bowls of flowers in the foreground. Gold Crest, Royal Sovereign and Powerscourt were shown in perfect condition, as also were Olympia, Carnival, Daffodil Improved, a really good cream; Idyl, Gleneagles, mauve-lavender; Youth, white, shaded pink; Clarion, mauve, with a plum sheen, very striking, and Mrs. A. Searles. Other good sorts in this grand exhibit were Prince of Orange, Constance Hinton, Model, Charm and Reflection (Gold Medal).

The Southfields Nurseries staged an attractive group of grand bloom,s their most prominent varieties being White Enchantress, Michel, Austin Frederick, and Youth (Silver Medal), while charming florists displays were arranged by Messrs. Robert' Green, Ltd. (Silver-gilt Medal).

Novelty Trials.

The N. S. P. S. Floral Committee attended at Birdbrook on Tuesday, June 25 to inspect the Society's Novelty Trials. All the members were present:— Messrs. D. Allan, G. F. Burt, E. H. Christy, C. H. Curtis, F. J. Rogers, F. L. Randall, C. H. Rundle, J. Stevenson and Fred J. Wheler, with Mr. Robt. Bolton, the Trials Superintendent and Mr. A. C. Bartlett, Secretary. Mr. C. H. Curtis was appointed Chairman.

Several hours were spent among the 111 trials and every entry was checked for "trueness" while certain varieties were chosen for further consideration in the stronger light of the following morning. About thirty varieties were thus selected, but on the following day very few of these were voted upon.

In the final result, Flaming June (raised by Messrs. Ireland and Hitchcock, and now the property of Messrs. Jas. Carter and Co.), was found to be true and as it was reserved for the Gold Medal in 1928 the high award was now confirmed. No. 14, a clear, cool, light salmon variety, upstanding and non-burning, was unanimously awarded a First-Class Certificate; this, as yet unnamed, was raised by Messrs. Robert Bolton and Son; it was reserved for the Gold Medal of 1930. No. 40, cream ground flushed with rosy-pink (Messrs. E. W. King and Co.), and No. 104, deep mahogany-red, from the same firm, each received an Award of Merit. These were the only awards, therefore the Floral Committee could not be accused of excessive liberality.

Mr. and Mrs. R. Bolton entertained the Floral Committee to dinner on Tuesday, and on Wednesday, when a large number of members came down to see the trials, they royally entertained the party to luncheon and tea. The President, Mr. Harold Beale, and Mr. Curtis expressed the thanks of the Society and of the members present for the creditable manner in which Mr. R. Bolton and his son, Mr. Tom Bolton, had conducted the trials, and for the charming hospitality offered to all by Mr. and Mrs. Bolton. Both the Trials and the Outing were a great success.

FRENCH NATIONAL ACCLIMATISATION.

On June 4 was held the annual luncheon of the French National Acclimatisation Society, in the restaurant of the Gare de Lyon, in Paris, under the Presidency of M. Pierre Benoit, the well-known French writer.

These luncheons, at which are wont to gather a number of well-known colonial and scientific men are famous for the number and variety of the foreign dishes provided, prepared with all the mastery of his art possessed by that excellent chef, M. Saint-Etienne.

It may be of interest to mention those among the dishes served which are of a vegetable nature:—*Saucisson Chinois* is composed of pork with Soya Bean cheese (Soya hispida), flavoured with alcoholic essence of Roses. *Moqueca à la Bahiana* is ragout of fish seasoned with Palm oil (Elaeis guineensis). *Went Ethiopien* consists of beef served with a sauce composed of various condiments including Berberi (Capsicum annuum), white Onions, Abech (Trigonella foenum-graecum), Pasobela, a small aromatic plant; white and black Azmud (Nigella sativa); Coriander (Coriandrum sativum); Ginger (Zingiber officinalis); Toségu, a creeping odoriferous plant; Gomenzer, a kind of Mustard; Cloves (Caryophyllus aromaticus), etc., etc. This dish was particularly appreciated. Wild mutton served with sweet Potatos (Batatas edulis), and, by way of Spinach, Torrent Grass (Podostemum minutifolium), an aquatic plant with long, ribbon-like leaves which is found in the streams of Madagascar. *Viandes intra-saucées* consist of meat prepared in the special way devised by Dr. Gaudichaud. A special mixture of oil, garlic or Shallot, Onion, Tarragon and spices or aromatic flavourings is injected into the veins or arteries of the meat about twelve hours before cooking, which renders it particularly tasty. (See *Revue d'Histoire Naturelle Appliquée*, Paris, 1927 and 1928).

Among other more or less unusual dishes of vegetable origin which figured at previous luncheons we may mention *gauffrettes à la Cola* (Cola acuminata), Spinach of Amaranth, Goosefoot (Chenopodium amaranticolor), Siamese Pumpkin (Cucurbita ficifolia) as Cauliflower; a *Gofio* preparation with roasted Maize; Salicorne (Salicorne sp.) as Haricots Verts; Bolets de Russie; Maté (Ilex paraguayensis); Haricots du Chili; stewed Papayas (Carica Papaya); Guava jelly (Psidium), etc.

In 1911, a whole series of dishes were prepared of Soya (Soya hispida), and in 1919 the luncheon was entirely dedicated to Rice. *A. M.*

Obituary.

Henry Ballantine, V.M.H.— This fine old gardener who had reached the advanced age of ninety-five years, passed to his rest on June 27. Mr. Ballantine was born in 1833 and began his gardening career in Scotland, but while still a young man he was appointed gardener and bailiff to the late Baron Schröder, at The Dell, Englefield Green, Surrey. Here he remained for nearly half-a-century, and on his retirement in 1911 he continued to live in Egham, where he died. For a period of twenty-five years Mr. Ballantine was a member of the Royal Horticultural Society's Orchid Committee, and in 1907 he was awarded the Victoria Medal of Honour in Horticulture. As a clever gardener and skilful cultivator of Orchids Mr. Ballantine won a great reputation and the high esteem of his employer, who, on his death, left his old servant a legacy of £1,000. In our issue of October 6, 1917, we published the portraits of Mr. H. Ballantine, Mr. T. Robinson, gardener at Cooper's Hall; Mr. J. Jemmett, of Milton Park; and Mr. A Sinclair, formerly of Hunsden House Gardens, Ware. These veterans were photographed in a group at Mr. Ballantine's home, Westwood, Egham Hill, and the combined ages of the four come to 336 years.

Felix Sohie.—We very greatly regret to learn of the death at Brussels, on June 22, at the advanced age of eighty-eight, of M. Félix Sohie, the eldest and last of the valiant little band of three brothers who established, in 1866, the Grape-growing industry at Hoeylaert, Belgium, which has now attained to such immense dimensions. Although he had lived in retirement for some time, M. Sohie was still looked upon as a "grand old man" of Belgium horticulture, and was greatly esteemed and admired not only in Hoeylaert, his native village, but in the world of horticulture generally. He was an officer of the Order of Leopold, and had also been awarded the Civic Cross of the First Class. The funeral took place at Hoeylaert on Wednesday, June 26, and was attended by a large and distinguished company of friends and relatives; his son, M. Ernest Sohie, was the chief mourner. M. H. van Orshoven represented the Minister of Agriculture, and the discourse was pronounced by M. Honnorez, the Burgomaster, after which several other friends also spoke. Hoeylaert is not likely soon to forget the founder of its present prosperity, and the immense concourse of people at the graveside, and the pile of floral tributes under which the coffin was literally buried, testified to the gratitude and esteem in which he was, and ever will be, held. Some particulars of the industry established by the Sohie Brothers will be found in our issue of May 25, 1929, p. 373.

George Todd.—For the second time in a few weeks Messrs. Daniels Bros., Ltd., Norwich, have to record the sudden loss by death of a valued employee. Mr. George Todd, whose father was a highly respected gardener in the Midlands, came to the firm twenty-three years ago, and during the past few years had been in charge of the work in connection with the staging of exhibits, for which he had a special aptitude. The groups he staged at Southport, Shrewsbury and many of the provincial Shows, were examples of his high skill. He will be greatly missed by his friends in the Trade, by whom he was held in high regard on account of his quiet, unassuming, but very charming nature. Mr. Todd was also, up to the time of his death, the Secretary of the East Anglian Horticultural Club, the premier Gardeners' Club of East Anglia. He was called away at the early age of fifty years, leaving a wife and two children to whom we are sure the sympathy of a very large number of friends will be extended.

TRADE NOTE.

We learn that Messrs. Dennis Bros., Ltd., of Guildford, Surrey, will be exhibiting their well-known motor lawn mowers, in association with motor vans, fire engines, etc., at the Royal Show, Harrogate, on July 9 to 13.

ANSWERS TO CORRESPONDENTS.

Gardener's Notice on a Sunday.—*W. A. S.* If due notice has been given in accordance with the terms of the employment, the fact of the notice being given on a Sunday does not affect its validity.

Gooseberry Fruits and Foliage Diseased.—*J. C.* The Gooseberry fruits and foliage you sent us were infected with Gooseberry rust, due to Puccinia Pringsheimiana. Pick off all infected fruits and leaves and burn them, and spray the bushes with potassium sulphide (liver of sulphur) and soap wash. Various Sedges provide the alternate host of the fungus, so that these plants should be kept down where practicable in the neighbourhood of Gooseberry plantations.

Names of Plants.—*W. A. D.* Bilbergia nutans.—*A. R.* 1, Sedum Acre; 2, Viburnum Opulus var. sterile (Snowball Tree).—*H. T. M.* 1, Gypsophila prostrata var. rosea; 2, Lithospermum prostratum; 3, Linaria origanifolia; 4, Achillea umbellata; 5, Aethionema pulchellum; 6, Veronica prostrata; 7, Campanula garganica; 8, Arenaria montana; 9, Hemerocallis aurantiaca.—G. 1, Cotoneaster buxifolia; 2, Clematis (one of the numerous garden hybrids); 3, Alyssum argenteum; 4, Philadelphus coronarius; 5, Allium Moly; 6, Arctotis, probably A. acaulis, but cannot name without complete material; 7, Dianthus, material too scrappy for identification; 8, Lathyrus rotundifolius (?); 9, Spiraea sp., material too scrappy for identification; 10, Inula glandulosa; 11, Leptospermum scoparium; 12, Cotyledon secunda var. glauca; 13, Jasminum revolutum; 14, Photinia villosa.

Number of Fruits on Egg Plants.—*C.* As your Egg Plants are now in ten-inch pots and healthy, a well-grown plant of Long Purple variety should carry six or eight fruits, but to obtain fine, well developed fruits, the number should be reduced on each plant in proportion to its strength. New York Purple, a much larger-fruited variety, seldom matures more than two fruits. The plants will not make much surplus growth if the fruits set well. It is, however, a good plan to pinch out the points of the shoots towards the end of the summer, and the plants should be fed well after the fruits have set to bring out their best qualities.

Onions Infested with Eelworm.—*C. S.* and *C.* The Onion plants were heavily infested with the stem eelworm, Tylenchus dipsaci, while a few of the plants contained larvae of the Onion fly. The control of eelworms in the field is exceedingly difficult. Rotation of crops is essential, and neither Onions nor Narcissi should be grown on infected land for at least five years. Two or three applications of nitrate of soda, applied at intervals of ten to fourteen days, might enable some of the plants to grow away from the attack. Plants killed by this pest should not be allowed to rot in the ground or on the rubbish heap, but should be burnt.

Vine Foliage Unhealthy.—*C. W.* The vine foliage is free from attack by pathogenic organisms. The leaf exhibits a chlorotic condition, which is probably due to overshadowing by other leaves so that light is cut off. A somewhat similar condition results from an excess of lime in the borders. The amount of water draining from the pots on the shelf is probably insufficient to have any deleterious effect on the vines.

Yew and Box Hedges in Poor Soil over Chalk.—*W. G. B.* That both Yew and Box will flourish on poor, chalky soil is amply demonstrated by the way they both grow on the chalk hills of Surrey and elsewhere, therefore we see no reason why your scheme should not meet with success. If the soil can be enriched somewhat, so much the better, and next season mulching will probably have to be done to assist root development.

Abstract Published.

One of the latest products of the famous British firm, the Imperial Chemical Industries, is a chemical manure patented under No. 309,299. A fertiliser consisting of ammonium nitrate and calcium carbonate, obtained as a bye-product in the preparation of ammonium sulphate from ammonium carbonate and calcium sulphate, with or without other ingredients, as described in Specification 305,760, is, according to the present invention obtained by spraying or atomizing a hot concentrated solution of ammonium nitrate mixed with the calcium carbonate, preferably down a tower, in contact with a stream of air. Granules of the mixed salt collect at the base of the tower and are dried and sifted to separate fines. The preferred method of spraying is to disintegrate an annular stream of the slurry by means of jets of heated air.

Remarks.—Supplies generally throughout this department have been on the increase and, with the exception of Lilium longiflorum, prices have been on the down grade. Carnations have been sufficient to meet present requirements, although prices have been from 1s. to 4s. per dozen, and best grade blooms have been cleared before the market closed; similar conditions exist with Roses, but owing to colder conditions supplies were somewhat shorter this morning; good red and yellow blooms were soon cleared. Spanish Irises will probably finish this week. Arrivals include Lilium speciosum var. album, a few white Asters from France, Clarkias, Godetias, and white and pink Saponaria. All other subjects are similar to last week's quotations, and business generally has not been so brisk.

Remarks.—Trade in the fruit market is moderately brisk and even Strawberries have not materially affected other sections as they usually do. Peaches, Nectarines, Figs, Melons and Grapes are selling with some freedom, although prices are a shade easier than last week. Strawberries, chiefly from the Southampton district, have fluctuated in both demand and supply, and prices have been variable. Some good English Cherries are now arriving, but quantities are not large. Gooseberries are a weak market and only first-grade fruits are saleable at fair prices. Plums and Apricots from Spain are plentiful and receive a fairly good reception by buyers. Tomatos sell at slightly lower rates, although still rather higher than at this time last year. Cucumbers have been a firmer market during the last few days. French Beans continue to sell well. Peas are comparatively low in price and new Potatos remain a weak market. Some good Cauliflowers have met a ready sale and good Cabbages sell well at prices that are not particularly low. Mushrooms have recovered to a better price level and salads, especially Lettuces, are very cheap.

GLASGOW.

While there was no important change in prices in cut flowers last week, the tendency was slightly easier in certain sections. Scottish Irises sold at from 3d. to 6d. for 6's, and English Irises 10d. to 1s. for 12's; Gypsophila was plentiful and cheap at 1d. to 3d. per bunch; while Anemones realised 1d. to 2d.; Pyrethrums, 1d. to 3d.; Paeonies, 6d. for 3's; Lilium longiflorum, 1s. 6d. to 1s. 9d.; Lily of the Valley, 1s. 8d. to 2s. 6d.; Carnations, 1s. 6d. to 3s. per doz.; Roses, 2s. 6d. to 3s. 6d.; Sweet Peas, 2d. to 10d. per bunch; special, 1s. to 1s. 3d.; Gladioli, large, 1s. to 1s. 6d. per 6's; small-flowered, 6d. to 10d.; Poppies, 6d.; Nigella, 8d.; Lupins, 3d.; Cornflowers, 2½d.; and Asparagus, 9d. to 1s. 6d. per bunch.

In the fruit market English Black Currants sold at 1s. per lb.; French, 12s. (20 lbs.); Strawberries, 8d. to 1s.; Cherries, 4s. (6 lbs.); Peaches, 10d. to 1s. 3d.; Plums, 9s. to 10s. per sieve; Melons, 3s. 6d. to 5s. each; Apricots, 10s. 6d.; Pineapples, 3s. 6d. to 4s.; home-grown Grapes, 2s. 9d. to 3s. per lb; Grapefruits, 28s. to 40s. per case; Winter Nelis Pears, 7s.; New Zealand Apples, 17s. to 20s. per case; and Oranges, 25s. to 35s. Gooseberries were abundant and realised 2d. to 3d. per lb.

Tomatos declined in price to 7d. to 10d. per lb. for Scotch and 5d. to 6d. for Guernsey. Scotch Cucumbers were worth 5s. to 6s. per doz.; Lettuces, 1s. to 1s. 6d.; Beans, 1s. 4d. per lb.; Radishes, 1s. 6d.; Syboes, 3d. to 4d.; Mint, 3d.; Carrots and Turnips, 10d. to 1s. 1d.; Mushrooms, 1s. 6d. to 2s. per lb.: and Rhubarb, 3s. per cwt. Supplies of Peas exceeded the demand and were sold at prices so low as 7s. for 40 lbs.

TO ADVERTISE ONCE ONLY, IS TO INVITE FAILURE; TO ADVERTISE ALL THE YEAR ROUND IS TO ENSURE SUCCESS.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 63·2°.

ACTUAL TEMPERATURE—
The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London, Wednesday, July 10, 10 a.m. (Greenwich time). Bar. 30. Temp. 66°. Weather, fine.

The "Early Bite."

MANY gardeners are interested in grazing and all are interested in grass, and therefore it will not be without interest to comment upon the announcement made at the opening of the new Agricultural Research Station of Imperial Chemical Industries, Ltd., at Jealott's Hill, on a subject somewhat cryptically described as the "early bite." Gardeners who are accustomed to observe the gradual awakening of plants in spring may have formed hypotheses as to the nature of the awakening process. They probably have concluded that even before the season is propitious, plants are ready to awaken and begin to grow, but that their will to grow is held in check by unsuitable conditions of temperature. Broadly speaking, that is no doubt true. Unless temperature be congenial, growth will not take place. But broad generalisations are only true in a broad way, and this one is no exception. In addition to what may be called the major limiting factor, there may be other subsidiary limiting factors; for instance, in the case about to be considered it is now known that when temperature is propitious or at all events adequate for some growth, the growth of grass may be extremely dilatory owing to the fact that all supplies of nitrogen have disappeared from the soil during the winter. That being the case, it follows that if those supplies are obtained, spring growth will begin. Experiments made over very wide areas under different conditions in England, Scotland and Ireland show that this is true. If after a suitable basal dressing of phosphate and potash has been applied in late winter or early spring, it is followed by a suitable nitrogen fertiliser in February or March, then vigorous growth begins some three or even more weeks earlier than on corresponding pastures which have not been treated in this manner. Needless to say, growth may only take place when the rigours of winter are past and when sufficient moisture is contained in the ground but, as everybody knows, grass is an opportunist and will develop under any conditions which make growth possible. One of these conditions we now know is a ready and available supply of soluble nitrates. The natural pasture, after a winter has depleted the soil, contains too little available nitrogen for more than painfully slow growth, hence the marked quickening after an application of a nitrogen fertiliser in the early part of the year. The advantage to the agriculturist of this fact is evident, and gardeners also may make use of it when their lawns have been adversely affected either by summer drought or a previous hard winter. It is of interest to remark that each of the three chief fertilisers, nitrogenous, phosphatic and potassic, seem to exert a special influence on the time of maturing of crops. Nitrogen hastens leafy growth and so provides "early bite." Phosphates quicken the formation of grain—so much so that it is plain in parts of Canada that a dressing of phosphates may make the grain ripen sufficiently early to escape the clutches of early winter. Potash again, by conferring resistance against cold, may enable the crop to live through and maintain itself during winter weather. These seasonal influences of fertilisers, which are beginning now to be understood, are clearly destined to prove of importance, not only to the farmer, but also to the gardener.

The Hardy Fruit Crops of 1929.—In accordance with our usual custom, we have invited numerous gardener-friends to report upon the amount and condition of the hardy fruit crops in their districts, with the request that the reports be returned to us without delay. We shall be pleased to send forms to any fruit-growing readers who would like to send us reports of the conditions ruling in their areas.

The Rose Dell at Kew.—The rambling and climbing varieties of Roses in the Rose Dell, near the Pagoda, at Kew, are very attractive at the present time; varieties which are not self-supporting are trained to large or small assemblages of rustic poles, according to the size of the group, and height of the variety. The climbing and rambling type of Rose has received considerable attention from the hybridist during recent years, and by crossing and intercrossing the old rambler type of Rose with the Hybrid Teas, quite a useful and attractive break has been secured. While retaining the tall, free growth of the ramblers, the hybrids have a considerably extended period of flowering, and the blooms more resemble those of Hybrid Teas. A few of the most distinct and useful varieties flowering at Kew are Purity, a beautiful snow-white, free in growth and with luxuriant foliage; Paul's Scarlet Climber, an attractive scarlet-red sort, the blooms lasting in good condition longer than most varieties; Albertine, coppery-salmon, very beautiful in bud; Dr. van Fleet, soft blush-pink; Mary Wallace, rosy-pink shaded salmon; Chastity, another good white; Miss Helyett, a strong-growing Rose with carmine-pink blooms; and Jacotte, coppery-salmon, shaded yellow, with attractive, shining foliage. Particularly effective are a number of very vigorous white sorts; Rosa moschata, thirty feet or more in height, trailing through Holly branches; Madame d'Arblay, over a rustic arch; several large groups of the single white variety Silver Moon, and imposing masses of Seagull. The Hybrid Musk Roses are most effectively represented by Vanity, rosy-pink; Pax, white; Danae, yellow; Moonlight, lemon-white; and Nur Mahal, cramoise; Alberic Barbier, creamy-white; and Mrs. F. W. Flight, pink, are also of outstanding merit.

Antwerp International Horticultural Exhibition, 1930.—The work of preparation for the International Horticultural Exhibition, to be held at Antwerp during the spring and summer of next year, in connection with the World's Fair and other events in celebration of the Centenary of Belgian Independence, is proceeding apace, and the preliminary preparation of the ground for the open-air horticultural exhibits is completed. Those intending to exhibit plants and trees can now, by making previous arrangements, pay a visit to the site; this is of considerable advantage, as it enables exhibitors to judge of the amount and kind of material required, and of the effect likely to be produced in conjunction with the natural surroundings. Information of all kinds can be obtained from the Secretary, Antwerp Royal Horticultural Society, Rue de Péage, 10, Antwerp; or from the Secretary, Section Agricole et Horticole, Canal des Récolets, 17, Antwerp. There is no doubt that the exhibition will be on a very large scale, and that the Centenary festivities and the World's Fair will bring a concourse of wealthy and important visitors to the city.

An Orchid Hospital.—We are informed that a "hospital" for sick Orchids has been formed by Mr. W. B. Berger, a Colorado grower, who has equipped a section of his glasshouse with vita glass as a "ward" where delicate plants may become convalescent under the sun's natural ultra-violet rays. Not only has Mr. Berger not lost one plant grown from poor material this season, but he has promoted new growth in his hospital on plants supposed to be dying. A Moose-Antler Fern has also recovered under the natural ultra-violet rays, and a Rubber plant brought in practically dead with only one leaf is reported to be "exceedingly hearty" after a few months' treatment.

Presentation to Mr. Arthur Bedford.—Our readers are well aware that Mr. Arthur Bedford is the able gardener in charge of the extensive gardens and plant collections belonging to Lionel de Rothschild, Esq., at Exbury, Southampton, but not all are aware that for twenty-one years he has been a member of Committee and, latterly, Treasurer of the United Horticultural Benefit and Provident Society. The Officers and Committee of this useful and successful society, and the members, have not, however, overlooked his "coming of age," and on Monday, July 8, they showed their appreciation of his long services. Mr. and Mrs. Bedford were entertained to dinner by the members of Committee and a few friends, in London, and on behalf of the Society, Mr. Charles H. Curtis, who presided, presented Mr. Bedford with a handsome and suitably engraved gold watch, and Mrs. Bedford with a gold wristlet watch. There were about fifty friends present, and a very delightful evening was spent, as several of the visitors proved to be first-class musicians and entertainers.

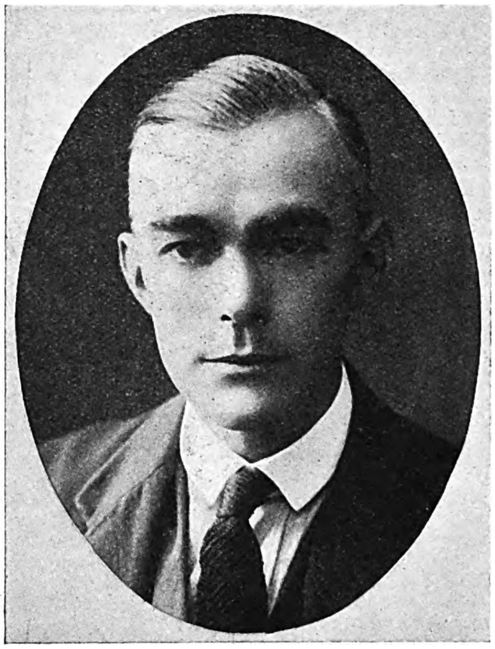
New Sports Ground and Pavilion at Wisley.—On Saturday, June 29, on the occasion of the visit of the Vincent Square Staff of the Royal Horticultural Society to the Society's Gardens at Wisley, a twelve-a-side cricket match was played between teams representing the London Staff and the Gardens Staff and Students. This was to commemorate the opening of the new sports ground and pavilion, given by the R.H.S. Council. The opening ceremony was performed, in the absence of the President, Mr. G. W. E. Loder, by Mr. W. R. Oldham, J.P. Mr. Oldham was in a dilemma; being Chairman of the Gardens Committee, he hoped Wisley would win, but being a member of the Council, he backed the Londoners. It is hoped, however, that he was satisfied with the result. The weather was glorious, and the game was witnessed by an enthusiastic crowd, representative of both departments. Wisley won the toss and batted first, but were all out for eighty-four, of which A. N. Rawes contributed a bright thirty-nine; Reynolds was responsible for some good bowling in taking seven wickets for twenty-nine. The visitors started none too well and six wickets were down for twenty-four, before Streeter and Douglas came together. Things now began to brighten considerably, and forty-six runs were added before Streeter was bowled for thirty-one. Douglas brought the score to within one run of the Wisley total before being run out for a hard-hit twenty-eight. With three wickets still to fall, two runs only were required for victory. Amid great excitement two more wickets fell without further addition. With the last man in a single was snatched; but the next ball gave relief to many pent-up feelings, and an excellent game ended in the extraordinary, but highly satisfactory result of a tie!

Horticulture in Jamaica.—Although the greater part of the space is devoted to agricultural matters, the *Annual Report* of the Department of Agriculture, Jamaica, for 1928, contains much that is of interest to horticulturists. The frontispiece to the *Report* consists of two reproductions depicting the Orchid Houses at Hope Gardens, wherein, as explained in the text, a collection of Orchids is grown, representing thirty different genera; recent additions include one hundred plants each of Cattleya Mossiae and C. Luddemanniana from Caracas, and twenty choice varieties of Brasso-Cattleyas and Brasso-Laelio-Cattleyas obtained from Messrs. H. G. Alexander, Ltd., Westonbirt, Tetbury. Cannas appear to be grown extensively in the Hope and the Kingston Gardens, but diseases and pests are causing some trouble in their cultivation. A new Plant House, sixty feet by fifteen feet, has been erected for the public display of Orchids in flower. Plants distributed free from the Hope Gardens numbered 345,270 during the year, while 120,738 plants, chiefly of economic subjects, were sold to planters. At the Castleton, Kingston Hill, King's House and Bath Gardens, good work continues in the planting and development of both ornamental and economic plants, and regrets are expressed that in the construction of certain roads some fine examples of Poinciana regia, Cassia fistula, Casuarina equisetifolia and certain Palms had to be destroyed. It is of homely interest to learn that at the Hill Garden "a good number of Pines and other suitable trees are supplied to meet the demand for Christmas Trees." The rainfall record is curious and, doubtless, governed by altitude, but there is a wide difference between the 24·85 inches at King's House Garden and the 107·42 at Castleton.

Legacies to Gardeners.—The late Mr. Montague Richard Waldo-Sibthorp, of Canwick Hall, Lincoln, who died on March 19, left £100 to his gardener, Mr. George Green.—The late Mr. Robert Henry Benson, of Buckhurst, Withyham, who died on April 7, left an annuity of £150 to his gardener, Mr. John D. Philpott, and his wife.—The late Mr. William John Worthington, of Rotherwood, Higher Bebington, left £100 to his gardener Mr. Thomas Gittins.—The late Mr. Alfred Hood, of Strathalyn, Rossett, Denbighshire, left £100 to his gardener, Mr. Benjamin James Guy, if still in his service and not under notice.—The late Sir Sidney Byass, Bart., of Llandough Castle, Cowbridge, Glam., left £200 to his head gardener, Mr. R. German, £120 to Mr. J. Evans, £130 to Mr. E. Humphrey and £50 to Mr. J. Jenkins, under-gardeners.

Ormskirk Potato Trials, 1929.—The National Institute of Agricultural Botany extends an invitation to parties of farmers, Potato growers and merchants, and agricultural advisory and administrative officers to visit the Potato Testing Station, Ormskirk, singly or in parties, on August 8, 1929, or if this date is inconvenient, on any week-day between July 29 and August 10. Besides the usual trials of new varieties of Potatos for immunity from Wart Disease the Institute is continuing for the Ministry of Agriculture and Fisheries investigations into the relative resistance of a number of varieties to Leaf-roll, and the possibility of growing in England seed Potatos free from virus diseases. These trials will be open to the inspection of visitors. In addition, visitors will be able to see the Lord Derby Gold Medal Trials—of which there are three separate trials this year—and Yield and Maturity Trials of the leading early and main crop Potatos. There is also a large number of demonstration plots of British and foreign varieties of Potatos, including those certified as immune in 1927 and 1928, and an interesting series of plots of some common Potato synonyms. Secretaries of branches of the National Farmers' Union and others wishing to organise parties to see the trials should write to the Superintendent of Potato Trials, Potato Testing Station, Lathom, Ormskirk, Lancashire, suggesting alternative dates. Individual visitors will be equally welcome, but they, too, should inform the Superintendent of the date of their visit not less than a week in advance. Ormskirk is conveniently reached by a frequent service of local trains from either Liverpool or Preston.

Mr. G. H. Nash, N.D.H.—Mr. G. H. Nash, who has been appointed Horticultural Organiser to the Warwickshire Education Committee, in succession to Mr. H. Dunkin, who has retired, is a native of Surrey, and served his apprenticeship at Selsdon Park, near Croydon. He also served in the gardens at Headley Park, Epsom, and Fetcham Park, Leatherhead. In 1914, he enlisted in the Coldstream Guards, and was later commissioned to the Royal West Surrey Regiment. He was demobilised from the Army with captain's rank. After the armistice, he was appointed chief instructor in horticulture at the Army Science College, Bonn, Germany, and afterwards transferred to the position of Chief Horticultural Instructor at the Army General and Commercial College, at Cologne. He was demobilised in 1920, and received an appointment under the Gloucestershire Agricultural Committee at their centre at Quedgeley, near Gloucester, for the training of disabled ex-service men in commercial horticulture. That position he held for two years, next proceeding to Earl's House School, Durham, to take up an appointment as Horticultural Instructor there. Two years later he was appointed Instructor of Horticulture at the University of Leeds, which position he held until taking charge in Warwickshire on July 1. Mr. Nash received high credentials from the University authorities, and left with the heartiest good wishes of his colleagues. In taking up his duties at Warwick, there is every reason to anticipate that he is entering up on a new sphere of activity in which his abilities will be displayed to advantage.



MR. G. H. NASH, N.D.H.

Government Dinner to the International Professional Horticultural Federation.—On Wednesday night, July 3, the Government entertained the members of the Fédération Horticole Professionelle Internationale, who were holding their annual conference in this country. In proposing the toast of "The Guests," the Right Hon. Noel Buxton, Minister of Agriculture, said it was fitting that this International Conference should meet in London when it could be entertained by a Labour Government, because the Labour party sympathised above all with international movements. The vital thing was to increase mutual understanding between peoples, and it was a happy thing that members of the Fédération Horticole Professionelle Internationale could be pioneers of peace while concerned with such delightful subjects as plants and flowers. He had himself been indebted to the international side of gardening, having learnt from the Japanese the idea of miniature landscape and practised the art in several places. The Government stood for the free entry of foreign plants, except where it must be limited on account of disease. Horticulture was also an instrument of social welfare. He was glad to know it was becoming increasingly a democratic institution. Till lately it had been somewhat plutocratic, but he had been greatly struck by the change in the gardens of the working classes both in town and country. Cottage gardens now frequently grew Darwin Tulips, and he invited their approval of the National Gardens Guild to which Her Majesty the Queen was Patroness, which existed to encourage gardening in towns and even in slums. It was operating in mining areas and introducing cultivation even in prisons. Local authorities were beginning to encourage window boxes by supplying boxes and soil at cost price.

Dahlia Year Book.—When Mr. W. J. Chittenden died, the National Dahlia Society lost a hard-working Honorary Secretary and an excellent Editor of its Year Book. Fortunately, the mantle of his genius has fallen upon his son, Mr. W. E. Chittenden, who is building firmly on the broad foundations laid by his father. The *Dahlia Year Book* affords further evidence of the happiness of this succession for it is a useful publication, rendered attractive by the numerous illustrations, one of which is in colour; unfortunately, the portrait of Mr. J. Emberson, so long the Hon. Show Superintendent, is very poorly reproduced. Mr. T. Hay, M.V.H., who acquired the late Mr. C. Harman Payne's collection of books on the Dahlia, deals with the flower from the historical point of view, and in a way that appeals to lovers of old horticultural literature. Mr. F. G. Treseder writes of Dahlias in Wales and Mr. J. Coutts describes the usefulness of Dahlias in our great National Gardens at Kew. Mr. D. B. Crane deals with the Uses of the Dahlia as a Cut Flower, and had he visited the flower markets at Aalsmeer he would be even more enthusiastic than he is regarding the future market value of Dahlias as cut flowers. The same author describes the numerous Dahlias chosen at the R.H.S. meetings to be tried at Wisley. Greatly daring, Mr. A. Vasey, considers the future of the Dahlia, while Mr. Robert Fife deals very practically with the Cultivation of the Dahlia, and Mr. Riding's ripe experience and judgment is shown in Dahlia Novelties of 1928. The Society's exhibition is reported in detail, and there is a list of members of the Society, and other interesting matter, the whole making up a booklet useful alike to the amateur and the professional grower of Dahlias, and one that should make for an increase of membership.

Belgian Tax on Florists' Flowers.—Florists in Brussels are making vigorous protests against the new decree, promulgated on June 8, which has the effect of varying the incidence of the Luxury Tax as it affects the sale of flowers, and of still further complicating the already confusing and difficult calculations which the Belgian florist is obliged to make before he can sell the simplest floral offering or bouquet. The new decree has reference to plants in pots, and lays it down that the tax on pot plants of over twenty-five francs in value is to be six per cent. of the price; but that if the plant is sold in conjunction with something else, for instance, a basket or a fancy pot, the tax is to be charged on the combined price, unless the basket, etc., has already been taxed when it was purchased by the florist, in which case only the plant itself is taxed when the sale is effected. Where plants in pots and cut flowers are sold together—which can easily be the case where a presentation basket of flowers is made up—the matter is still further complicated by the fact that the cut flowers are taxed on a different scale viz., ten per cent. of the price. A strongly worded protest has been addressed by the Belgian Florists' Union to the Minister of Finance on the subject of the decree, which came into force on June 15.

Nitrogen: Synthetic and Natural.—It is officially announced that an agreement has been arrived at between the Chilean Finance Minister, Senor Pablo Ramirez, and Imperial Chemical Industries, Limited, having for its purpose closer co-operation between synthetic nitrogen and Chilean nitrate of soda, on similar lines to the agreement concluded between the Chilean Finance Minister and the I. G. Farbenindustrie A. G., which agreement is being announced concurrently. An agreement has also been concluded between Imperial Chemical Industries, Limited, and the I. G. Farbenindustrie A. G., with regard to co-operation between those two companies in the production, marketing and propaganda of synthetic nitrogen products. The agreements provide for a common policy to be pursued in the future regarding propaganda and similar matters relating to fertilisers. A substantial basis for the stabilisation of the nitrogen industry has thus been reached, and it should be noted that this stabilisation is accompanied by a substantial reduction in the prices of nitrogenous fertilisers amounting to 10s. per ton. This is a matter of great importance to the agricultural and horticultural industries of the world. Even before this latest reduction, the prices of nitrogenous fertilisers were substantially lower than they were before the war. The large nitrogen groups are, therefore, making a considerable effort to assist farmers in the present crisis through which the agricultural industry is passing. The agreement between the three largest producers of nitrogenous fertilisers in the world, outside the United States, should pave the way for a stabilisation of the nitrogen industry, inasmuch as it is proposed to invite the other national groups of nitrogen producers to come into line.

The John Melrose Agricultural Laboratory, South Australia.—Much has already been done in South Australia in the way of agricultural research and local farmers and graziers have derived marked benefits from the application of scientific methods to practical operations. Bequests by the late Mr. Peter Waite led to the establishment of the Waite Agricultural Research Institute, where, during the past four years, valuable scientific investigations have been conducted. A further gift of £10,000 by Sir John Melrose has been utilised in the erection of a chemical laboratory, in which research work will be carried on in conjunction with the Waite Institute. The John Melrose Laboratory was declared open recently by His Excellency the Governor, General the Hon. Sir Alexander Hore-Ruthven, V.C., K.C.M.G. The Premier (Hon. R. L. Butler) expressed his deep appreciation of the generosity of Sir John Melrose, whose desire to help not only South Australia, but the Commonwealth as a whole, could not have been shown in a more fitting manner. The Minister of Agriculture (Hon. John Cowan) said that the Waite Agricultural Research Institute had already proved of great value to the people of the State, and by the addition of the John Melrose Laboratory it would rank as one of the best-equipped Institutions of its kind in the world. South Australia was essentially an agricultural country, and for many years its progress and prosperity would depend chiefly on the development of the great primary industries. South Australian farmers, he was sure, would be prepared to follow the advice of the experts of the Waite Institute. If by the adoption of more scientific methods, judicious use of super-phosphates for top-dressing natural pastures, and the cultivation of subterranean Clover, production could be increased, the stock-carrying capacity of the land improved, and the bounds of settlement extended, the benefits to the State would be immeasurable.

Appointments for the Ensuing Week.—TUESDAY, JULY 16: Royal Horticultural Society's Committees meet; London and South of England Viola and Pansy Society's Exhibition; Roundhay (Leeds) Horticultural Society's Exhibition; Leeds Paxton Society's visit to Roundhay Show; Wolverhampton Floral Fête (three days). WEDNESDAY, JULY 17: Guildford and District Gardeners' Association's exhibition; Haywards Heath and Mid-Sussex Horticultural Society's Exhibition (two days); Liverpool Horticultural Association's Summer Show (two days. THURSDAY, JULY 18: British Carnation and National Carnation and Picotee Societies' Show (two days); Brentford and Chiswick Horticultural Society's Show; Birmingham Horticultural Society's Floral Fête and Exhibition (two days); Hull and East Riding Rose Society's Annual Exhibition. SATURDAY, JULY 20: Worcester Park Horticultural Society's Exhibition; Sundridge and Brasted Society's Annual Exhibition; Leeds Paxton Society's Rose Show; Alderley Edge and Wilmslow Flower Show.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Horticultural Society's Show at Chiswick.*—At twenty-five minutes to six on July 8, the Queen, accompanied by His Royal Highness Prince Albert with their Royal Highnesses the Prince of Wales, and Prince Alfred, arrived, and was received by General Fox and other members of the Council, His Grace the Duke of Devonshire, the President of the Society, being unfortunately ill. Upon entering the tents, Her Majesty was pleased to accept at the hands of General Fox, a magnificent bouquet, formed from the rarest flowers in the exhibition. The royal party then proceeded to inspect the exhibition tables, passing along the whole line, and examining the varied objects as they presented themselves. The principal exhibitors, stationed within the barriers, had the satisfaction of remarking personally what degree of interest their stands excited. The large conservatory was next visited, after which, having rested for a few minutes in the royal tent, Her Majesty walked round the Arboretum, passing the great Poplar tree transplanted in 1853 by M'Glashan's apparatus, in the presence of Prince Albert, and, visited the ground near the orchestra, where the Queen paused to listen to the military bands; at twenty minutes to seven Her Majesty returned to her carriage, having previously been pleased to express her satisfaction at the "beautiful show." And a most beautiful show it was—in every way worthy of being exhibited before the Queen. To the exhibitors themselves it must have been a day to be remembered with honest pride, for it was the first time that the Queen had visited in public any of those great horticultural exhibitions which are the summer glory of her metropolis, and on that occasion the exhibitors nobly sustained the reputation of their country for excellent gardening. *Gard. Chron., July 15, 1854.*

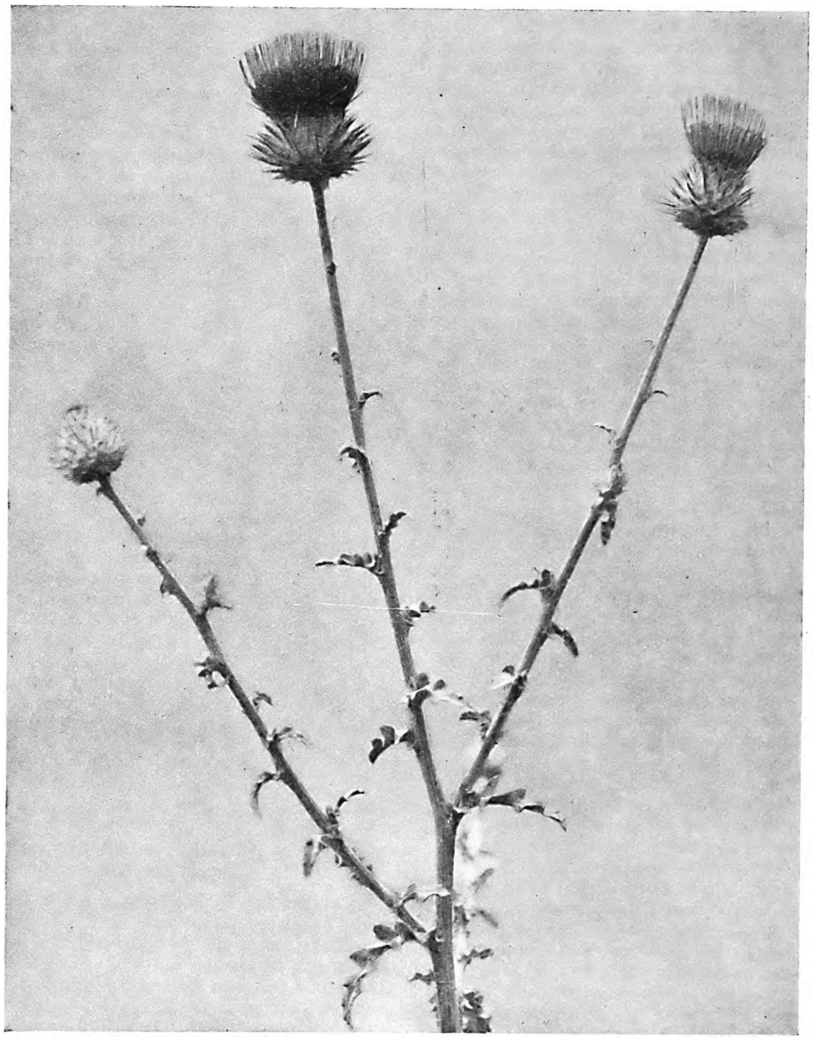


FIG. 11.—CIRCIUM OCCIDENTALE VAR. COULTERI.
(see pp. 28 and 35.)

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Manchester.

Bulbophyllums and Cirrhopetalums.—Many species of these closely allied groups produce their remarkable flowers during the spring and early summer months. When in flower these Orchids are always a source of interest, the singular structure of the blooms commanding attention, while the free-flowering qualities and attractive colouring of many of the species make them very useful and decorative Orchids. Some of them have a pleasant scent, as in B. cosmosum, but others, such as B. Ericssonii, emit a very unpleasant odour during certain parts of the day. The plants thrive well when grown in pans or baskets suspended from the roof of a warm house. During the growing season they require ample moisture both at the roots and in the atmosphere, although saturation should be avoided. Shade the plants from strong direct sunshine. Many of the Cirrhopetalums require planty of light to induce the plants to flower freely after the growth is complete. During the winter when less water is naturally required, the plants should not be subjected to long periods of drought, and enough water should then be given to prevent the pseudo-bulbs shrivelling. At this season new roots are being produced freely, and any plants requiring fresh rooting material should be attended to forthwith. It is not advisable to disturb the roots unless the plants have overgrown their receptacles and require dividing up or potting on. In such cases the old compost and decayed roots and growths should be removed carefully, severing the rhizome between the third and fourth pseudo-bulb. Some of the species are of a rambling nature and may be made more compact with the aid of a few wire pegs, taking care not to twist the rhizomes too sharply, and keeping the bases of the pseudo-bulbs about level with the pot rim. Pot them moderately firmly, using a compost of three parts A.1. and Osmunda fibre, and one part Sphagnum-moss, adding crushed crocks as the work proceeds, to keep the compost porous. Plants that are not in need of fresh receptacles should have the old and sour portions of the soil removed, disturbing the live roots as little as possible, and fresh compost carefully and firmly worked among the roots, finishing the surface off with a little extra Sphagnum-moss. Water should be provided sparingly until the roots are well-established in the fresh soil. Small-growing sorts such as Bulbophyllum barbigerum and Cirrhopetalum miniatum, should be grown in very little compost and accommodated in small receptacles or on blocks of wood. Spray the plants occasionally with a weak solution of a safe insecticide to keep thrips, etc., in check. Small scale insects should be removed so soon as detected.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Budding Fruit Trees.—The propagation of fruit trees by budding has proved to be so advantageous that it is now the most common method of increasing nearly all kinds of fruits. To be successful, however, it is essential that the sap should be in full flow, and that both the bud and the stock should be in the right condition, which means that they should be sufficiently matured to cause little or no trouble in removing the bud, or in raising the bark upon the stock. If the stock is in a suitable condition, the bark will lift away without any forcing, which would bruise and otherwise injure the soft tissues lying between the bark and wood; the same applies to the bud. Cherries are about the first to be ready, and they are followed by the Plum and the Pear, and later, the Apple. Owing to the very dry season, the growth on most trees is well matured and the buds well advanced. In the case of the Cherry the buds take more readily when they are not too plump. Indeed, the same may be stated of all fruit trees. With the exception of Peaches and Nectarines, most hardy fruit trees are "worked" close to the soil, and, if standards are desired, the stems are "run up" to the necessary height. Cherries are commonly worked at the desired height, *i.e.*, half-standard or standard, but a standard stem is made more quickly when the stock is budded at the soil level. Budding is best performed in dull weather, and should the bark not lift readily, water the soil well about the stocks and delay the operation for a few days. Do not trim off any superfluous growths immediately before budding, or the flow of sap may be checked. When cutting a shoot for buds, remove all the leafage, with the exception of half-an-inch or so of the petioles, which will prove advantageous as handles with which to work the bud into position later. Place the shoots in water at once. Shoots of medium size produce the best buds. When starting operations, the bud should be "taken" first, as any incision on the stock should not be unduly exposed. The bud is removed by making a slicing, shield-shaped cut with a sharp knife, commencing less than an inch below the bud and gradually going deeper as the blade passes under the bud. Then with a slight lift of the blade, break off the bud with a strip of the bark attached. By bending this strip back a little, the bark will part from the small piece of wood still covering the seat of the bud. Remove this portion of wood by a gentle pull. If the bud is in a suitable condition the seat or heel of it will be well exposed. This will ensure its resting well down upon the wood of the stock, and unless this seat is well developed, it is not much use inserting the bud, and another should be tried. On the stock make a long, T-shaped cut close to the soil level, gently lift the two flaps of bark and slip the prepared bud under and push it well down. Avoid any bruising or forcing in of the bud. The upper end of the shield should be cut square so that it fits exactly with the cross cut on the stock. Tie the bud in firmly, either with Raffia, or coarse strands of worsted. It is essential that the tie should be made firm just behind the bud to ensure the seat or heel fitting close down upon the wood, but at the same time no undue constriction should be employed.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Strawberries.—Good runners are rather later in developing than usual, and the young plants should be watered regularly if the weather is dry, and in two or three weeks they will be ready to sever from the parent plants; it is at this stage that care is necessary to obtain the most satisfactory results. The great point is to get a good start and keep it. The runners should be layered so soon as ready, and should not be kept in the small pots for more than four weeks. Repot them into five- or six-inch pots, in a compost of good fibrous loam, with a little old Mushroom-bed manure, lime-rubble and bone-meal added. Use clean pots and crocks and apply a sprinkling of soot over the latter; pot the plants firmly and then stand them on a hard, solid bottom of ashes, thick enough to prevent worms from coming through it. Place them in an open space in full sun, far enough apart for the air to circulate freely among them. With such treatment the plants will make a mass of roots before the end of the season. They will need liberal supplies of water. Much depends on the quality of the compost as to whether manure water will be needed at this stage; if the soil becomes exhausted, a little help with fertilisers will enable the crowns to plump up properly. Growth should be completed by the end of October; by that time the plants ought to have formed good, solid crowns, and they should be rested during November and December, especially the early varieties, but should not be allowed to get too dry at the roots.

Cherries.—The crop of early Cherries will now be finished. All trees which do not require repotting may be turned out, well cleansed and plunged in the open air for the remainder of the summer. Choose a light, airy, but sheltered position, and if the pots are well filled with roots the plants should be well mulched with decayed manure to feed the buds and leaves, and to economise labour in watering. Trees which require a shift may be kept under glass two or three weeks after being repotted to encourage the formation of fresh roots. Use a compost of good, rather strong loam, lime rubble, with a little bone-meal, and with or without a little old cow manure, according to the quality of the loam. The ball of roots should be thoroughly moist at the time of potting, while the compost can hardly be too dry, as it must be rammed firmly to prevent the escape of water. Very late varieties should have a light, airy section of the house to themselves, and should be protected, as, next to birds, the greatest enemy is dampness, especially when the fruits are fully ripe and outside conditions are unfavourable. Plenty of air on fine days, and possibly some light shading, is beneficial, but the latter should not be permanent.

Plums.—The growth of these trees should be kept well pinched, not only to let in light and air and to force the sap into the flower buds, but also to keep aphides in check, as it is upon the young shoots that these pests thrive and multiply. The trees should be kept in sections, according to their fruiting time, and when the earliest are cleared of fruits they may share the open quarters of the Cherries, and be afforded similar treatment. Midseason and late varieties should be top-dressed and fed regularly with warm, diluted liquid soot and guano water alternatively. Syringe the trees with soft water only, otherwise the "bloom" of the fruits will be damaged, and this should be kept perfect. These late varieties do not like hard forcing and do not require it, as the best varieties can be ripened to perfection in an ordinary, well-ventilated house.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Hemerocallis.—The Day Lilies form a useful group of free-flowering herbaceous plants at this season, and are ideal for grouping either in the herbaceous border or in the semi-wild garden. For the latter purpose they are well adapted, and few plants give more satisfaction when once established. Under such conditions their requirements are few, provided the site was well prepared before planting. They may be used with effect by the side of ponds, or may be interplanted with Ferns, where their flowers and foliage will mingle effectively with the fronds of the Ferns. The Day Lilies last fairly well as cut flowers, and are delightfully fragrant.

Budding Roses, etc.—Welcome rains have fallen and the budding of Roses may be commenced whilst the sap is flowing freely. The stocks will require a moderate amount of pruning, removing weak and superfluous growths and clearing away an inch or two of the soil around the base of the stock before commencing to bud. The selection of buds is an important factor if successful results are to be obtained. Well-ripened growths that are carrying or have had flower buds cut from them, should be selected. These shoots should be placed in damp moss or water to prevent the buds becoming shrivelled or dry before being used. Under such conditions they will keep in good condition for several days if the stocks are not ready. As the most successful results are obtained if the buds are inserted when the bark parts freely from the wood, budding should, when practicable, be done immediately after rain. Many scarce and rare shrubs may also be budded if suitable stocks are at hand and time is available for this interesting operation that is so seldom practised in private gardens.

Routine Work.—Beds of Violas and Pansies should be examined frequently, removing the old flowers before seeds are set, otherwise their flowering period may be shortened considerably. In this respect the well-known variety Maggie Mott is a useful sort to grow, as it rarely sets any quantity of seeds. Jersey Blue Gem has also, within the last two years, become extremely popular, and it is a first-class plant for bedding out or for planting at the front of the mixed border, being particularly free and continuous flowering, yet of neat and compact habit of growth. Old plants wintered in the open are now smothered with bloom and have none of that loose, straggly growth found in many varieties. Other colour forms of this variety have appeared, and it is hoped they will prove as free and useful as the parent plant. After the recent rains herbaceous plants are growing very fast, and close attention should be given to staking and tying, as it is impossible to get the best effect if the growths are once broken down by wind and rain storms.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN,
Brocket Hall, Hertfordshire.

Euphorbia pulcherrima.—Cuttings of this, if inserted some weeks ago, as advised, should now have filled their receptacles with roots and should be repotted into larger pots. The rooting medium may consist chiefly of good fibrous loam, with one part of peat, and a good quantity of sharp sand added. After potting, apply water sparingly until the roots are active again. Frequent sprayings of the foliage will prove beneficial to the young plants, especially during hot weather. The one-year old plants that were rooted late to produce decorative plants in small pots last season will, if potted on, make good specimen plants if the young growths which are produced at the base of these cut backs are reduced to three in number and the old compost is partly removed from the roots before repotting them into pots one size smaller. They should be grown on for a time in a moist atmosphere, in a position near the roof glass, and potted into larger pots when this becomes necessary; at a later date the plants should be grown under cool, airy conditions until about the second week in September. The bracts produced in winter will be greatly improved by this cooler treatment during this stage of growth. Euphorbia fulgens requires much the same treatment as that recommended for the above, although I always pinch this back early and then allow three shoots to develop.

Begonia Gloire de Lorraine.—Early rooted cuttings of this plant will now be ready for transference to the receptacles in which they are to flower; the pots may vary in size from five to seven inches, according to the strength of the plants and also the requirements of the grower, as in many instances the smaller pots are the more suitable for house decoration. The compost for this potting may consist of good turfy loam and leaf-mould, with broken charcoal and sand added. These Begonias resent firm potting and the compost should only be pressed lightly around the roots with the fingers. One other point to remember in the cultivation of Begonias is that they greatly dislike lime. So soon as the pots are well filled with roots give a mild stimulant in the form of soot water, which will tend to give the foliage a dark green colour. A few hanging baskets may also be filled with specimens at the present time, as this Begonia is admirably suited to this purpose. Other winter-flowering Begonias should be kept growing, never allowing them to become starved in their pots before repotting takes place. Fumigate the plants at intervals with nicotine to keep mite in check.

THE KITCHEN GARDEN.

By W. G. STAWARD, Gardener to LADY MARGARET RYDER,
Knowle Gardens, Dunster, Somerset.

Globe Artichokes.—A mulch of half-decayed manure will help to prolong the crop of Globe Artichokes on light, gravelly soils, and applications of liquid manure should be given at frequent intervals.

Salsify and Scorzonera.—These will now be ready for thinning, and as it is difficult to pull the roots out of the ground completely, a sharp pointed stick should be employed to loosen the ground sufficiently, to enable the unwanted plants to be removed intact. Thin the plants to at least ten inches apart, and afterwards apply a dusting of soot between the rows and hoe it in.

Seed-sowing.—Sowings of Endive, Lettuce, Turnips, Radishes, etc., may be made according to requirements. Should the ground be dry, soak it well before sowing the seeds.

Spinach.—Another sowing of the ordinary round-leaved variety may be made in ground that has been cleared of early Potatos or early Cabbages, for as the season advances fresh leaves of this are esteemed and late sown plants do not run to seed so quickly as the early ones.

Brussels Sprouts.—As the early plants of Brussels Sprouts are now of fair size they may have the soil drawn up around their stems to steady them, but if the plants grow very tall and need supports, it is wise to tie them to stakes. If sufficient soil cannot be drawn up about the plants make use of a spade for this purpose, so as to place plenty around the neck of the plants for support afterwards. Dust alum between and soot or slaked lime around the plants to prevent slugs and snails from injuring the "buttons," and keep a sharp look out for caterpillars; the only sure method of dealing satisfactorily with these pests is to pick them off by hand.

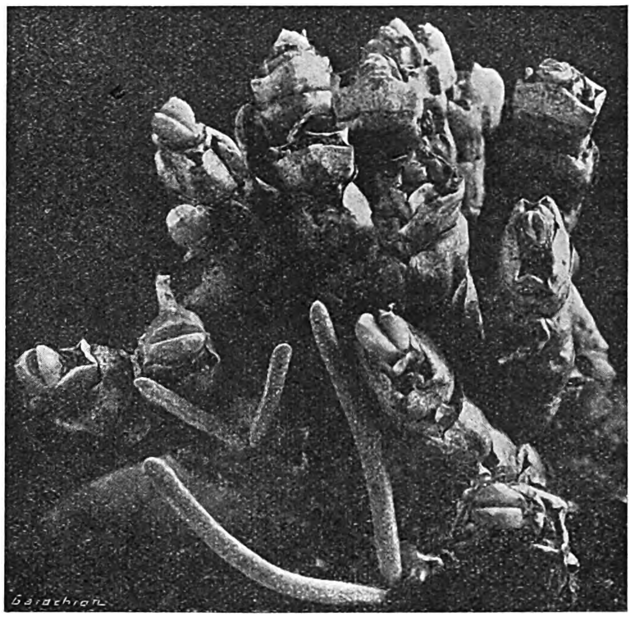

FIG. 12.—MONILARIA CHRYSOLEUCA.

Plant at rest; natural size. (see p. 34.)

Shallots.—So soon as the Shallots have finished growing and the leaves commence to turn yellow, they should be lifted and dried in the sun, after which they may be stored in a dry, airy room.

FOR NORTHERN GARDENERS.

By JOHN HILL, Gardener to ANDREW ARTHUR, Esq.,
Rosemont, Monkton, Ayrshire.

Vegetables.—Vegetable Marrows should be well supplied with water, and have their growths thinned and regulated at intervals to prevent crowding. The leaders should be stopped to encourage the production of side-shoots, on which the female flowers are produced most freely. If sufficient manure was given in preparing the site, no further stimulants will be necessary, but if growth seems poor, liquid manure should be given after watering. All Brassica beds should be well cultivated and before the plants get too tall they should have soil drawn up to them in cases where they are liable to be blown over by the wind, but in many gardens this will not be necessary.

Celery.—Give this crop abundant supplies of water during dry weather and, to prevent quick evaporation, a thin layer of dry soil, scraped from the sides of the trenches, should be spread around the plants. Remove basal side-growths as they appear.

Shallots.—These, having finished their growth, should be lifted carefully and placed under cover, in full sun if possible, to finish the ripening process. The keeping quality of the bulb depends on this being properly done; plenty of air and sun, and a water-proof position, are all that is necessary.

Summer-pruning and Training Wall Trees.—This work should now be carried out, and if stopping of unwanted shoots has been attended to, it is comparatively easy. On fan-trained, stone fruits a supply of young growths should be maintained all over the tree, and laid in temporarily, but care should be taken to straighten the young leaders now, while green, as it is scarcely possible to do this when the growth becomes woody. If the breast wood has been allowed to grow, as is usual, remove all growths not required by cutting them back to four or five leaves, according to the strength of the shoot. The top of the trees should be attended to first, doing the pruning in about three operations, and working from the top to the bottom. Continue to stop lateral growths on cordon Apple and Pear trees, leaving a few leaves each time. Give these plenty of water at the roots, and if they are carrying heavy crops they should be given liquid manure or chemical fertilisers to assist them, or the fruits will be of poor quality. Morello Cherries should have a good supply of young growths laid in all over the tree, all unwanted growths being cut clean away. All growths retained on all wall trees should, if possible, come from the top side of the branches. Extra strong leaders should be stopped, to the benefit of the weaker growths. Where wood-lice are present, steps should be taken to destroy them before Apricots and Peaches begin to ripen. For this purpose I find nothing so good as slices of Potato placed close against the wall at intervals all over the tree, these being examined regularly and the wood-lice destroyed.

ORCHID NOTES AND GLEANINGS.

MAXILLARIAS.

These Orchids are of comparatively easy culture, and thrive well when grown at the warm end of the cool house, in a position where a free circulation of air can be maintained around the plants, and where they may be shaded from bright, direct sunshine. If the atmosphere is allowed to remain close, and constantly charged with moisture, the foliage of the plants will become spotted and unsightly.

As the various Maxillarias pass out of flower, they should receive attention at the roots. The scandent growing sorts, of which M. meleagris and M. tenuifolia are typical examples, are best grown on blocks of wood or small teakwood rafts fixed firmly into pots, as these do not require removing annually unless they become overgrown; some of the old fibre and moss may be removed and fresh compost inserted, fastening this when required with some very thin copper wire. Such compact growing sorts as M. picta, M. arachnites, and others, can be grown in well-drained pots, while the beautiful M. Sanderiana should be planted in a teak-wood basket, and grown suspended from the roof in order that the flowers may be shown to the best advantage, as the flower scapes are often produced in a downward direction; for some of the strong-growing species a little fibrous loam is beneficial in the compost.

Water should be afforded carefully and sparingly after repotting, until the roots are well established in the fresh soil, when ample supplies will be needed each time the compost approaches dryness. A keen search should be made at frequent intervals for thrips, which quickly damage the young growths of Maxillarias. Regular fortnightly sprayings with weak solutions of an approved insecticide will keep these pests in check, but should they gain a hold, dip the foliage in the insecticide, tilting the plants afterwards to allow the moisture to run free from the growths, which may also be cleaned with the aid of a wing feather and a few drops of insecticide. *D. G.*

ANOECTOCHILI.

The genus Anoectochilus is distributed throughout the tropics of the Old World. The species are terrestrial Orchids with small, unattractive flowers which are borne on an erect spike. Their beauty lies in their velvety leaves, and for this reason they should be given a place in every Orchid house. The succulent leaves are ovate to lanceolate in shape and, in some of the species, are beautifully variegated. The following are natives of the Malay, where they are found growing beneath the decayed leaves in dense jungle, from 2,000 feet upwards :—

A. geniculatus is a delicate little plant with fleshy stems two to three inches tall. The leaves are ovate, purplish-brown, velvety and reticulated with gold. The whole plant resembles A. regalis, which is a native of Ceylon, and is probably a form of this species.

A. pectinatus has larger leaves than A. geniculatus. They are green, three inches long and one to two inches wide. The flowers, eight to ten in number, are borne on a spike six inches long.

A. Reinwardtii is, without doubt, the best of the Malayan species. It is a small plant similar to A. geniculatus. The leaves are one to two inches long and one inch wide, deep bronze, with a velvety sheen and reticulated with gold. This is a variable plant and in cultivation the leaves become much lighter. The writer collected a number of plants and endeavoured to grow them in a semi-sheltered position, but not protected from the sun, and it was noticed that the brilliant sheen disappeared and the leaves turned brownish-red.

The members of this genus are considered to be difficult to cultivate and should be grown under bell glasses. They like a warm, humid position, and the compost should consist of one-third fibrous, sandy peat and two-thirds chopped Sphagnum-moss mixed with a liberal sprinkling of broken crocks. Given these conditions, the leaves will remain on the plant for several years. *F. S. Banfield, F.L.S., Malaya.*

INDOOR PLANTS.

LIBONIA FLORIBUNDA.

In this subject we have a small, compact-growing, soft-wooded plant that bears a profusion of tube-shaped flowers which are dull red and orange in colour, while its free-flowering disposition makes it a very useful plant for decorating the conservatory, especially during late winter and early spring.

Cuttings of soft young shoots taken early in the year, inserted in small pots filled with fine sandy soil, placed in a propagating case in an intermediate temperature, and kept close, moist and shaded, will root in about three weeks. When rooted, they should be potted singly into 3-inch pots, using a mixture of two parts fibrous loam, and one part good leaf mould, with enough sharp sand added to keep the compost open, and the plants placed in a house having a temperature similar to that in which the cuttings were rooted. When the young plants are growing freely less fire heat will suffice. Syringe them overhead daily and admit a moderate amount of fresh air; stop the young shoots and support the plants with neat stakes.

In about nine weeks from the first potting enough progress should have been made to admit of the plants being moved into 5½-inch pots which will be found large enough to flower them in, using a compost similar to that advised for the first potting, but with the addition of some dried cow manure passed through a ½-inch sieve. When the plants are again growing freely give more air and gradually accustom them to cool-house treatment; syringe them freely and give frequent applications of liquid manure and soot water.

So soon as the flower buds appear remove the plants to their flowering quarters, in a temperature not lower than 45° by night, where they will continue to flower for many weeks. After flowering, give the plants a slight rest, and prune the growth hard back, and when growth again becomes active pot them on into larger pots and repeat the treatment afforded them as young plants.

Red spider sometimes troubles L. floribunda, but may be kept in check by the free use of the syringe. *J. L. McGoogan, Wisley.*

TREES AND SHRUBS.

CYTISUS SESSILIFOLIUS.

Well-grown plants of this very desirable species are rarely seen in English gardens; but, flowering as it does, in June, when most of the earlier Brooms have ceased, it can be very attractive, as many continental gardeners have proved. C. sessilifolius is a very old introduction, coming to us three centuries ago. Although a native of southern Europe and northern Africa, it is deciduous and perfectly hardy. It makes an elegant, rather twiggy bush of about five feet. The grooved branches are smooth, and the trifoliate leaves so short in the stalk, especially on the younger wood, that they appear to be connate. This foliage is hairless and of a delicate glaucous-green.

The bright yellow flowers, each half-an-inch long, are borne in small racemes at the ends of the current year's shoots, and the flowering period is extended throughout the early summer. Seeds afford the best means of propagation. Like most others of it race, C. sessilifolius is a lover of sun and dry, warm, stony soils. But it does not resent some shade, and can be a charming object in thin woodland.

VINCA DIFFORMIS.

For many years I have grown the winter-flowering Periwinkle as one knows it in southern Europe. That is to say, it is a plant much after the style of V. major, but it is entirely hairless and the smaller flowers, pale lavender or white, have diamond-shaped, or nearly rhomboidal, segments, with the points deflected so that the flower suggests a whirling screw. The blooms, of course, appear from November to spring, but plants much snubbed by frost will postpone affairs until May or even later.

Now there comes from a generous friend a plant labelled V. difformis, which is quite unlike the above, save in manner of growth and flowering season. In this form the leaves are narrower and rather a duller green. The corolla of the flower is a deep violet, and the segments are so narrow that they are little more than thin dagger-shaped rays, straight as wheel-spokes, and sharply-pointed. Is this " the deep purple-blue Italian plant sometimes called acutiflora " (E. A. Bowles: *My Garden in Autumn and Winter*), or is it a western (Spanish) representative of this confusing tribe ? *A. T. J.*

STEWARTIA PSEUDO-CAMELLIA.

There is a fine bush of this tree now in bloom in the grounds of Mr. Wilson, at Cannizarro, Wimbledon. The species is the most recent of the introductions of the genus to this country, and Messrs. J. Veitch and Sons were instrumental in introducing it to the gardens of this country, from Japan in 1879. It has not yet, perhaps, had time to show what it can do in this country, but it seems to thrive better here than the species which have been introduced from America. The flowers are white, made up of five rounded, concave petals that form a cupped bloom. Evidently the specific name alludes to the flowers resembling a single Camellia to which the species is allied, but differs in having deciduous leaves. The orange-yellow, incurving stamens add to the similarity.

It is a beautiful and by no means common shrub in gardens; and in autumn becomes ornamental again when the leaves turn red and bright yellow. The genus is sometimes placed under Malachodendron, and the above name is sometimes spelt Stuartia, in honour of John Stuart, Earl or Bute, but Linnaeus spelt it Stewartia, when describing S. Malachodendron in 1741. *J. F.*

GENISTA CINEREA.

This is one of the most valuable of the tall Brooms, whether as a single specimen or massed in large beds and borders, for which latter purpose it is especially suited.

It averages nine to ten feet in height, and the long, slender branches are very freely furnished with clusters of rich yellow blossoms from about mid-June onwards.

G. cinerea is a native of south-west Europe, and although this is rather a warmer region than the British Isles, this shrub is perfectly hardy at Kew, where it thrives and flowers freely in beds and borders, and semi-wild in the grass of the open woodland. One peculiarity is that the plants at Kew do not produce good seeds, but cuttings root readily if inserted during August in a bed of sand or sandy soil in a cold frame.

Its nearest ally in point of height and season of flowering is the Madeira Broom, Genista virgata, which produces seeds freely, self-sown seedlings being common in the shrubbery borders and the woodland. In flower, however, it does not produce the gorgeous mass of rich yellow colour which is the outstanding feature of G. cinerea. *D.*

NOTES ON SPECIES OF RHUS.

The genus Rhus embraces some of the most beautiful of plants for autumnal colour effect that it is possible to cultivate in our gardens. Many of the species are notorious for the poisonous effect which they have on the skin, but, if this is realised at the beginning, and reasonable care taken when any necessary pruning or propagation is being done, the advantages gained by having a wonderful display of multi-coloured foliage will outweigh the disadvantages. Generally, it may be taken that the pinnate-leaved kinds, such as R. Vernix, R. succedanea, R. vernicifera and R. trichocarpa while, perhaps, not being quite so virulent in their effect as the real Poison Ivy (R. Toxicodendron and its var.

Rydbergii), nevertheless do set up in some people a violent irritation on the arms and hands, which will prove very difficult to get rid of.

Of the many species and varieties in cultivation, the following are particularly worthy of notice :—

Rhus cotinoides (Chittam Wood), a small, deciduous tree or large shrub, which has a localised distribution in the south-eastern United States of America, and would appear to be somewhat scarce in cultivation, although it was sent to England over forty years ago by the late Professor Sargent. The decorative value of its flowers is negligible compared with the wonderful glory of its autumn foliage, which displays all shades of scarlet, claret and orange, especially if the plants are growing in rather hungry, dry soil. Rich conditions at the roots tend to keep the leaves green until they fall.

Propagation may be effected by cuttings of the current year's wood, made in July and August, about four inches long, with a slight heel of older wood attached or severed at the junction of the current year's wood and that of the previous season. The cuttings should be inserted in pure sand in a frame having sufficient bottom heat to maintain a temperature of 65° to 70°. Layering suitable branches provides another method of increase.

R. Cotinus var. atropurpurea differs from the type in having all the young leaves and wood a good purple colour ; care should be taken when propagating to select the best-coloured form. The remarks on the propagation of R. cotinoides are equally applicable to this variety, except that R. Cotinus var. atropurpurea will be found easier to propagate. The type is particularly decorative in late summer on account of its flowers, while the foliage assumes a rich yellow colour before it falls.

R. trichocarpa is a native of Japan, and deserves to be much more widely grown, as it stands in the front rank among plants that give fine foliage effects in autumn. Unlike the two mentioned previously, R. trichocarpa belongs to the pinnate-leaved section, and while in its native state it grows into a small tree, in cultivation it forms a bush from four to six feet high. Contrary to the general belief that all pinnate-leaved Rhus must be propagated by root-cuttings this species may be readily propagated by cuttings made of the current year's wood with a slight heel of older wood attached, and inserted in the same way and at the same time as recommended for R. cotinoides. The cuttings will root in about a month, and therefore may be established in pots before the winter sets in ; they should be kept rather dry during the winter and planted out the following spring. It is advisable to have the hands and arms protected from the sap when making cuttings of this species.

Rhus typhina is more generally seen in cultivation than the other kinds, as it will grow under the adverse conditions which prevail in and around large towns. The flowers and fruits of the female plant are quite decorative, but its chief value is derived from the foliage in autumn which takes on various shades of orange, red and purple.

Along with such subjects as Ailanthus glandulosa and Paulownia imperialis, it may be used as a foliage plant in summer, and for this purpose it is best planted in groups or in a bed, where it must be pruned hard back every spring just before growth commences. Only one or two shoots should be allowed to each plant, and the soil will need to be heavily manured. This treatment will result in an annual growth of five to six feet, with leaves from two to three feet long.

The variety laciniata is worth growing on account of its finely-cut foliage.

The best way to propagate this species would appear to be by using root cuttings, which may be inserted in very sandy soil in early spring.

Seeds of several species of Rhus are regularly offered by American and Japanese seedsmen and form a ready means of increase, but many of the kinds so offered are on the border line of hardiness, although R. glabra and var. laciniata and R. Osbeckii are well worth cultivating and will prove quite hardy in most places. *F. P. Knight, Codsall.*

FIG. 13.—MONILARIA CHRYSOLEUCA.

In flower; petals white stamens rich yellow (see p. 34).

ROSE GARDEN.

ROSA RUGOSA VAR. REPENS.

A good many years ago, when visiting a beautiful garden formed by two keen lovers of flowers at Birkshaw, in Dumfriesshire, I was struck with the beauty of a prostrate form of the white form of Rosa rugosa hanging over a bank of what had been a gravel pit.

By the way, I revisited this garden some years afterwards. One of the garden-lovers, alas! has gone over to the majority, and the other had removed to another home. There was on my second visit to what had become a wilderness no sign of this white trailing Rose.

I have had similar plants in my garden and have given two plants of the white-flowered one a companion in the form of R. rugosa var. repens rosea, a still more charming plant with flowers of a pleasing rose. These plants are high up on a steep rock bank in front of my house, where they were planted in the autumn of 1927. They flowered last year but not profusely, and this summer have begun to bloom well and give evidence of a wealth of flower as the season advances. I believe these varieties originated in the nursery of Mr. T. Smith, at Newry. They do not appear to be well known even to the nursery trade, but are worth noting for planting in autumn. R. rugosa var. repens alba is very charming with its maltese-cross-like blooms, but R. r. var. rosea is even more attractive. *S. Arnott.*

ROSA MIRIFICA.

Those who take a delight in wild Roses and single Roses generally would be pleased with this wonderful wild Rose from the Western United States, and now flowering in Kew Gardens. The blooms are two inches across or more, and to all appearances are borne singly at the ends of the branches, produced during the second year. The leaves are light green, and made up of three to five leaflets, mostly three, the terminal one being obovate-cuneate, and simply toothed around the outer end ; the lateral ones are slightly asymmetrical, as if they intended to be lobed or divided into two, otherwise they are like the terminal one. All are so closely contiguous that they make the shortest Rose-leaf I have seen. The stems are hispid, with glands, while the flower stalk, calyx and fruit are thickly clothed with similarly stalked glands, mixed with aciculi or slender, needle-shaped prickles. The flowers at first are deep rose, fading to light rose and then pink, with a purple base to the petals. Altogether the make up of this Rose is quite distinct from any species I have seen in cultivation. *J. F.*

PLANTS NEW OR NOTEWORTHY.

CALCEOLARIA BENTHAMI.

THIS alpine, perennial species will probably prove one of the most useful of recent additions to the genus. During the Andean Expedition 1925-6 and 1926-7 seeds were collected from two localities; first, in the Valle Escondido, Palan Mahuida, where the plant was growing in sand, among rocks, exposed to full sun, at an elevation of 6,000 to 7,000 feet, and later, at Vega Lolog, Collunco, on grassy banks, and in shady copse in soil of a sandy nature. Although the conditions were different, the height of the stems was practically the same—a maximum of twelve inches.

Seeds were sent home, sown, and in due course flowered in small pots. But the value of C. Benthami was not discovered until it was planted out permanently in the open ground. A large number of plants was left out during the winter, both in the open field and on the rockery. In both cases no losses occurred, and the plants have increased considerably in size. As a matter of fact, the plant exhibited at a recent meeting of the R.H.S. (see p. 452, Vol. LXXXV), had spent fifteen months unprotected in the open field, and was only dug up a few days previous to being exhibited.

Under cultivation this Calceolaria forms neat clumps, and flowers profusely. A specimen I have just examined has forty-three stems and each stem carried on an average twenty flowers, making a good display which lasts for several weeks. In a moister situation, secondary growths might prolong the season. Propagation is easily effected by division or seeds. *J. Comber, Nymans Gardens.*

CIRCIUM OCCIDENTALE (NUTT.) VAR. COULTERI (JEPSON).

THE Thistle family—as grouped by the botanist—embraces a bewildering number of genera many of which have little resemblance to what ordinary mortals recognise as a Thistle. There are probably few races of mankind who are not acquainted with them in some form or other so that their very universality may well be accepted as an aid to faith in the Edenic story as to their being part of the punishment for our sins of disobedience.

There are species that are a plague to the farmer and a pest to the stock-breeder, but the gardener looks upon them from another point of view, and knows that among them are plants of good decorative value and well worthy of a place in the garden.

Our European types vary from dwarf alpines to stately and finely-proportioned plants of six feet in height, with a great diversity of foliage, and flowers ranging from pure white and yellow to all shades of pink, lilac and purple.

In California and the neighbouring states are several species of the genus Circium, which have rich scarlet flowers, and the introduction of these is much to be desired. From the description of those to be found in the various "Floras," C. arizonicus is, perhaps, the most brilliant, but until that species is introduced, we must be content with the plant under notice, C. occidentale var. Coulteri (see Fig. 11, p. 23), a most striking and decorative subject, growing five feet high, stout and straight, clothed throughout—leaves, stems and flower-heads—in soft, white, cottony wool, and producing its soft scarlet flowers from the axils of every leaf.

In its early stages the large, finely-cut, basal leaves are like silver, and the whole plant becomes only slightly less white when nearing its full height. No opportunity has yet occurred of using this species in the mass, and our first efforts ended in disaster. The seeds germinated very freely but the young seedlings all perished when transplanted. The difficulty in saving plants was overcome by sowing the comparatively large seeds singly in small pots. The best time to sow is in June or July, wintering the plants in a cold frame, as they resent heat and greenhouse treatment. When large enough they should be moved into five-inch pots and planted out in the early spring in their flowering quarters.

Much has been written in the more popular books on the American wild flowers about these scarlet Thistles, but from none can it be learned whether this plant is perennial or not. It has all the appearance of being only of biennial duration. A friend who recently returned from a visit to America, and whose opinion I value, told me he considers this the most desirable novelty seen in the United States, and it may easily be imagined that a large group would be very telling.

Circium occidentale var. Coulteri is found near Los Angeles and on all the coastal mountain ranges at from 2,000 to 8,000 elevation. It has been introduced into American gardens and seeds are obtainable from Mr. Theodore Payne, the well-known seedsman and nurseryman of Los Angeles city.

ALPINE GARDEN.

DIANTHUS SYLVESTRIS.

AMONG the many beautiful, dwarf alpine Pinks which brighten our rock gardens during the month of June, few are more beautiful than Dianthus sylvestris, which, according to the late Reginald Farrer (*The English Rock Garden*) should be D. inodorus—apparently a name given by Linnaeus prior to that of D. sylvestris, although the latter is retained in the Kew *Hand List of Rock Garden Plants*.

However, I have no desire to enter into a discussion on nomenclature, but wish merely to extol the beauty of this lovely denizen of the Alps, which is quite easy to cultivate, and will flourish in the humblest rock garden if planted in a warm, sunny and well-drained position, in light soil containing plenty of chips and small stones, and will there form a dense cushion of slender, bright green, not glaucous, leaves. If the plants are raised from seeds the flowers will vary somewhat, therefore care should be taken to secure a good form, with vivid, rich rose-pink blooms, slightly paler at the centre, one or two flowers usually being borne at the ends of wiry, spreading stems four or five inches in length; these flowers are usually produced quite freely, so that a patch of two or six good plants of this Dianthus will form a landmark in the rock garden at the present season.

There is a pure white form of D. sylvestris, although I do not know whether it is at present in cultivation, but variety frigidus is the best form in cultivation, being of even denser and more compact habit than the type, and more ample in its blossom—a real gem, deserving of a very choice position.—*Kent.*

MECONOPSIS BETONICIFOLIA VAR. BAILEYI.

MR. EDWARDS, in his notes (*Gard. Chron.*, June 22, 1929, p. 473), mentions Meconopsis betonicifolia var. Baileyi as having been a great source of attraction at Kew. This will, I suppose, be the Blue Poppy known to most gardeners and listed in seed catalogues as M. Baileyi. It is not included in the masterly summary of the genus (thirty-three species or thereabouts) in *The English Rock Garden*, it is, however, generally supposed to have been discovered some few miles from Gangtok in the Tibetan Alps, by Major Bailey, about sixteen years ago. Little more was heard of it until Mr. F. Kingdon Ward sent home seeds of it in 1924.

Many may remember it as first exhibited at one of the R.H.S. meetings in April, 1926. Now it is fairly common, and a few weeks ago an extensive colony in full bloom attracted considerable attention, flowering in the mass, in the rock garden on the site of the old mansion-house of Ibroxhill, now one of Glasgow's public parks.

This Asiatic Poppy is, perhaps, the most accommodating member of a genus which has the reputation of being somewhat impatient of the cultural methods practised in the majority of British gardens. Climatic conditions here, scarcely approximate to those which obtain in the native home of the genus, and have probably more to do with success or failure than many cultivators would admit. Although usually classed as perennials, Meconopsis are best treated as biennials, and a stock of plants should be raised from seeds each season. They require considerable root room, and for their maximum development require a well-worked, gritty soil, with a minimum depth of from two feet to a yard, to supply nourishment and give anchorage to the long, thong-like, fleshy roots. *Jonathan Fiona.*

HARDY FLOWER BORDER.

PULMONARIA AFFINIS.

FOR many years I have been puzzled with a Pulmonaria grown in gardens and appearing under such names as P. sibirica, and P. saccharata, although the plants appearing under them were very dissimilar. The correct name is that forming the heading of this note. The plant is a strong grower, flowering in April and May on stems eight to twenty inches high. The flowers are large for the genus, red at first and then bluish violet. After flowering, the radical leaves grow to great size and beauty. They are oval, narrowed to a long point, suddenly contracted into the petiole, twice as long as broad, and dark green above, marbled with large white blotches.

The species is widely distributed in the centre, east, west and south of France, in woods, meadows, and humid bushy places. It also occurs in Spain and Italy, as well as sub-spontaneous in other countries. *J. F.*

PERENNIAL SPECIES OF LATHYRUS.

To the species mentioned by J. Comber, on p. 366, Vol. LXXXV, I would add Lathyrus tuberosus, the Tuberous or Fyfield Pea. This plant appears to have been introduced into Britain by the Dutch in the sixteenth century, possibly because its tubers are edible. It is found growing commonly about Fyfield, in Essex, and also in Canvey Island, and some half-a-dozen other localities in different counties. Its flowers are very similar to those of L. sylvestris, but smaller and fragrant. Like that species, it is a climber and will reach a height of six feet. In my garden at Hale End it grew well on a chalky bank and also on the rockery, trained up supports of cane and wire, but it is not to be recommended for rockeries on account of its running underground stolons, which, although not aggressive, form tubers at distances of a foot or more from the parent and so are liable to overrun a good area in ten years or so. It is, however, so dainty and attractive a plant when well-grown and flowering freely from June to August, that it is worth trying from seeds.

Another wild species is L. niger (Orobus niger), the Black Bitter Vetch, found occasionally in rocky woods in Scotland. This is not so striking a plant as most of the others, but it is of interest for its purple flowers which turn blue as they fade, and the long black pods, and also because it will be quite happy and flower well in shady places and under trees. It grows to a height of two feet and, although not a climber, it needs a little support. *C. Nicholson, Nansgwithick, Tresillian, Cornwall.*

BULB GARDEN.

ALLIUM SCHUBERTI.

LAST winter I had a sheet of a dried specimen of Allium that had been lying about waiting for a name for twenty years or more. One referee had determined it to be A. Porrum, but I soon referred it to A. Schuberti, which is a native of Syria, including Palestine, for the specimen had been gathered at the Waters of Merom. A specimen in the Kew Herbarium had come from the same place.

The flowers are of a dull purple in colour, and not particularly showy. The plant is remarkable for flowering first on short stalks, and when these are in the fruiting stage, others are in full bloom on peduncles six to eight inches in length, giving the umbel some semblance to a porcupine. Many of the flowers have to be cut away to enable the head to be placed on a herbarium sheet. It was in cultivation at Kew prior to 1902 and was figured in the *Botanical Magazine*, tt. 7,587–8. Live specimens were recently shown by Mr. Amos Perry. *J. F.*

ALLIUM TRIQUETRUM.

To most of us, I think, the odour of the majority of the Allium species is so objectionable that they require to possess a considerable degree of floral charm to ensure their cultivation. This a considerable number of the species do possess and, if proof were needed for those who do not know the genus well, the authority of the late Reginald Farrer may be cited, as he devotes rather more than three pages of his *English Rock Garden*, to a consideration and running commentary upon the Alliums. I am glad to observe that he wrote very favourably of one which has been grown by me for many years, but which does not as yet appear to be represented in many gardens, and that is, A. triquetrum.

It is a capital subject for shrubberies and for naturalising in grass, and may even be utilised in corners of the rock garden, where its seedlings cannot harm choice subjects. Farrer stated that it is "a plant of great attraction," with its triangular stalks and heads of clear white flowers which droop gracefully from these stems. Incidentally, it may be mentioned that these triangular stems, which attain a foot in height, serve the purpose of depositing the seeds away from the parent, as they fall over and the heads, with the precious seeds, lie about a foot or so from the parent.

This species comes from Spain, where it inhabits shady banks and moist places, but it will grow almost anywhere. Its odour is only apparent when the plant is touched or bruised. It flowers in June, and should be planted two inches deep in good loam. *S. Arnott.*

NOTICES OF BOOKS.

American Rock Gardens.

THIS little book* is intended to give the novice who knows nothing of the subject a first lesson in the making of a rock garden and the growing of rock plants. That the author, who holds important horticultural positions at Harvard University, has achieved his object, will be conceded by those who realise that the public he is addressing is American, a country in which the rock garden is still in the germinating stage. To English readers the book offers little that is new or helpful. At the same time, the general principles of rock garden construction (these being adapted from the works of M. Correvon and Mr. William Robinson) are still so little comprehended by many of our amateurs that Mr. Hamblin's pages might be read by some of them with profit.

A rock garden in New England does not seem to be a very happy possession if one can judge by this author's personal worries. He tells us it demands more upkeep "than any other kind of ornamental garden." To him a rock plant is, until well established, "a sick child, and a rock garden an orphanage with all the children ill." He admits having had more failures than successes in his own garden, and in words that would adorn an epitaph, he mourns in "sadness of heart . . . the long list of plants gone back to their native happy country." If all this, and there is a deal more, were a general experience, it might help to explain why Americans have avoided such gloomy companionship as a rock garden offers. But we know that it is just the contrary, that even in New England this branch of gardening offers amenities comparable with any other.

Much of Mr. Hamblin's advice on the care of alpines is sound and practical, but like most American gardeners, he manages to put in more fussing over the question of lime versus acidity than we consider essential. He very rightly advocates a wider use of native American plants, but his lists of these, admittedly incomplete, suggest that the alpine flora of the New World is, even with him, still a long way off its due recognition. He regrets that "there are far too few small shrubs in nature, and most of these have little value as rock shrubs." Most of us have found the boot on the other foot, the difficulty being not the shortage of material, but to provide accommodation for the multitude of claimants, and one wonders what Professor Sargent and Mr. E. H. Wilson, both associated with Harvard, would say of such an amazing statement! It is obvious that this author and, one may presume, the general run of New England rock gardeners, have yet to realise the existence of the dwarf Rhododendrons, to mention but one genera rich in rock shrubs. But while America's own dwarf Rhododendrons, Kalmias and several other important groups are not even mentioned in these pages, it is, perhaps, too much to expect this author to allude to plants of more recent discovery.

One notes, however, the saving grace of modesty and sincerity in Mr. Hamblin's pages. Even if the prospects he offers those who attempt alpines are anything but cheerful, most of his readers who do not aspire to "operate" a "high-power rock garden" will gather some useful hints from his chapters. The reproductions are deplorable, and a poor compliment to Mr. Washington, who provided most of the subjects. *J.*

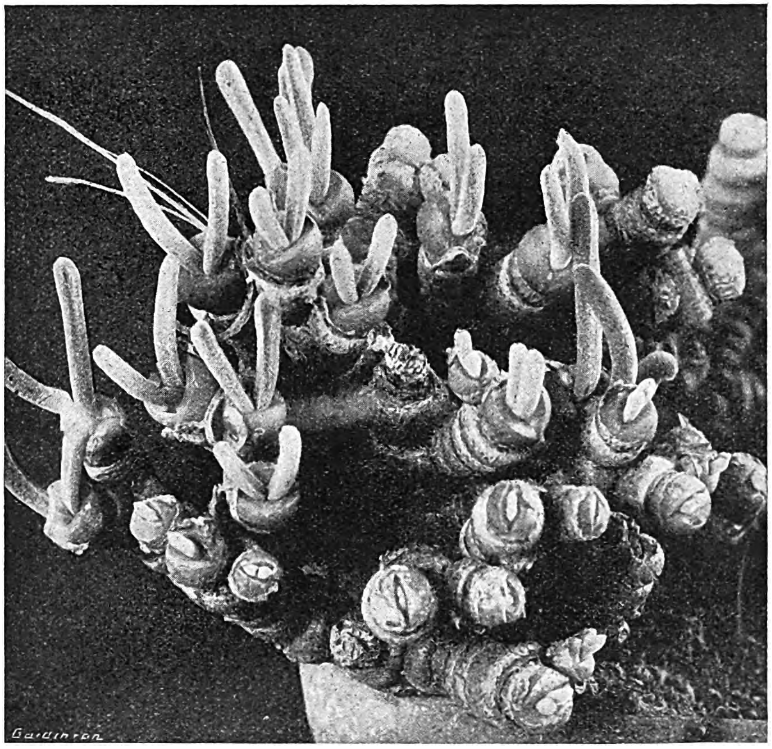

FIG. 14.—MONILARIA MONILIFORMIS.
A plant just commencing to grow natural size. (see p. 33).

Garden Lilies.

DURING the past ten years more books on Lilies have been published in North America than have appeared in Britain during the present century, and if none of them adds anything to our knowledge of the genus, they show that, although gardeners in the United States and Canada have been a little slow to appreciate the interest and pleasure inseparable from the cultivation of Lilies, they are rapidly making up for lost time.

Miss Isabella Preston has written a readable little book on Lilies*, and in its compilation has drawn on her experience of them as a member of the horticultural staff of the Government Central Experimental Farm at Ottawa. Where her brief experience and the limitations imposed on Lily growers by the natural conditions prevailing at Ottawa do not permit her to write from first-hand knowledge on any particular point, the authoress wisely draws on recognised sources which will be familiar to those of our readers who are interested in Lilies.

In common with most works of the kind, which have been published in North America, Miss Preston's book is intended for Canadian and American readers, for the climate and general conditions prevailing in Canada are as unlike those of Britain as is possible. For that reason, English readers will not turn to the book for help in the management of Lilies, but, none the less, they will be interested in the behaviour of familiar species in Canada. Our native L. Martagon, for instance, although of strong constitution, has proved difficult to establish in Ottawa, yet L. monadelphum, another European species, has shown itself complaisant there. On the other hand, L. regale and L. speciosum flourish, although, as is the case here, the flowers of the latter are liable to be spoiled by autumn frosts. L. auratum does not appear to grow readily at Ottawa.

Miss Preston has had some experience in the raising of hybrid Lilies, but a perusal of her book does little to remove the impression that neither the genus itself, nor gardeners in general, have benefited by the efforts of hybridisers. It may still be stated with truth, as was written twenty years ago, that of all the hybrid Lilies which have been produced by human aid, only one—L. Parkmanni—is an improvement on either of its parents, and like most hybrid Lilies, that has a poor constitution.

In one or two technical points there is room for expansion in a future edition of Miss Preston's useful book. For example, the object of potting up imported Lily bulbs on their arrival is not solely so that any which develop disease may be destroyed, but because potting usually induces a quick and satisfactory root-action. Again, L. monadelphum should be added to the list of the species which should be planted in early autumn.

The book is well illustrated with photographs of species and hybrids, is well printed, and slips conveniently into the jacket pocket

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* Publisher; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* Editors. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar, 7818.*

PROBLEMS OF PLANT LIFE[*]

III.—Studies in Fertilisation.

ALTHOUGH vague ideas respecting the fertilisation of plants have existed for ages it is easy to see that until the discovery of the cell such a subject must have been extremely problematical. Much misunderstanding arose respecting the function of pollen, but when the microscope came into use, and thin sections of stigmas and ovaries could be made with the microtome, it was possible to trace the whole process in detail. A pollen grain reached the viscid stigma, threw out a tube which penetrated the cells and reached the ovule, and so secured to the female element the essential for reproduction.

Perhaps the earliest observations on the subject of fertilisation were those which the Arabs and neighbouring races made on the Date Palm. So long ago as 1694, Dr. Cammerer or Camerarius, following a custom which was then in vogue, published an essay bearing the title *A Letter on the Sex of Plants*, in which he recapitulated what the ancient authorities had stated respecting the parts of flowers, and the reproduction of plants. He arrived at the conclusion that the pollen represented the male element, and the ovary the female, proving his contention by cultivating both monoecious and dioecious plants, and showing that if the pollen-bearing flowers are picked off in time to prevent fertilisation no fruit will be formed, while, conversely, if the part bearing the ovary is allowed to have pollen it becomes fertile. This practical result was accompanied by a discussion of a number of theories on the sexes of plants and fertilisation in general, and Linnaeus was not slow to acknowledge that he had rendered a useful service to the study of plant problems.

From the time of Camerarius things began to assume a more strictly scientific aspect, so that we may regard the opening years of the 18th century as the period in which true ideas of plant-fertilisation began to take shape. It was not, however, until the middle of the century that an experimenter arose who gave himself up to the cultivation of plants in order to demonstrate the methods of fertilisation. And even Kölreuter (1733–1806) adopted certain views which now appear fantastic. Using the microscope for the examination of pollen grains he came to the conclusion that the fertilising property is due to an oily fluid which the pollen secretes. On the stigma of the pistil he found a similar fluid, and concluded therefrom that fertilisation consisted in a union of these fluids, just as an acid and a base form a salt."

Although he showed by these suggestions that he had not solved the mystery, Kölreuter nevertheless rendered good service by investigating the means by which pollen is transmitted. He knew that while the wind acted as the carrying agent in the case of those plants which are provided with catkins certain other flowers are invariably fertilised by insects. In particular he experimented on hybridisation, a problem which eventually claimed the whole of his attention. Among the plants which he used in these researches were various forms of Tobacco; Columbines, Mulleins, Pinks and other plants were also used, and although his observations were not always correctly interpreted, and his methods were not invariably such as would be employed to-day, by crossing the hybrids which he had produced he arrived at results which were a kind of foreshadowing of those which rendered the name of Mendel so noteworthy a century later. In one respect both these distinguished men shared a like fate. Their work was overlooked and neglected, and not until long after their death were their names rescued from oblivion.

Meanwhile, another botanist who was destined to win fame in connection with fertilisation problems was coming to the fore. This was Conrad Sprengel. He was born in 1750, and at the age of forty-three brought out (in the year 1793) a work which embodied a large series of observations on flowers. On these observations he based a general theory of fertilisation which largely holds good to-day. He noted the fact that the nectaries of flowers are usually carefully guarded against injury from rain. Observing that, while wind-fertilised flowers were usually inconspicuous, others had a variety of colours, he concluded that brilliancy was intended to attract insects. But this carried with it the further argument that insects must have some purpose in view. They were found to be pollen carriers, and it was clear either that the pollen served some useful end either to themselves or the flowers, or else that they accidentally carried the pollen while in search of nectar. Thus he was led to study in detail the mutual relations between insects and flowers. He found that certain blossoms were capable of being visited only by special forms of insect life, and discovered that in some plants the pistil and the stamens fail to ripen at the same time, thus rendering it impossible for them to be self-fertilised. This led him to the conclusion which he expressed in the formula—Nature does not appear to desire that a flower be fertilised by its own pollen.

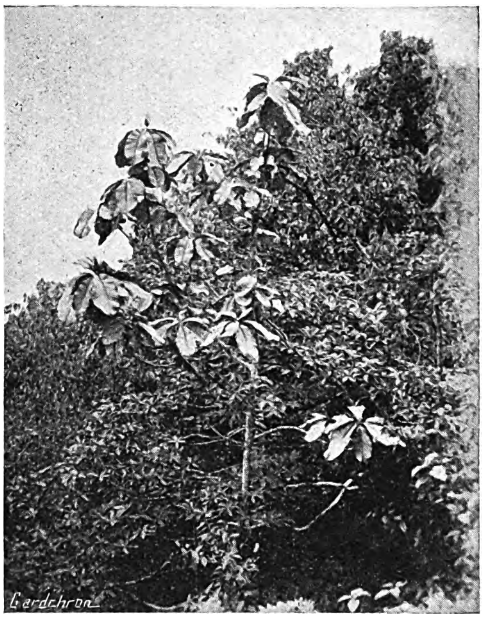

FIG. 15.—MAGNOLIA ROSTRATA IN BUD.

It is easy to see from the foregoing how the way was gradually being prepared for the advent of Darwin, who succeeded in rescuing Sprengel from the oblivion which at one time seemed to threaten him. And here we revert to our last paper dealing with the mystery of the cell. A striking phrase occurs in a recent work on biology[*] which deserves to be quoted in this connection. "Undoubtedly", states the author, "the greatest service to biology that has been performed by modern cell-research is its having given us our present knowledge of the course and significance of fertilisation." By the discovery of the cell the way was made clear for the study of the ovule, and when this important part of the plant had been laid bare it was possible to show the direct relationship which existed between it and the pollen grain. It is interesting to note, however, that the study of animal fertilisation went hand in hand with that of plants, each throwing light upon the other. Just as the botanist saw the pollen tube penetrating the style and working its way to the ovule, so the zoologist saw the spermatozoon penetrating the egg. The first to actually see this, so far as authentic records go, was Hermann Fol, of Geneva, so recently as 1879. When we consider what rapid strides have been made during recent years in biological research it seems almost incredible that during the life-time of many of our readers these startling facts should have been unknown. What, to-day, is a common-place, was still a mystery or something to be accepted with caution and suspicion half-a-century ago.

Into the later history of this branch of research into the problems of plant fertilisation it is not necessary to enter, since it is known to every student of botany. It is interesting, however, to learn something of the weary processes, the patient toil, the speculations, theories and hypotheses by which the way has been opened for a Darwin, a Lubbock and others to tell us the wonderful story of the fertilisation of plants. *Hilderic Friend.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.[†]

XXV.—Three Epiphytic Rhododendrons.

That some species of Rhododendron are habitually epiphytic has long been known. Sir Joseph Hooker, more than seventy-five years ago, wrote that "much undue importance has been given to the fact of some kinds growing habitually epiphytically (R. Dalhousiae, R. camelliaeflorum, R. pendulum), and it has been supposed that much difficulty must attend their cultivation."[‡] And he goes on to mention that he had seen all these species growing on rocks, and that wherever paths are cut through the forest, seedling Rhododendrons, epiphytic and not, may be found in hundreds springing up on the banks—a fact to which every botanist who has travelled on the Burma or Assam frontiers can testify. Hooker pointed out that the reason why these species have taken to the tree-tops is doubtless owing to the lack of light below; the more vigorous undergrowth gives them no chance. Given favourable conditions and a fair field, they will grow on the ground, and such species as R. pendulum even, whose very name suggests "epiphytism de luxe," may then grow erect.

All this may be true, but it is by this very means, so we have always been taught, that *all* epiphytism has been brought about, including that of the Orchid family. Any number of epiphytic Orchids may, under certain conditions, be found growing on rocks. No doubt epiphytism has been carried to greater lengths in the Orchid family than in the Ericaceae, and there may be lots of Orchids which grow only as epiphytes—if only because in the low, damp, swampy forests where they are found, there are no rocks for them to grow on. Species of Aeschynanthus, too, which are ordinarily epiphytic, are just as happy on rocks. Even in England one may see the same process at work; in a damp, dark Devon glen, the Hart's-tongue Fern, which here normally grows on the ground, or on rocks, may be found growing on trees. In short, epiphytism has no creed of its own; it is simply a means to an end.

---

[*] Previous studies appeared in our issues of April 13 (p. 279–80) and June 15 (p. 440–7), Vol. LXXXV.

[*] *The History of Biology*, by Erik Nordenskiöld.

[†] Previous articles on Mr. F. Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; March 2, 16, 30; April 13, 27; May 18, 25; and June 1, 15 and 29, 1929.

[‡] *Journal* of the Royal Horticultural Society of London, 1852.

Epiphytic Orchids, as usually grown at home, are not grown on trees; but they *are* grown under glass. Whether growers find more or less difficulty with the epiphytic species, as compared with ground Orchids, is beside the point; and, of course, with cultivated Orchids it is the epiphytic habit which is normal, whereas with Rhododendrons it is the terrestrial habit which is normal. But it makes no difference, the principle is the same. And the point is this. The difficulty to be faced in the cultivation of epiphytic Rhododendrons is not that they *do* normally grow as epiphytes, but that they *can* do so. In other words, the difficulty is not to reproduce suitable soil conditions, but to reproduce a suitable atmosphere. One has merely to glance at the region in which epiphytic Rhododendrons are most commonly met with—the temperate rain forest of the monsoon countries, between 6,000 and 10,000 feet altitude—to realise the truth of this. Such atmospheric conditions—perpetual saturation during the summer is one of them—can rarely be even approximately met at home.

If, then, Hooker intended to convey the impression that his epiphytic species R. Dalhousiae and the others, could be cultivated in the open as easily as R. arboreum, R. Falconeri, and the rest, he was clearly wrong. So far as I know, there is not a garden in Britain where R. Dalhousiae or R. camelliaeflorum grows in the open; but if there is such a favoured spot in Cornwall, or in Ireland, or on the west coast of Scotland, there are, at any rate, far more gardens where Rhododendrons are well grown, but, which are out of the running so far as most of the epiphytic species are concerned. But if Hooker simply meant that, given adequate protection, the epiphytic species could be grown just like any other species, of course, he was right.

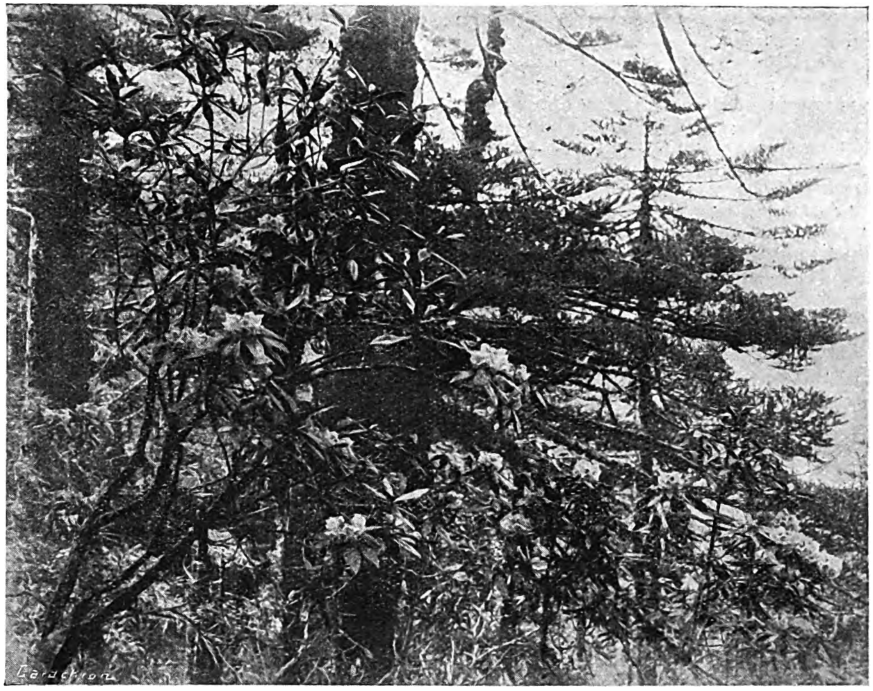

FIG. 17.—RHODODENDRON-CONIFER FOREST.
A 'barbatum' Rhododendron in bloom; alt. 10,000 feet.

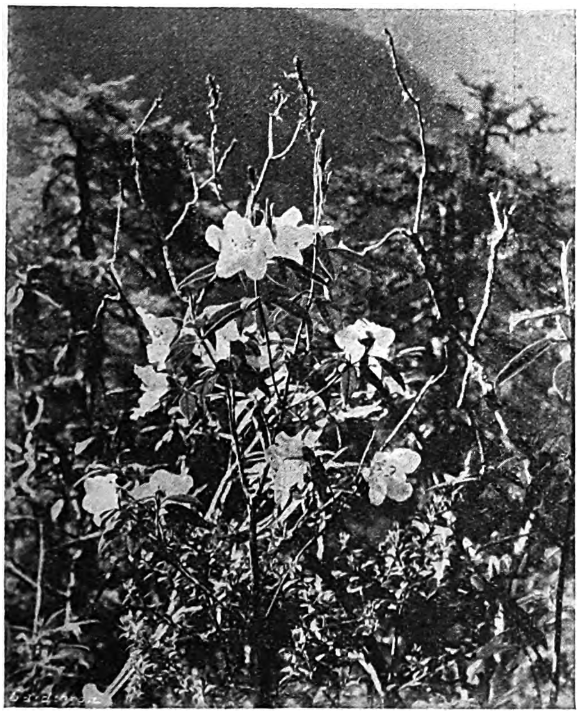

FIG. 16.—A FRAGRANT EPIPHYTIC RHODODENDRON.

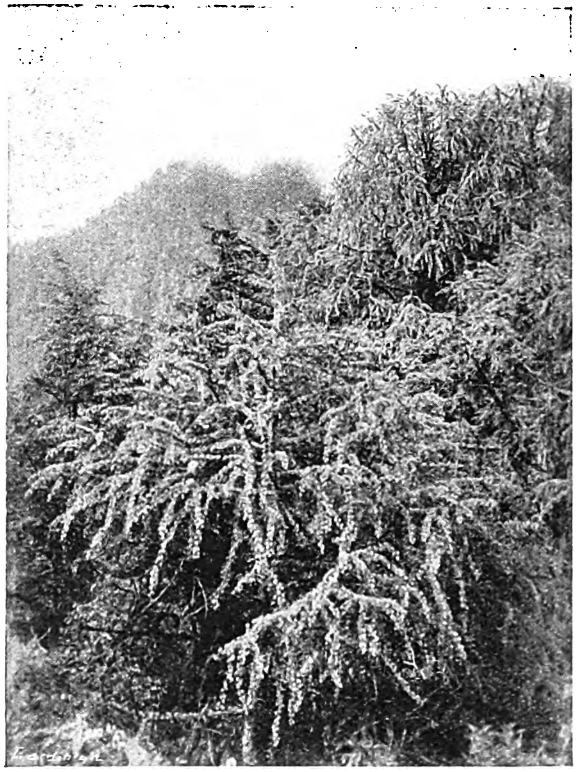

FIG. 18.—LARIX GRIFFITHII.

However, there are certain species which have become much more closely adapted to an epiphytic existence than those mentioned above. Rhododendron vaccinioides and its allies, for example, are epiphytes first and last. The tiny, Box-like leaves, recalling those of certain Gaultherias, and the extraordinary, tailed seeds, seem to be especially designed for an epiphytic existence. True, I have once found R. vaccinioides growing on a rock, and it is not uncommonly met with on fallen logs; but that does not vitiate the inference that it is a true epiphyte. Most of the epiphytic Rhododendrons, however, are almost equally at home on cliffs; and in the forests where they grow, suitable cliffs are common enough.

In the Delei valley I found seven species which grew either habitually or alternatively as epiphytes. One of the best was R. dendricola, which has been referred to in a previous article. When first discovered on the Burma frontier in 1914, it was described as growing on the tops of lofty trees, but since then I have repeatedly met with it growing on rocks, or on an open ridge. Nevertheless, its proper place is undoubtedly up in the tree-tops, where alone it does itself full justice. R. dendricola may be found so low down as 4,000 feet, and so high as 7,000 feet. The flowers are snow-white, with or without a yellow streak on the upper lobe, or occasionally flushed rose, very constantly in trusses of four (never more) and fragrant. In the Delei valley, R. dendricola flowered as early as the first week in April, but in the Seinghku valley it was in flower so late as the middle of May. It is a gracious plant, and the only difficulty likely to attend its cultivation is the fact that it will have to be grown under glass.

Rhododendron vaccinioides was not rare in the Delei valley, although I did not see it in flower. Nor is it worth growing. In the Seinghku valley grew not only R. vaccinioides, but two other species of the same series, one of which, with bright orange flowers, was quite attractive.

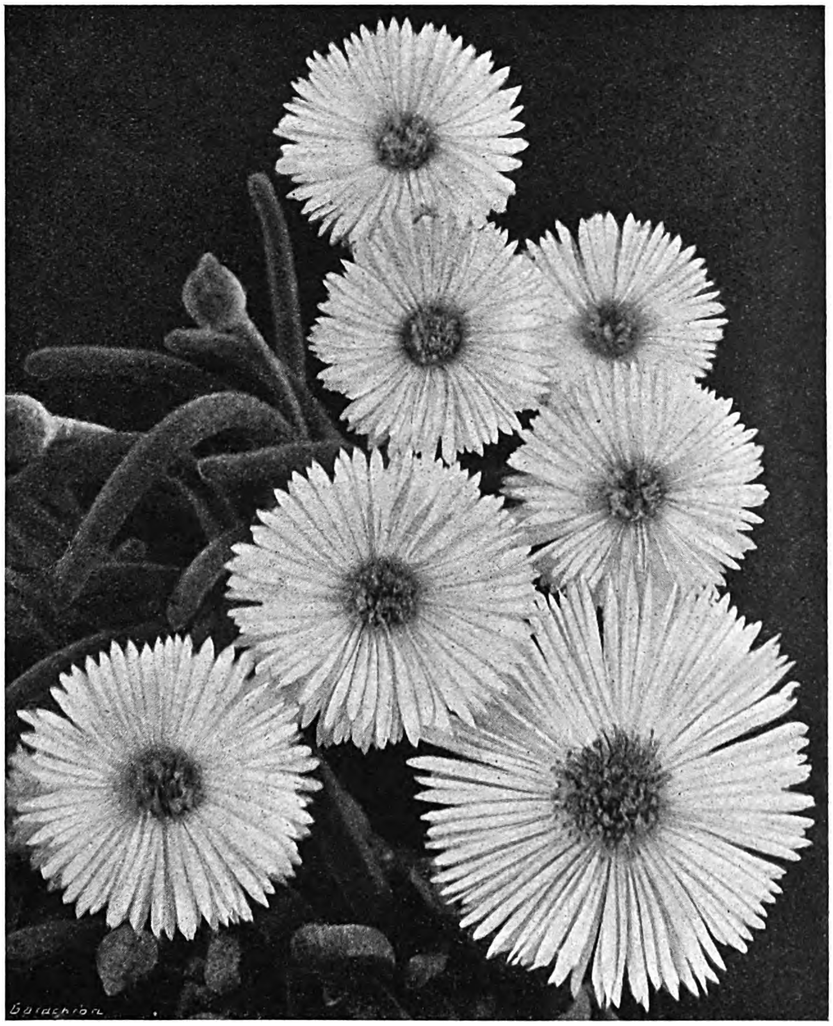

FIG. 19.—MONILARIA MONILIFORMIS.
Plant in flower; petals white and stamens yellow.

Much commoner was a straggly little epiphyte which flowers in the autumn and was almost in ripe fruit when I first met it on May 5. It had small, densely lepidote leaves, and flowers in heads of two or three. This also was a genuine epiphyte, although found so high as 10,000 feet; it belongs to the 'Maddeni' series, and has pink flowers. The fine, crocus-yellow 'Boothii' species described already was often met with as an epiphyte, although I first found it on rocks, where, indeed, it was infinitely more accessible.

Another common epiphyte opened its little jaundiced flowers in mid-June. It was quite one of the most miserable and, indeed, revolting Rhododendrons I have ever seen; sallow corolla, the lobes turned back to make it look even smaller than it was already, and dirty orange blobs—not just spots, but insanitary blisters—on the upper lobe. I collected seeds of this eye-sore in Burma in 1926, if not in Tibet in 1924, and plead not guilty; I had not seen it in flower. The foliage does nothing to correct the bad impression made by the flowers, until the autumn, when suddenly the previous year's leaves turn bright scarlet, almost redeeming the plant. There were two really delightful epiphytic species in the Delei valley, both of which, however, I had already met with and collected in the Seinghku valley, a yellow-flowered 'Boothii' and a white-flowered 'Edgeworthii'. The former flowered first in mid-May, and lasted until the middle of June at 11,000 feet or thereabouts. It is a bushy undershrub with yellow flowers, not particularly bright, and orange-brown anthers. The charm of the plant, however, lies in the foliage, the neat little leaves being dark green above and glaucous beneath, with scattered golden scales which glisten like flecks of mica. The neat, compact habit, without any loose ends, and the sharp contrast between the flowers—borne in no niggardly fashion—and the leaves, mark this out as a plant of distinction. It is just as much at home on the gneiss or granite cliffs, as on the Fir trees, Junipers and Larch. It forms its bulkiest bunches, perhaps, on the cliff faces, which catch a cascade of water from above, preferring the concrete water-laid-on shower bath to the vague abstractions of a saturated atmosphere. At first sight, this species might easily be mistaken for R. megeratum, the yellow flowers in their happy setting of electroplated leaves with bristly margins and petioles, reminding one of that plant. But it differs in one important respect; R. megeratum has solitary flowers, while in this plant they are nearly always in pairs. A minor distinction is that the capsule of this plant projects beyond the calyx, instead of being completely enclosed by it.

The 'Edgeworthii' did not flower until June—except at its lowest limit, where it flowered in the last week of May. Like the last, it grows on rocks as well as on trees, but its favourite haunt is certainly high up on some old dismasted Larch or Juniper, or Tsuga; across the glen you may see it swelling like a white cloud puff from some moss-bound tree stump, or clinging to the face of the cliff. The flowers are white, with a yellow spot near the base, irregularly banded and suffused with rose-purple on the reverse, often borne singly, usually in pairs, very rarely in threes; they are large, and bewitchingly fragrant. This delightful plant, which was very common on the ridge of Kaso, is easily distinguished from the other 'Edgeworthii' (already referred to as R. bullatum) by its much larger flowers, smaller leaves less woolly beneath, and calyx lepidote as well as hairy. The June rain played havoc with this fine plant, and its ruined corollas were strewn all along the track; but while it lasted it lit up the forest, and scented it, too.

These three true epiphytes, R. dendricola, the small-leafed 'Boothii,' and the 'Edgeworthii'—to say nothing of the "Crocus" 'Boothii'—are worth growing; but it is all Lombard Street to a China Orange that they will require protection. *F. Kingdon Ward.*

MESEMDRYANTHEMUM.

(*Continued from p. 84, Vol. LXXXV*).

MONILARIA, Schwant.

Dwarf, bushy, succulent plants, two to four inches high, with crowded, erect, stout branches, constricted at the nodes into short and often bead- or button-like joints. Leaves opposite, of two kinds, and only one pair of each kind produced annually; the first pair to appear when growth commences are rudimentary and sometimes scarcely more than a short, fleshy sheath, with its semi-circular lips closed together into a bag-like or globular body, but by the growth of the second pair of leaves the lips are pushed apart and remain surrounding the base of the joint formed by the second pair, which are long and nearly cylindrical, but more or less flattened on the upper side, and very shortly united at the base, papulose. Flowers solitary, terminal; pedicels long, papillate, with a pair of rudimentary leaves sheathing the base. Calyx papulose or papillate, unequally 5-lobed down to its union with the ovary, with the ovary-part shallow and convex beneath. Petals numerous, free, in 3–4 series, linear. Stamens numerous, erect in a column, or later becoming more or less loose; filaments not bearded at the base. Stigmas 5–7, stoutly ovoid-subulate, acute. Ovary inferior, shallow, 5–7-celled, with 5–7 sutural ridges on the flat top; placentas on the floor or outer wall of the cells. Capsule shallow, very shortly and broadly obconic, with 5–7 very prominent and thin sutural ridges on the flat top, and 5–7 valves and cells; valves reflexed or widely spreading; expanding keels more or less widely diverging, broad and flattish at the basal part, with the inner edges raised, and with narrow marginal wings; cells shallow, somewhat acutely roofed with membranous cell-wings; no placental tubercle. Seeds numerous in each cell, ovoid, pointed at one end, smooth.—Schwantes in *Gartenwelt*, 1929, p. 69.

Species 3; natives of Little Namaqualand and Van Rhynsdorp Division of South Africa; the type of the genus is M. moniliformis.

The name is derived from the Latin, *monile*, a necklace, in allusion to the manner in which the stems are constricted into bead-like joints.

The remarkable group of plants comprising this genus is among those I intimated in *The Gardeners' Chronicle*, 1925, Vol. LXXVIII, p. 412, that would probably have to be separated generically from Mesembryanthemum when better known. But as at that time I had not seen flowers or fruits of any species belonging to the group, I was unable to assign characters whereby to separate it; and previously I had associated the species with those now placed under the genus Mitrophyllum, in which I was at first followed by Schwantes, who enumerates the species under a section of that genus, but without a word of description by which it could be identified. Recently, however, he has separated it as a distinct genus, in which opinion I agree with him, for having been able during the past four years to study living plants in the adult and seedling stages of Monilaria and Mitrophyllum, I find they differ so conspicuously in vegetative characters, long pedicels, stout stigmas, and slightly in fruit, that I no longer hesitate to consider them as distinct genera, especially as Monilaria is easily distinguished from all its allies by the stems and leaves alone.

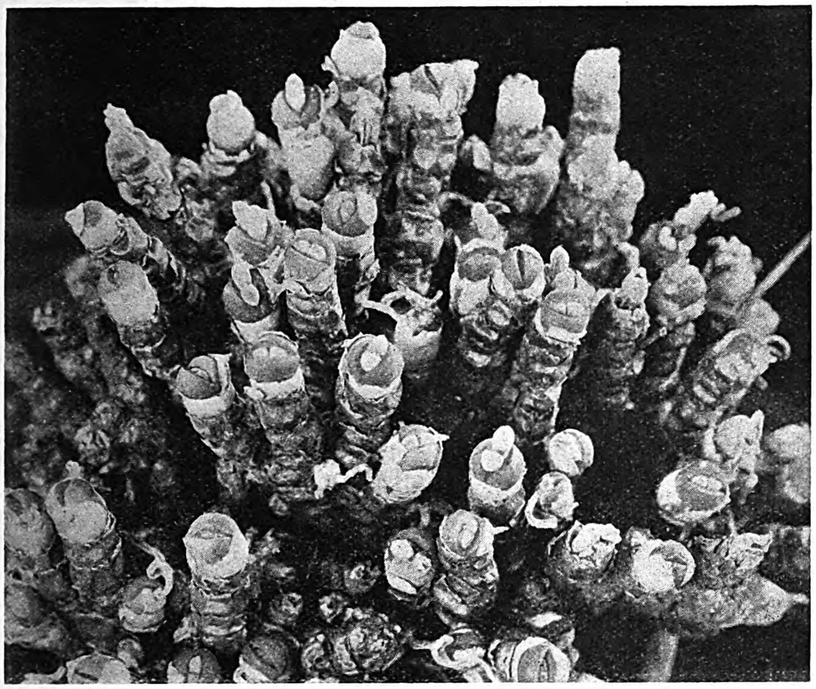

FIG. 20.—MONILARIA PISIFORMIS.
Plant at rest, natural size.

From Mitrophyllum it differs in its peculiar mode of growth, as follows :—The first of the two annual pairs of leaves is rudimentary, consisting of a pair of very short, fleshy, hemispherical lobes united at their base and at first closed together into a small hemispherical body (see Fig. 14, p. 29 of M. moniliformis commencing to vegetate), which become separated as the second pair of leaves develop. This second pair are long and sub-terete, and are but very shortly united into a sheath at the base above the short, bead-like internode from which they arise. This short sheath ultimately either decays or hardens into a short, free, cup-like, dark brown sheath terminating the internode and enclosing the next pair of rudimentary leaves, which ultimately disappear and leave the sheath surrounding the base of the internode above it, as is well seen in the stems of M. pisiformis and M. chrysoleuca. In Mitrophyllum the first pair of leaves are long, not sub-terete, and free except at the very base ; and the second pair are united into a long cone with free, leafy tips or short, blunt points.

The following are the first complete and illustrated descriptions of these very curious and interesting plants that have ever been published.

Key to the Species.

1. Joints of the stem twice or more than twice as thick as long, button-like or depressed-globose, not produced above into a short sheath, greyish ; petals white ; filaments and anthers yellow.
M. moniliformis.

2. Joints of the stem usually (but not always) as long as or longer than thick, more or less bead-like, produced above into a short sheath enclosing the base of the joint above it, smooth and hard, dark brown.
Joints of the stem ellipsoid or sub-globose ; petals stated to be yellow at the tips, then white, and pink at the base ; stamens with red filaments and yellow anthers.
M. pisiforme.

3. Joints of the stem somewhat compressed and obscurely 4-angled ; petals white ; filaments and anthers deep yellow.
M. chrysoleuca.

M. moniliformis, Schwant. in *Gartenwelt*, 1929, 69.—Plant much branched, 2–4 inches high when at rest ; branches erect, often crowded, 5-7 lines thick, constricted at the nodes, with short, depressed-globose or button-like joints, 1½–3½ lines long, greyish. Primary leaves 1½–2½ lines long, 4–6 lines broad and 2–3 lines thick, semi-circular in outline, with a minute point at the rounded apex, flat above, convex beneath, smooth, glabrous, not papulose, green. The second pair of leaves 2–3½ inches long, 2–2½ lines thick, slightly flattened on the upper side, very rounded on the back or sub-terete, obtuse, densely covered with minute, glittering papulae, somewhat bluish-green. Pedicels 2½–3 inches long, coarsely papillate. Calyx flattened at the base, coarsely papillate ; lobes 4–8 lines long, the outer 2½–3 lines broad, ovate, with leafy tips, the inner 3½–4½ lines broad, elliptic, with broad, membranous margins. Corolla 1½–2½ inches in diameter, opening between 11 and 12 a.m. and closing between 2 and 3 p.m. ; petals in about 3 series, 6–9 lines long, ½–1 line broad, linear, obtuse and more or less notched at the apex, pure white, shining. Stamens about 2 lines long, at first in a column, afterwards loosely separating ; filaments and anthers deep yellow. Stigmas 5, about 1 line long, stout, ovoid-subulate, acute, erect or ascending, yellowish. Ovary with 5 wing-like sutural ridges on the flat top, green. Capsule when closed about 7 lines in diameter and when expanded 10–11 lines in diameter, inner edges of the expanding-keels fringed with fine teeth. Seeds nearly ½-line long, pale brown with a darker brown point.

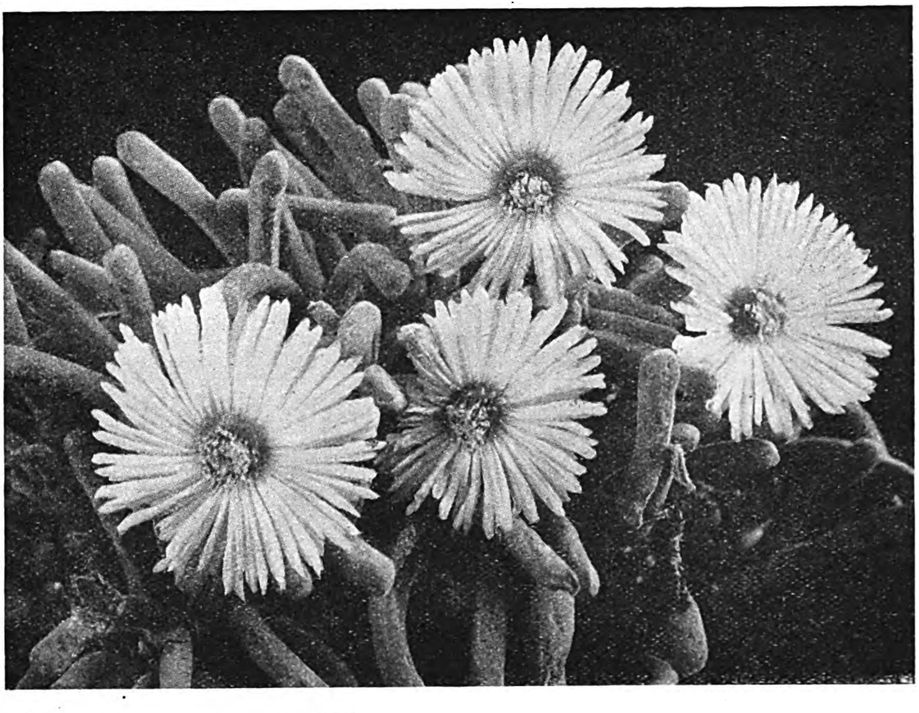

FIG. 21.—MONILARIA PISIFORMIS.
Plant in flower ; petals yellow, fading to white, and pink at the base ; stamens red.

Mesembryanthemum moniliforme, Thunb. in *Nov. Act. Acad. Leop.-Cur.-Ephem.*, Vol. VIII, Append, p. 7 (1791), *Prod.*, p. 88, and *Fl. Cap.*, ed. Schult., p. 413 ; Haw. in *Obs.*, p. 132 and 441, *Misc. Nat.*, p. 24, *Synop.* p. 207, and *Rev.*, p. 93 ; N. E. Br., in *Journ. Linn. Soc.*, Vol. XLV, p. 116, t. 5, f. 10 (drawn from memory), and in *Bothalia*, Vol. I, p. 158 ; Berger, *Mes. und Port.*, p. 56. Mitrophyllum moniliforme, Schwant. in *Zeitschr. f. Sukkulent*, 1926, p. 182. Conophyllum moniliforme, Schwant. in *Zeitschr. f. Sukkulent*, 1928, p. 322.

Van Rhynsdorp Division : On hills near Olifants River, towards the north, Thunberg ! Mrs. E. Rood !

This curious plant was introduced into Kew Gardens by Masson in 1794, but appears to have soon died out. The above description was made from living plants and withered flowers sent to me by Mrs. E. Rood, for Thunberg's type is both leafless and flowerless, having been collected when in a state of rest. The illustrations are from photographs kindly sent to me by Mr. T. N. Leslie. Fig. 14 represents the plant just commencing to grow after a period of rest, and Fig. 19 the same plant when in flower.

M. pisiformis, Schwant. in *Gartenwelt*, 1929, 69.—Plant compactly much branched, 2½–4 inches high when at rest and leafless. Branches erect, 3–4½ lines thick, constricted at the nodes into bead-like, subglobose or ellipsoid joints, varying from 2–5 lines long, glabrous, smooth, brown or greyish-brown. Primary leaves 2–3 lines long, 3–4 lines broad, semi-circular in outline, flat above, convex beneath, glabrous, smooth, green. The second pair of leaves 1–3 inches long, 2–2½ lines thick, sub-terete, slightly flattened on the upper side, very rounded on the back, very obtuse, minutely papulose and glittering, green. Pedicels 2–3 inches long, papillate. Calyx coarsely papillate; lobes 4–8 lines long; the outer ovate at the base, with leaf-like tips; the inner elliptic or elliptic-ovate, with broad, sub-membranous margins. Corolla 1¼–1½ inch in diameter, open in the afternoon; petals in about 3 series, 7–8 lines long, linear, acute, obtuse or slightly toothed at the apex, they are stated to be "top yellow, then white, then pink." Stamens about 2 lines long; filaments red; anthers yellow. Stigmas 5–6, about 1 line long, erectly spreading, stout, ovoid-subulate, acuminate, yellow. Ovary with 5–6 wing-like sutural ridges on the flattened top. Capsule 4½–6 lines in diameter and 2 lines deep when closed, 6½–8 lines in diameter when expanded; inner edges of expanding-keels entire. Seeds about ¼-line long, pale brown with a darker brown point.

Mesembryanthemum pisiforme, Haw. in *Misc. Nat.*, p. 23, *Synop.*, p. 206, and *Rev.*, p. 93; Berger in *Mes. und. Port.*, p. 56. Mitrophyllum pisiforme, Schwant. in *Zeitschr. f. Sukkulent*, 1926, p. 182. Conophyllum pisiforme, Schwant. in *Zeitschr. f. Sukkulent*, 1928, p. 322.

Van Rhynsdorp Division: Van Rhynsdorp Karoo, Mrs. E. Rood!

Described from living plants, which I owe to the kindness of Mrs. Rood. It differs from M. moniliformis by its brown (not greyish) stems, rather smaller flowers, with the petals less crowded, and the red filaments of the stamens. The figures are from photographs sent to me by Mr. T. N. Leslie. Fig. 20 represents the plant at rest, and Fig. 21 when in flower.

M. chrysoleuca, Schwant. in *Gartenwelt*, 1929, p. 69.—Plant 3-4 inches high, compactly branched. Branches [compressed and obscurely 4-angled, 4–6 lines broad and 3–4 lines thick], with joints 2–4 lines long, each old joint with a hard and somewhat rigid, dark brown skin or adherent sheath having its upper part free and forming a cup-like sheath surrounding the base of the joint above it. Primary pair of leaves about 1½–2 lines long, [fleshy and somewhat hemispherical when alive, united into one body for half of their length and closed together]; from between them the second pair emerges, borne on a short, compressed joint or internode; these leaves are 2–3 inches long and 2–2½ lines thick, sub-terete, slightly channelled or flattened on the face, obtuse, papulose. Pedicels 2–3 inches long, papulose. Calyx papulose, the longer lobes 6–7 lines long, lanceolate or oblong-lanceolate, obtuse, and the shorter lobes about 4 lines long, with broad, membranous margins. Corolla about 1½ inch in diameter; petals in 3–4 series, 7–8 lines long, ½–1 line broad, cuneately linear, acute, obtuse or slightly toothed at the apex, white. Stamens about 2–2½ lines long; filaments and anthers of a rich deep yellow. Stigmas 5, about 1–1½ line long, stoutly subulate. Fruit not seen.

Mesembryanthemum chrysoleucum, Schlechter in *Engl. Bot. Juhrb.*, Vol. XXVII, p. 126 (1899); Berger in *Mes. und Port.*, p. 56. M. scutatum, L. Bol. in *Ann. Bot. Herb.*, IV., p. 73 (1927), in *S. Afr. Gard.*, 1928, p. 127 and p. 126, f. 4. and in *Mes.*, p. 59, f. 4 and 60, with Fig. Mitrophyllum chrysoleucum, Schwant. in *Zeitschr. f. Sukkul.*, 1926, p. 182. Conophyllum chrysoleucum, Schwant. and C. scutatum, Schwant., in *Zeitschr. f. Sukkul.*, 1928, p. 322. Monilaria scutata, Schwant. in *Gartenwelt*, 1929, p. 69.

Van Rhynsdorp Division: Karee Bergen, Schlechter 8,292! Little Namaqualand: near Walle Kraal, Pillans 17,794!

I am indebted to Mr. T. N. Leslie for a living plant, flowers and photographs of this interesting species. Mr. Leslie's plant, here figured, was received from Mr. Pillans and is his No. 17,794, which has been described by Mrs. Bolus as Mesembryanthemum scutatum, but I am unable to distinguish it in any way from M. chrysoleucum. The words in the description that are between square brackets [] are from this living plant, but all the rest of the description is made from a type specimen of M.chrysoleucum, which has been so crushed in pressing that the stem and leaves do not show their true form. Fig.12 p.25 represents the plant just commencing to produce its leaves, and Fig. 13 p. 27 the same plant when in flower. *N. E. Brown.*

(*To be continued*).

THE GENUS PRIMULA.

(*Continued from p.* 10).

OVALIFOLIA (Franch.). Oval-leaved P. (Petiolaris-Davidii.)

THIS herbaceous, perennial species produces a tuft of thin or somewhat leathery, oval, blunt leaves three to four inches long, gradually, or abruptly contracted into a stalk equalling, or shorter than, the blade in length; margins furnished with regular, rounded, or nearly entire, ciliate teeth; both surfaces and the stalks more or less clothed with minute, rust-coloured hairs. Flower stem one-and-a-half-inch to six inches tall, covered with rust-coloured hairs, and bearing at its apex an umbel of purple flowers. Corolla concave, about one inch across; lobes egg-shaped, slightly notched; tube funnel-shaped, longer than the calyx. In cultivation in 1906.

Grows in alpine pastures on the mountains of Yunnan, near Mupin, and also on those in the province of Hupeh and near Mongtz, central Szechuan, China.

Culture: As for P. Davidii.

OXYGRAPHIDIFOLIA (W. W. Sm.) Sponge P. (Farinosae.)

This dwarf species possesses a slender rootstock which is clothed at its crown with the remains of previous seasons' foliage, which form a conspicuous white, sponge-like mass. The smooth, non-mealy leaves, produced in rosettes, are about half-an-inch long with blades varying from almost orbicular to lance-shaped; they are blunt or rounded at the tip, abruptly or gradually narrowed into a winged stalk somewhat dilated at the base; margins entire, or furnished with from one to three teeth; upper surface deep green, underside olive-green. Flower stem about two inches tall, axillary, bearing a solitary mauve flower with a pale yellow eye, or lavender-blue with a grey eye. Corolla nearly three-quarters-of-an-inch across, more or less flat, with broadly heart-shaped, deeply notched lobes; tube cylindrical, dilated upwards, about half-an-inch long, with a distinct ring in the throat. Flowers in June and July.

Grows in crevices and on ledges of limestone cliffs, also in open, moist, stony alpine pastures, on the mountains around Muli, in south-western feet Szechuan, at 12,000 feet to 15,000 feet above sea-level.

Culture: Fibrous loam, peat and limestone chips in an open, moist position, with protection from damp in winter, should suit it.

PALINURI (Petagna). Italian Cowslip. (Auricula-Euauricula).

This species has a stout rootstock, which, when aged, produces masses of thick, woody stems on, or just below, the surface of the soil, and resembling those of a German Iris. The tufts of rather fleshy, light green leaves have oblong or oval, blunt blades, tapering to a long, or short stalk, in all two inches to eight inches long; margins cartilaginous and furnished with sharp teeth; both surfaces more or less smooth, except on the margins, where there are minute, glandular hairs. Flower stem three inches to ten inches tall, mealy upwards, and bearing a one-sided umbel of from ten to forty nodding, fragrant, Cowslip-like flowers. Corolla yellow, half- to five-eighths-of-an-inch across, campanulate, divided into five oval, slightly notched lobes with incurved margins; tube funnel-shaped, about half-an-inch long. Flowers from February to August. *Bot. Mag.*, t. 3,414; *Gard. Chron.*, Vol. LVI, p. 217, fig. 87. In cultivation in 1816.

Grows in clefts in rocks at 1,000 feet above sea level and in sand on the sea-shore, in one or two localities in the Province of Salerno, in southern Italy.

Culture: It flourishes in good, calcareous loam and sand, in sun or shade; it also succeeds in a cleft in a limestone rock, packed with the above compost. It is quite hardy when once established, but does not blossom freely until it has reached a considerable size. *A. W. Darnell.*

(*To be continued*).

VEGETABLE GARDEN.

SPRING CABBAGES.

DURING the last winter many thousands of Cabbage plants were lost and it was disappointing to see so many thin Cabbage beds during the spring when vegetables were so scarce. It may seem rather an unimportant subject, but where large supplies of vegetables have to be maintained the loss of a bed of spring Cabbages is disastrous, as crop should fill the gap between the ordinary supplies and the choicer vegetables, such as Peas, Beans, Cauliflower, etc., especially in the North of England, where soils and climate are so much colder. Generally, very little trouble is taken with such a commonplace vegetable, the seeds being sown according to the district, and the seedlings in due course planted out from the seed beds; in many cases, this practice answers admirably, but in others it proves disastrous if really bad weather prevails during the ensuing winter.

I have found that in this particular area and with the heavy cold soil I have to deal with, it is essential to prick out the young seedlings from the seed bed so soon as large enough, into nursery beds in rows nine inches apart, allowing three or four inches between each plant; in this way the plants develop into good, strong, sturdy specimens, with hard stems which defy the slugs and frost and come through the winter such as the last with no bad results. The illustration (Fig. 22) shows a bed of 5,000 spring Cabbages, mostly of Sutton's Harbinger, a week after cutting had commenced, and well demonstrates the value of the above method of cultivation.

The first sowing of Harbinger was made on July 20, followed by further sowings during August, the resultant plants eventually being planted after Onions, the ground being cleaned and cultivated to a depth of four inches, just sufficient for planting; no soil was drawn up to the stems until the hard frosts of the spring had departed, as the soil was always too wet.

As there were so many disappointments during last spring among Brassicas, I offer these suggestions as a means of defeating the weather where there is any difficulty in bringing the plants safely through the winter.

Another good method which is always advisable is to prick out the later and the later-sown plants into skeleton frames, which may be protected, as these make an admirable succession to the early crop. There are many good strains of Cabbage, but for quality and earliness I have yet to find one to beat Sutton's Harbinger, and in the bed depicted only ten ran to seed. If a true stock of Ellam's Early can be procured it is also one of the finest Cabbages to grow, followed by Sutton's April, and Flower of Spring; but, as in all vegetables, strain is important. *A. Falconer, Cheadle Royal.*

SOCIETIES.

ROYAL HORTICULTURAL.

July 9.—Although this was the occasion of the Amateurs' Flower Show, the Floral and Orchid Committees met, but had very little work to do. The judges were the busy people, and their duties were unusually heavy, by reason of the extent of the show, the keenness of the competition, and the fine quality of the exhibits throughout. This was certainly by far the best of the several Amateurs' Shows yet held, and the veteran Mr. H. B. May—to whom the inception of such shows is due—must have been satisfied that his scheme, carried into effect, has at last been thoroughly justified by results.

The flowering shrubs, the Orchids, stove and greenhouse plants, and the hardy border plants were particularly effective and interesting, but Lilies, Sweet Peas, Roses, Carnations, bulbous plants, annual flowers and Delphiniums all added their quota of beauty and interest.

Orchid Committee.

Present: Sir Jeremiah Colman (in the chair), Mr. Gurney Wilson (Hon. Sec.), Prince Shimadzu, Mr. Fred J. Hanbury, Mr. T. Armstrong, Mr. Charles H. Curtis, Mr. A. Dye, Mr. S. Flory, Mr. H. H. Smith, Mr. Fred K. Sander, Mr. H. G. Alexander and Mr. J. Cowan.

There were few members present, and only four plants presented for consideration. No awards were made, and exhibitors, as usual, complained of the dead white background of the walls in the Committee Room; a screen of neutral colour would provide a background suitable for Orchids, and one long overdue. Sir Jeremiah made a kindly reference to the passing of Mr. Ballantine, who was a member of the Committee very many years ago; the Committee agreed that a letter of sympathy be sent by the Hon. Secretary to Mr. Ballantine's family.

Floral Committee.

Present: Section A.—Mr. Henry B. May (in the chair), Mr. J. B. Riding, Mr. W. B. Gingell, Mr. D. B. Crane, Mr. H. R. Darlington, Mrs. Helen Lindsay Smith, Mr. A. E. Vasey, Mr. J. T. West, Mr. C. F. Langdon, Rev. Rollo Meyer, Mrs. Ethel Wightman, Mr. Arthur Turner, Mr. George Churcher, Mr. J. F. McLeod, and Mr. W. D. Cartwright (Secretary).

No awards were made by this section of the Committee.

Present: Section B.—Mr. C. T. Musgrave (in the chair), Mr. F. C. Stern, Mr. F. G. Preston, Mr. G. Yeld, Mr. Hiatt C. Baker, Mr. Mark Fenwick, Lady Beatrix Stanley, Mr. W. B. Cranfield, Mr. C. Williams, Mr. T. Hay, Sir William Lawrence, Mr. Gerald W. Loder, Mr. E. A. Bowles, Mr. A. Bedford, Mr. James Hudson, Mr. Amos Perry, Mr. G. Reuthe, Mr. W. J. Bean, the Marquis of Hartington, Mr. T. W. Taylor, Mr. L. R. Russell and Mr. N. K. Gould (Secretary).

AWARDS OF MERIT

Cyananthus Farreri—A lowly plant with mossy growth and leaves, resembling some Saxifrages. The flowers are terminal and solitary, at the ends of the new growths; they are deep rich violet-blue with a brown, hairy calyx. The species is from Tibet, and was shown as suitable for flowering in an alpine house. Shown by Lady Aberconway and the Hon. H. D. McLaren (gr. Mr. F. C. Puddle), Bodnant.

Circium occidentale var. Coulteri.—This Californian Thistle (Fig. 11, see also p. 28) flowers in the second year from seed-sowing; it has silvery-white leaves and stems, and a flower head consisting chiefly of stamens of varying lengths, the lower ones being of rich cerise-red shade that is almost scarlet when the partly opened heads are seen in bright sunshine. The involucre is spiny, silvery-grey and webbed with fine cotton-wool. Shown by Mr. T. Hay, Hyde Park.

Aster adfinis.—A charmingly pretty South African, half-hardy annual plant, almost eight inches high when in flower, bearing numerous rich blue flower heads, each with a disk of yellow florets and anthers. The ray florets are almost three-quarters-of-an-inch to an inch in length, narrow, and set well apart, so that a flowering specimen is quite graceful. The plant has a lowly branching habit, and the linear leaves are soft green. It is probably identical with Felicia adfinis. Shown by Messrs. Sutton and Sons.

Competitive.

ORCHIDS AND STOVE AND GREENHOUSE PLANTS.

The premier award for a group of Orchids arranged on a space twelve feet by four-and-a-half feet, was won by Lionel de Rothschild, Esq. (Orchid grower, Mr. B. Hills), Exbury, Southampton, with a very bright display wherein Dendrobium thyrsiflorum and brilliant Odontiodas formed the central feature. On either side excellent plants of various Miltonias were grouped in front of Cattleya gigas, C. Martinetti, C. Bletchely Prince, C. Falco and C. Mossiae. The best of the Miltonias were M. vexillaria var. Snowflake, M. v. var. Constance Wigan, M. Greta, M. J. Gurney Fowler, M. Lyoth, M. gattonensis, M. Kennie var. Aladdin and M. Charlesworthii. A few Odontoglossums and Epidendrum vitellinum majus were also shown. The second prize fell to Mrs. Carl Holmes (gr. Mr. W. J. Penton), The Node, Welwyn, who also had a fine group in which Miltonias figured largely, together with Phalaenopsis Rimestadiana, Cypripedium bellatulum, C. niveum, C. Curtisii var. Sanderae, Anguloa Cliftonii, Cattleya Harold var. alba, and several small plants of Miltonia St. André and M. William Pitt. Third prize was awarded to J. J. Joicey, Esq. (gr. Mr. J. Mackay), The Hill, Witley, Surrey, whose outstanding plants were of Dendrobium thyrsiflorum, Brasso-Laelio-Cattleya Witleyensis, Coelogyne Dayana and Cypripedium St. Swithin.

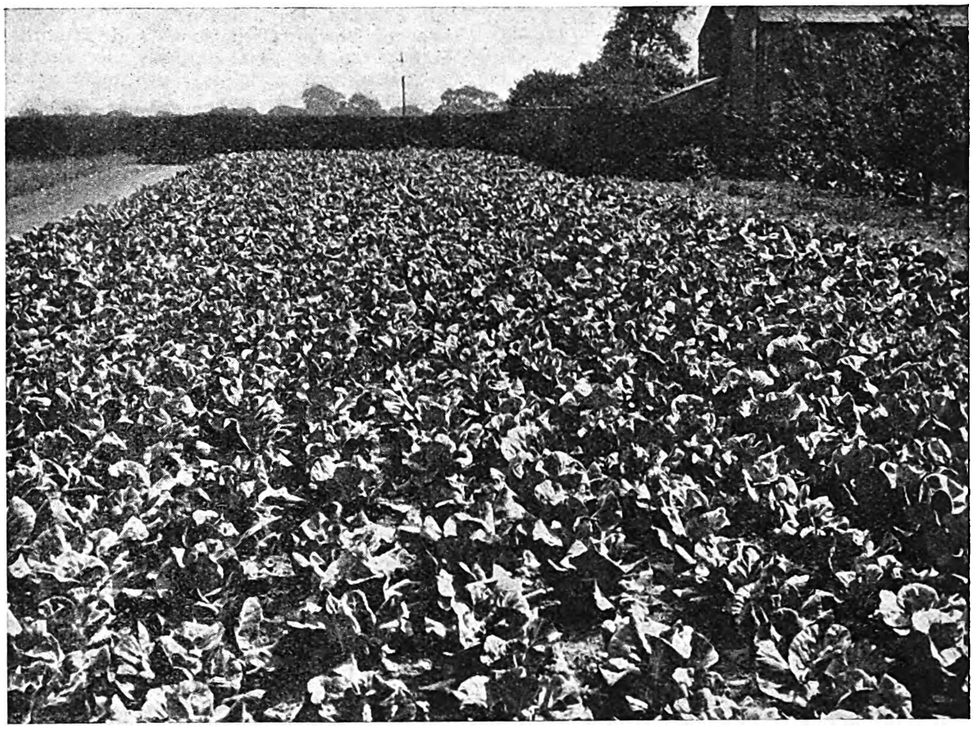

FIG. 22.—CABBAGE HARBINGER.
A bed of 5,000 plants at Cheadle Royal; Spring, 1929 (see p. 34).

Mr. Lionel de Rothschild was also placed first for a dozen Orchids, and in this class he showed Miltonia Lena, Dendrobium acuminatum, Cattleya Mendelii var. Stuart Low, Oncidium crispum, Brassavola Digbyana, Lycaste cruenta var. majus, Odontioda Etna, Odontoglossum Gorizia var. Perfecta, Thunia Winniana, Cypripedium Forest King and Cochlioda Noezliana, all in good condition. Second, Mrs. Carl Holmes, whose Dendrobium acuminatum, Epidendrum prismatocarpum and Brassia verrucosa were very good; third, F. J. Hanbury, Esq. (gr. Mr. Farnes), Brockhurst, East Grinstead.

In the division open only to amateurs who employ no more than one gardener and a boy, or a part-time man, a class was provided for three Orchids. There was but one entry and this consisted of Phalaenopsis Parishii, Lycaste cruenta and Vanda suavis, the last carrying a pair of spikes. A first prize was awarded to A. M. Gentle, Esq. (gr. Mr. B. Waller), Church Crescent, St. Albans, for this exhibit.

The groups of flowering plants, arranged against the wall, were all handsome arrangements. The first prize was won by Lionel de Rothschild, Esq. (gr. Mr. A. Bedford), Exbury, Southampton, with a magnificent group which included a representative variety of Anthuriums, Hippeastrums, Hydrangeas, tall bushes of Gardenias well set with flowers, Himalayan Rhododendrons, greenhouse Carnations and Clivias. All the plants illustrated first-rate cultivation, and they were arranged tastefully. The second prize group of A. P. Brandt, Esq. (gr. Mr. J. W. Barks), Bletchley Castle, Bletchley, contained many superb Codiaeums (Crotons), but it lacked the variety of the first prize group, and the arrangement, although dignified was a trifle more formal. J. Sanders, Esq, (gr. Mr. W. E. Pullen), Millbrook, Chigwell was awarded the third prize for a quiet, restful group of Caladiums and other foliage plants, with a couple of Orchids and a Bromeliad in flower. Sir William Lawrence, Bart. (gr. Mr. Everatt), Burford, Dorking, was fourth.

In the class for six pots and pans of alpines the first prize was won by Mark Fenwick, Esq. (gr. Mr. F. Tustin), Abbotswood, Stow-in-the-Wold, who included good pans of Saxifraga cochlearis minor, Campanula Mrs. Payne and Leontopodium alpinum. Samuel Wallrock, Esq. (gr. Mr. W. H. Holloway), The Manor House, Stanmore, was second, with an interesting collection which included good plants of Campanula W. H. Payne and Androsace lanuginosa var. Leichtlini. Colonel Stephenson Clarke, C.B. (gr. Mr. W. Fleming), Borde Hill, Haywards Heath, was first in the class for one alpine with a good example of Petrocosmea nervosa, and Sir William Lawrence, Bart., was second with Monardella macrantha.

The best collection of four vases of Antirrhinums was shown by Mrs. Hamilton (gr. Mr.

W. Smith), Kingshead, Claygate. The first and second prize collections of six tuberous Begonias were very meritorious. Double-flowered varieties were shown, and the prize-winners were T. Crawford, Esq. (gr. Mr. J. Whiting), Whitehall, Bristol, and Lady Carr (gr. Mr. J. T. Doe), Walton-on-the-Hill, in the order named. The Gloxinias also showed excellent cultivation. Lady Carr won the first prize with six splendid plants, and C. H. Watkins, Esq., Muswell Hill, was second. J. H. Jenkins, Esq. (gr. Mr. W. Dennis), Kenley, Surrey, was first with six exceedingly good Fuchsias, and Sir William Lawrence, Bart., was a good second.

There were three very interesting exhibits of spikes of six distinct bulbous plants. The first prize was won by Sir William Lawrence, Bart., with Ismene Sulphur Queen, Eucharis Burfordiensis, Pancratium speciosum, Dierama pulcherrima, Zephyranthis vericunda and Iris Anglica. Lionel de Rothschild, Esq., had a spike of Crinum Poweli alba and a bunch of Cyclamen europeum in his second prize exhibit

The first prize for six foliage plants in pots was awarded to H. W. Henderson, Esq. (gr. Mr. F. L. Pike), West Woodhay, Newbury, for half-a-dozen splendid Codiaeums. A. P. Brandt, Esq., was second, with a variety of well-grown specimens. H. E. Chubb, Esq. (gr. Mr. W. J. Drew), Chorley Wood, was first with six exceedingly good plants of Streptocarpus. There were three interesting little collections of Succulents and the first prize collection of H. J. Harrison, Esq., New Cross, London, included a good variety. F. Davidson, Esq., Exeter Road, N.W., was second.

Lionel de Rothschild, Esq., was easily first in the class for nine flowering plants, where he had Hoya carnosa, Rhododendron Monarch and a good Hippeastrum seedling. Sir William Lawrence showed Eustoma Russelliana and Attaca cristata in his second prize exhibit. Lionel de Rothschild, Esq., was the only exhibitor of a group of greenhouse flowering plants of one genus, and he was awarded the first prize for an excellent arrangement of very good Carnations.

E. H. Atkin, Esq., Muswell Hill, was awarded the first prize for a pleasing group of miscellaneous plants in Class 81.

The various classes for Ferns were not quite so well contested as in former years, but very good plants were staged. C. W. Mander, Esq., Chorley Wood, was awarded the first prizes for twelve Ferns in pots and for a similar number of British Ferns in pots or pans. He had very good specimens, and his greenhouse Ferns, included useful varieties of Adiantum, Nephrolepis, Pteris and other genera. His British specimens were good forms of Lathraea, Osmunda, Polypodium and Scolopendrium. J. H. Jenkin, Esq., Kenley, showing varieties of Adiantum, Pteris and Asplenium, was first with six greenhouse Ferns, and C. Henwood, Esq., Brondesbury, London, had a similar number of very fine British Ferns, while C. Luckin, Esq., East Grinstead, was awarded first prizes for three plants each of greenhouse Ferns and of British Ferns.

In the principal classes the Sweet Peas were of even better quality than at the recent show of the National Sweet Pea Society. There were seven especially fine collections of twelve vases of distinct varieties, and Mrs. Wigan (gr. Mr. F. W. Cotterell), Danbury Park, Chelmsford, who won the first prize and the N.S.P.S. Silver-gilt Medal, had superb vases of Youth, Purple Monarch, Grenadier, Gleneagles, Ivory Picture, Magnet, Powerscourt, Mrs. A. Searles, Sunkist, Chieftain, Avalanche and Flamingo. F. W. Franks, Esq. (gr. Mr. W. Humphrey), Loampits, Tonbridge, was a very good second, and he had splendid vases of Hero, Glorious, Wild Rose and Royal Pink. Major C. B. Krabbe (gr. Mr. A. W. Gower), Calcot Grange, Reading, was third in this strong class. William Huffey. Esq. Boormans, Tonbridge, won the first prize with six vases of Sweet Peas for the third year in succession. He showed magnificent vases of Royal Pink, Powerscourt, Mammoth, Youth, Royal Sovereign and Pentore. G. Holder, Esq., Oxted, Surrey, was second.

Roses did not quite reach the high standard of the Sweet Peas, though several very attractive exhibits were staged. Mrs. E. M. Wightman won the first prize for six Polyantha varieties, with a good selection which included Golden Salmon, Ellen Poulsen and Else Poulsen. The best six vases of rambler Roses, shown by Mrs. Tibley, Northwood, included well-flowered sprays of Erecta, Alberic Barbier, Blush Rambler, and American Pillar. H. E. Cribb, Esq., had the best six vases of Single Roses, and his vases of Silver Moon, F. Mitten and American Pillar were exceptionally good. In the class for twelve vases of Tea or H.T. varieties, the chief prize was won by E. H. Pleasance, Esq., Cambridge, with an admirable exhibit in which the best were Shot Silk, Avoca, Lady Dixon Hartland and Margaret McGreedy. Mr. G. A. Hammond, Burgess Hill, was second, and his best vases were of Mrs. C. V. Haworth and Mrs. A. R. Barraclough. In Division B., Mrs. E. M. Wightman won the first prize for three vases of dwarf Polyantha varieties, and included particularly good sprays of Coral Cluster and Else Poulsen. Mrs. Torkington, Maidenhead, showing Paul's Scarlet Climber and other useful sorts, was first with three vases of Pillar Roses. In Division C., Mrs. Stuckey, Billericay, had the best vase of one variety, and C. Norman, Esq., Wembley Park, was first with three vases of Tea or H.T. varieties.

J. Fairlie, Esq., Acton, was first with six vases of border Carnations, and Lionel de Rothschild, Esq., was similarly successful with the greenhouse varieties, both showing very good blooms.

Mrs. Emmott (gr. Mr. P. Sherlock), Reigate, won the first prize with twelve vases of very good annuals, which included Ten-week Stocks, White Spiral Candytuft and Clarkias. Sir William Lawrence, Bart., was second. Delphiniums filled a long stretch of tabling and made a fine display. The best twelve vases was shown by Mrs. Hamilton, who had a pleasant variety of good spikes. Mrs. Emmott was a good second. The exhibits of six vases were of equally good quality, and the first prize vases of R. Morton, Esq., Woodside Park, London, were very pleasing. Mr. A. J. Weeks, Limpsfield, was a very close second. L. D. Corder, Esq., Bromley, had the best three vases of Delphiniums.

The many exhibits of cut sprays f hardy shrubs in flower made a fine display and attracted a deal of well-merited attention. Lionel de Rothschild, Esq., had the best twelve vases in which he included very floriferous sprays of Magnolia macrophylla, Azalea optima, Buddleia alternifolia and Zenobia speciosa. Gerald W. E. Loder, Esq., Wakehurst Place, Ardingley, Sussex, was a close second, and his chief shrubs were Rhododendron discolor, Lonicera tragophylla, Kalmia latifolia, Stewartia chineniss and Magnolia parviflora. Colonel Stephenson R. Clarke was third in this large class. Mrs. A. Desborough, Broadstairs, won the first prize with six vases of hardy flowering shrubs. The chief sorts were Desfontania spinosa, Embothrium coccineum and Abutilon vitifolium. Lord Woolavington (gr. Mr. E. W. Fuller), Lavington Park, Petworth, was second, with well-flowered sprays of hardier subjects. In Division B., the best six vases were staged by Mrs. Torkington, Maidenhead, who had good vases of Phlomis fruticosa and Escallonia rosea. Mrs. E. M. Wightman was second.

FÉDÉRATION HORTICOLE PROFESSIONELLE INTERNATIONALE.

The Annual Conference of this Federation was to have been held in London at the time of the Chelsea Show, but as that period proved unsuitable to the French delegates, the Conference was postponed until July 3, when it opened under the Presidency of Mr. G. W. Leak, in the Royal Horticultural Society's Lecture Hall, kindly lent for the purpose.

About seventy delegates were present, representing England, France, Belgium, Holland, Germany, Switzerland and Italy, and after a vote had been taken, Poland was also admitted.

Mr. Leak welcomed the foreign delegates, and said that although the Conferences sometimes failed to do all that was hoped, they were justified because of the opportunity, afforded for the creation of friendships among commercial horticulturists of many nations, and the discussion of questions of mutual interest; in short, the Conference was a kind of Horticultural League of Nations, and as such deserved support. Baron Cartier, the Belgian Ambassador, was present to show the interest his nation takes in the annual international gatherings, and he also made a kindly speech in which he emphasised the value of such meetings, because more could be done by personal discussion than by many letters.

M. Chas. Pynaert, Mr. Schetelig and Mr. Krelage were appointed Vice-Presidents, Poland was admitted, and the Minutes and Report of the Ghent Conference of 1928 were adopted as printed and circulated. M. Sauvage, the Treasurer, was unavoidably absent, for the first time since 1919; his accounts were adopted subject to audit, and a telegram of sympathy was sent to the veteran florist. The accounts showed an expenditure of 5,951 francs on printing and a credit balance of 3,662 francs.

M. Turbat who was subsequently re-elected General Secretary, pointed out that the work was now so heavy, and he was so busy (he is Mayor of Orleans, as well as head of a nursery business), that he needed paid clerical assistance. A very long discussion ensued, and a desire was expressed for a condensed report or a typed one for each nationality, as a means of reducing expenses on printing, and thus providing money for clerical assistance. M. Turbat, however, would not agree to the curtailment of the printed report of Conference proceedings, and even stated that unless the annual report was published in the usual way, he could not see his way to retain the position of Secretary. The matter was shelved to a further sitting of the Conference, but when it was again brought up M. Turbat was still obdurate, and so the Conference let him have his own way, and agreed that each nationality should increase its annual subscription to meet the increased expenditure.

Regarding the Bureau of Plant Registration, it was agreed that everything possible should be done to protect the raisers of novelties, but legislation appeared unable to meet the needs, although a proposal before the French Senate seemed to be an advance on previous suggestions. The Conference approved the French proposals, and hoped the new law, if adopted, would protect raisers and give them rights in the novelties they produced. It was left to each nationality to suggest to its own government a plan of protection for raisers of new plants. Some delegates considered such legal protection would be of little use owing to the difficulties of identification. Against this, it was considered that legal protective machinery should be evolved, even if raisers did not choose to take advantage of it; moreover, the certificates of recognised horticultural societies, and the descriptions published of Certificated plants, fruits and vegetables would provide a means of identification in cases of disputed rights.

The discussion was continued at some length, and eventually it was agreed to explore the possibilities of legal action in each country represented, and to form a special committee to report progress at the Conference in 1930. The Committee appointed consists of Mr. Edward Laxton (Britain, Secretary), M. Rène Barbier (France), M. Emile Praet (Belgium), M. Krelage (Holland), Mr. Blossfield (Germany), M. Bertsch (Switzerland), Dr. Sgaravatt (Italy) and M. Machlejd (Poland).

Arrangements were made for the holding of various Committee meetings between the delegates of certain countries for the elucidation of specific matters. The general reports on the condition of horticultural trade were taken as read. Questions of international transport, packing and over production did not occupy much time.

The only alteration of the statutes suggested was one to admit landscape gardeners and retail florists. As neither of these classes of horticulturists were regarded as "producers" the question of their admission was left over until next year, so that delegates could consider the position of the F.H.P.I. in regard to these sections of the horticultural trade.

The Conference then adjourned until the next day.

The second session (Thursday, July 4) opened shortly after 10 a.m., when phytopathological questions were discussed, and also the creation of an International Phytopathological Bureau. The Conference was agreed, as on a previous occasion, that an international form of certificate of health for plants should be instituted, and if signed by a competent authority, should secure the admission of the plants it accompanies into any country. Mr. Krelage gave a report of the diplomatic Conference for the protection of plants, held in Rome last April, and said that the final text of the convention was quite acceptable from the point of view of international trade. It guarantees the security of crops, and the rights of any country to defend itself against pests, but expressly states that the interests of international trade should be borne in mind. It agrees that cereals, fruits, vegetables, cut flowers and perishable subjects should not, in general, need a health certificate from the deporting countries and, further, that health certificates for plants should not be made use of as a form of prohibition. At the F.H.P.I. Conference of 1928, the view was expressed that horticulturists should be represented at the Rome Convention; Belgium and Holland sent delegates, but Britain was not represented. This omission was due to the fact that the original proposals made by the International Agricultural Institute could not be approved by the British Government but, as Mr. Krelage pointed out, the final text is so different from the first that there is good reason to believe that the motive for not becoming a signatory to the convention no longer exists, and he hoped the British delegates to the F.H.P.I. would study the matter and recommend their Government to sign.

Mr. Krelage was heartily thanked on behalf of the Conference by M. Pynaert and Mr. C. H. Curtis, the latter at the same time giving a précis of the basis of discussion on phytopathological questions which will take place at the meeting of the British Association at Cape Town on July 26.

Various reports were presented but not discussed, and some items dealt with on the previous day came up for further consideration.

The rest of the morning—and there was not much time left—was devoted to the interesting subject of Plant Nomenclature. In view of the Congress of 1930, Mr. E. A. Bunyard (as Chairman of the R.H.S. Nomenclature Committee) was invited to open this discussion. His observations were of an explanatory nature and as each delegate was furnished with a copy of the R.H.S. report on nomenclature proposals in *The Gardeners' Chronicle* of June 29, his observations were followed easily and with great interest. At the conclusion of his remarks, the proposals (as set forth in our issue of June 29) were adopted, and Mr. Bunyard was heartily thanked for his presence and his elucidatory comments.

The final session, on Friday, July 5, opened rather late, as several Committees had met at 9 o'clock. A provisional promise of increased subscriptions was received from all the delegates.

The marking of imported Roses as now demanded by Great Britain caused a good deal of comment from Dutch and French growers, but M. Barbier's report, as was evident, had been made without full knowledge of the conditions laid down. Mr. Leak explained that nearly all goods imported into Great Britain had now to be labelled as foreign, with the country of origin in many cases, when exposed for sale. The marking of Roses did not affect exporters, it was the importer who had to mark the plants—under the Merchandise Marks Act—when he exposed them for sale.

International exhibitions were considered on a report presented by Mr. Krelage, and on the proposal of Mr. C. Engelmann, seconded by Mr. Jac Smit, it was agreed "that delegates present shall make strong representations to their respective Governments that in future flowers and plants solely for exhibition purposes should be admitted duty free."

The Conference accepted an invitation from the Italian delegates to meet next year in Venice, probably in September, as the German delegation proposed to invite the Conference to Berlin in 1931 instead of as previously arranged, in 1930. As a consequence, M. Mercatelli was chosen as President for 1930, and Mr. Schetelig Vice-President.

Very sincere were the thanks accorded to Mr. G. W. Leak for so ably presiding over the whole of the Conference proceedings; these thanks were voiced by Mr. Jac Smit, probably the most cosmopolitan of the delegates present.

Social events connected with the Conference included luncheon given to the delegates by the Royal Horticultural Society on Wednesday, when Mr. Gerald Loder presided; dinner, given to the delegates by His Majesty's Government, at Lancaster House, on Wednesday evening, when the Minister of Agriculture, Mr. Noel Buxton, presided; luncheon, on Thursday, given by the Horticultural Trades Association and the British Florists' Federation, when Mr. Rich presided, and the tables were charmingly decorated by Mr. Harry Miles, with Carnations given by Mr. C. Engelmann (President B.F.F.); a visit to Wisley on Thursday afternoon, when the R.H.S. entertained the delegates to tea; and visits to the exhibitions of the National Sweet Pea Society, the National Rose Society, the House of Commons, and the British Delphinium Society.

BRITISH DELPHINIUM.

The first show of this Society was held in the new hall of the Royal Horticultural Society, and augured well for the future exhibitions of this young Society, for it was a very successful event, the large hall being comfortably filled with exhibits. The trade was chiefly responsible for the success of the show, and we look forward, in future years, to amateur Delphinium growers—they must be legion—taking a more prominent part. We congratulate the British Delphinium Society upon its first attempt at staging an exhibition.

Competitive Exhibits.

These were divided into two sections, for amateurs and the trade, respectively, and while several of the amateur classes were well contested quite a number were sadly lacking in exhibitors.

Mr. W. C. Blakeway, Droitwich, was awarded the Blackmore and Langdon Challenge Cup, for the best group of Delphiniums staged on a table space eight feet by three feet, with an exhibit of magnificently grown inflorescences of many delicately coloured seedlings. For twelve spikes, in not less than six varieties, Mrs. Hamilton, Kingsmead, Claygate, was awarded the first prize, her spikes of Blue Bird, and also of several unnamed seedlings, being very good, while in the class for six spikes of six varieties, Mr. C. Reynolds, Walton Road, Bognor, was placed first, and Mr. L. D. Corder, Bromley, second.

Mrs. J. M. Docura, Surbiton, was awarded the premier award in the class for six spikes, not fewer than three varieties, with a very good set; the second prize going to Mrs. A. E. Gold, and the third to Mr. C. Reynolds; while in the class for six varieties, two spikes in each vase, Mr. L. D. Corder was awarded the first prize, his grand spikes being of Garbus, Modesty, Rapture, Peacock, Chamaeleon and Mrs. G. Day.

For three varieties, one spike of each, Mr. W. C. Blakeway was first, with three unnamed seedlings; second, Mr. L. D. Corder, who showed good spikes of Constance, Major Pat a'Beckett, and Amos Perry; third, Miss Phyllis Gold, Wilton Grove, Wimbledon.

Mr. Blakeway was first in the popular class for the best arranged vase of Delphiniums, with an attractive vase of grand spikes; the second prize-winner being Mrs. Hamilton, with Mr. E. A. Gold, third; while for the best arranged basket of Delphiniums—another popular class—Mr. L. D. Corder was placed first; Mrs. S. H. Roberts, second, and Mr. C. Reynolds, third. Mr. W. C. Blakeway showed the best spike of a light, semi-double, or double, Delphinium, exhibiting a grand spike of Quaker Girl, pale blue and pale mauve; second, Mrs. Hamilton, and third, Mr. F. Wynn Hillings, Kingston Hill, with a goodly spike of Mrs. A. J. Watson. Mr. Blakeway was also the winner of the Challenge Cup presented by Messrs. Hewitt and Co., for the best six spikes of new seedlings raised by the exhibitor, showing Perdita, light blue and pale mauve; George Bermay, with rich blue outer petals, the inner ones being mauve; Rosalind, and unnamed seedlings.

The most important competition in the trade section was for the Challenge Cup presented by Mrs. G. D. Gold, for the best group of Delphiniums on a floor space not exceeding thirty-six feet by eight feet, and the exhibits staged in this class constituted the chief feature of the show. Messrs. Blackmore and Langdon were easily first; in fact, none of the other exhibits approached the display set up by this notable firm, which was in the form of a huge rectangular pyramid, crowned with magnificent sheaves of Mrs. H. Kaye, Lord Lansdowne, deep blue, with a white eye, and Mrs. A. J. Watson, which towered above masses of grand, in fact, superb, spikes of Norah Ferguson, pale blue and soft mauve; Lorenzo de Medici, Constance, with large, single, Gentian-blue, white-eyed blooms borne in long spikes; Lady Gwendolen, semi-double and light blue in colour; Lavenda, Purple King, Mrs. Shirley, Lady Edith and Mrs. P. Nilke. At each corner of this magnificent group was an enormous basket of grand spikes of individual varieties, *i.e.*, Lady Edith, Mrs. Newton Lees, Blue Bird, very fine, and Lady Elizabeth.

Mr. W. Wells, junr., was awarded the second prize for a massive group of many sorts, but many of his spikes were somewhat lacking in quality. Among his outstanding varieties, however, were Mrs. Creighton, deep blue with a brown eye; Queen of Bath, soft blue, single; Corry, double, light blue shaded with mauve; Gwen, Mrs. Townley Parker, Lord Lansdowne, Glory, Joan Carter, Ludwig Wulmer, Duke of Connaught and Harry Smeatham, a grand sort with brilliant porcelain-blue flowers in an attractive, open spike.

In Messrs. Hewitt's group the most notable sorts were Will Shakespeare, Rose Marie, Duchess of York, Advancement, Norah Phillips, Blue Bird and Afghan Queen; Messrs. Chaplin Bros. had good spikes of Belladonna Orion, Rev. Charles Storr, Lady Faire, van Veen's Giant, Blue Star, Mrs. Creighton and Mrs. W. B. Mackintosh; while outstanding in the exhibit set up in Messrs. H. J. Jones' group were Glory, Ludwig Wulmer, Patricia, Enid a'Beckett, Mrs. H. J. Jones, Phyllis, Freedom and Major Pat a'Beckett.

Mr. T. Carlile was awarded the first prize for a group of Delphiniums on a floor space not exceeding fifteen feet by eight feet, and deservedly so, for his exhibit was charmingly arranged and contained many grand spikes, the best being of Mrs. H. Kaye, Beecroft, Mrs. R. Ashcroft, Lady Prince, Gloriosa, Mercurius and Queen Mary. Mr. T. Bones was second, showing Luxor, Clarissa, Mrs. Shirley, Hunsdon Dell, very fine; Mrs. H. Kaye, Rejnstroom and Rev. Charles Storr, in grand condition; Mr. Gavin Jones was third.

Messrs. Blackmore and Langdon were easily first for eighteen varieties, distinct, three spikes of each, and were the recipients of the Challenge Cup presented by Mr. G. F. Berney. Their spikes of Lady Eleanor, Doris, Lady Edith, Lady May and Mrs. Foster Cunliffe were simply magnificent, and they also included several fine unnamed seedlings. Mr. T. Carlile was second in this class, his best vases being of van Veen's Triumph, Mrs. T. Carlile, Mrs. H. Kaye, Millicent Blackmore and Norah Ferguson; third, Mr. T. Bones. Messrs. Blackmore and Langdon were also first for twenty-four spikes, distinct, showing a grand set, which included many lovely seedlings; second, Mr. T. Carlile, and third, Mr. T. Bones.

For twelve distinct varieties, three spikes of each, Mr. T. Bones was awarded the first prize, his spikes of Mrs. Hargreaves, Clarissa, Rev. Charles Storr and Mrs. H. Kaye being, perhaps, the best; while the premier award in the class for six varieties, distinct, three spikes of each, was won by Mr. T. Carlile, who had a grand set in Purple King, The Alake, Fair Lady, Lady Prince, Blue Boy and Lodden Guard.

NON-COMPETITIVE.

A quite attractive group of Delphiniums was set up by Messrs. KELWAY AND SON, good sorts included in their exhibit being Knight of Somerset, Quakeress, Geraldine Kelway, Dr. Lodwidge, Locarno, Cecil Henderson and Monarch of All.

In Messrs. BAKERS' group were good spikes of Edwin Beckett, King of the Delphiniums, Lady Faire, Othello, Mrs. H. Kaye, and others; while Mr. G. G. WHITELEGG included such charming sorts as Glory, Queen Wilhelmina, Harry Smeatham, Yvette Guilbert, Lord Lansdowne and Mrs. H. Kaye in his choice collection. Messrs. TUCKER staged a small group of the brilliantly coloured Blue Bird.

FIRST CLASS CERTIFICATES.

Delphinium Mrs. Hargreaves.—An enormous spike, about two and-a-half feet long, of large, semi-double flowers, the outer petals of which are electric Gentian-blue, and the inner ones pale mauve.

D. Hunsdon Dell.—A grand variety, with large, solid spikes of flowers, the wrinkled petals being rich blue, flecked with mauve. These two varieties were shown by Mr. T. BONES.

D. Lady Emsley Carr.—A tall, compact spike of light blue, semi-double, black-centred flowers. Very charming.

D. Lady Eleanor.—This lovely Delphinium has semi-double, very large flowers, which, when fully open, are soft blue, shaded with mauve; the petals are attractively waved.

D. Blue Gown.—A tall, open spike of large, reflexed, semi-double flowers, bright Gentian-blue, shaded with mauve.

D. Lady Bath.—An unique Delphinium, with very double and symmetrical flowers, the mauve petals being edged with electric blue. The flowers are carried on slender, wiry stems and the whole make up a very attractive inflorescence. This, and the above three Delphiniums, were shown by Messrs. BLACKMORE AND LANGDON.

AWARDS OF MERIT.

D. Mrs. Paul Nelke.—A close, rather slender spike of vivid, rich blue and white-edged, semi-double flowers. Shown by Messrs. BLACKMORE AND LANGDON.

D. Lady Elizabeth.—A large, compact spike of pale mauve and rich, bright blue flowers, flattened, and reflexed at the margins, with dark centres. Shown by Messrs. BLACKMORE AND LANGDON.

D. Pompadour.—A massive, very compact spike of medium-sized flowers, vivid, rich blue shaded with mauve. Shown by Messrs. HEWITT AND CO.

NATIONAL ROSE.

JULY 5 AND 6.—The Royal Hospital Grounds, Chelsea, divested of the kiosks along the Main Avenue, presented an unaccustomed appearance to the flower show visitor on the occasion of the Summer Show of the National Rose Society. In place of the multifarious exhibits of garden sundries which, at the R.H.S. Show, met the eye, was the placid restfulness of the arching green trees over the broad, gravelled drive—a fitting introduction to the glorious summer Roses which filled the tents. Although the large marquees were not entirely filled to capacity, there were many more blooms on view than the inclemencies of the season would have led the visitor to expect, and most of the countless Roses were of excellent quality. On the first day of the show, the elements were none too kind, even though rain which threatened, passed Chelsea by. But a veritable southerly gale sprang up, which, in this usually sheltered spot, tested the tents severely, and brought clouds of dust, some of which disfigured the lovely blooms. But, happily, this was not until comparatively late in the day, and after our Queen had delighted all rosarians by making a long and interested inspection of the many exhibits.

Although there was a slight uniformity in their arrangement, the large trade groups were very handsome, and contained masses of delightful and often delicious blooms. Fragrance was decidedly one of the features of a great show, and despite the dismal ones, many of the present-day Roses do emit a most appreciable and pleasant perfume. For some reason, which, at the moment, is not altogether clear, the amateurs' Roses certainly seemed to be more fragrant than those shown by trade growers. The competition in the amateurs' classes was so good that it must have pleased the Council of this flourishing Society. As ever, the new Roses were the centre of attraction to many visitors, who were content to await their turn in a considerable queue to inspect the nearly seventy novelties. Exercising a wise restraint, the Council awarded only three Gold Medals and four Certificates of Merit. The arrangements all worked with their accustomed smoothness, indicating thoughtful, efficient organisation and the many eager, waiting members and visitors were admitted well on the advertised time.

GOLD MEDALS.

Aureate.—A very beautiful H.T. variety which is recommended for all purposes and its appearance suggests full warranty for the claim. It is a fully double, rich yellow Rose, lightly warmed with pink in the heart, and well set on purplish stems. The foliage is good and the blooms have a pleasing fragrance. Shown by Messrs. ALEX. DICKSON AND SONS.

Elizabeth Arden.—This shapely, white H.T. Rose received a Certificate of Merit at the Saltaire Show, and now, deservedly, won the highest award. The white is relieved by light pink tinting on the buds and outer petals, and the young foliage is purplish. Many of the blooms had a distinct, long, leafy calyx, and they possess a slight, refreshing Tea fragrance. Shown by Mr. GEORGE PRINCE.

Gladys Benskin.—This Gold Medal Rose did not impress us quite so favourably as the others. It is a large, full H.T. bloom which loses form when mature. Under canvas the colour seemed to be a pinkish-mauve with a golden base to the petals. It is the most fragrant of the three varieties. Shown by Messrs. ALEX. DICKSON AND SONS.

CERTIFICATES OF MERIT.

Mrs. H. G. Johnston.—A very desirable exhibition H.T. Rose, fully double and of first rate form. It appears to be of sturdy robust habit. The broad, substantial petals are coloured rich pink, and the stems are tinted with purple. Shown by Messrs. BEES, LTD.

Peter Pan.—A good garden Rose of the same size and type as Emma Wright, from which it is stated to be a sport, and to be "very perpetual." The colour is a little variable, but generally seemed to be salmon-coral. Shown by Messrs. WHEATCROFT BROS.

Trigo.—A pleasing H.T. Rose which is recommended for all purposes. The shapely flowers are fully double and of rich deep yellow colour with a golden-salmon heart to the blooms. The buds and the outsides of the petals are tinted with purple. Shown by Messrs. ALEX. DICKSON AND SONS.

Crimson Glow.—This is a vigorous, climbing hybrid Wichuraiana Rose. The flattish flowers, which are borne in goodly clusters, are semi-double and of red colour, with a short, white line at the base of each petal. It should be a good garden variety. Shown by Messrs. CHAPLIN BROS.

OTHER NEW ROSES.

As we have stated, there were nearly seventy new seedling Roses submitted for award. Their quality generally was distinctly higher than the relatively few awards might indicate, and while the others did not gain any honours on the present occasion, the majority were well worthy of examination and, often, a certain amount of admiration. Some of the new Roses, notably George Howarth, Marion Horton, Rose Berkeley, Mrs. Sam McGredy, Mrs. S. Paton and Portadown, have already received the Certificate of Merit, and their appearance on the present occasion fully justified that honour, but did not suggest any promotion. Among the others, Mrs. J. D. Russell, a delicious, deep crimson H.T. variety, suggestive in type of the ever-popular General McArthur, should be a valuable garden Rose. It was shown by Messrs. BEES, LTD. Canary, shown by Messrs. ALEX. DICKSON AND SONS, will also surely be seen again. It is a medium-sized H.T. bloom of ideally good shape, clear golden yellow in colour, with rose-pink flushing on the outsides of the petals, and possesses a most refreshing perfume. The blooms were good in all stages and it appears to be valuable for the garden and as a cut flower. Felicia, shown by Mr. H. J. PEMBERTON, is a sweetly-scented garden Rose of pink colour. Attraction, shown by Messrs. ALEX. DICKSON AND SONS, is a rich, golden-yellow H.T. Rose, heavily flushed with rosy-cardinal on the outsides of the petals, and should be a good garden variety.

NURSERYMEN'S SECTION.

The tent devoted to the nurserymen's classes presented an even brighter spectacle than usual, for the Roses, in general, were of very high quality and of remarkably bright and clear colouring, so that the numerous groups entered for the first three classes, and which formed a giant double bank down the centre of the tent presented a brilliant and glowing spectacle.

There were eight entries in the premier class, for the Championship Trophy, which required a representative group of cut Roses on a space forty feet by four feet, and the judges must have had a difficult task in awarding the trophy, which was, however, secured by Messrs. ALEX. DICKSON AND SONS, LTD., who had a grand group of charming and original arrangement. Their lovely blooms were chiefly arranged in decorative baskets of varying size, set at different angles and levels so as to present an informal but very picturesque bank of blooms. In the centre, and half facing each other, were two huge baskets of Edith Nellie Perkins and Flamingo, respectively, other grand varieties arranged in similar receptacles being K. of K., Betty Uprichard, Adele Crofton, Scarlet Glory, Mabel Morse, Lady Inchiquin, Advocate, Shot Silk and Mrs. C. V. Haworth, the general effect being further enhanced by grand pillars of such sorts as Lucie Marie, Clarice Goodacre, Swansdown, Etoile de Hollande, Dame Edith Helen and many others.

Mr. ELISHA J. HICKS was a close second with a magnificent and charmingly arranged display, the blooms in this exhibit, of excellent quality, being arranged chiefly in pillars. There was a double row of these at the back; among the varieties so displayed being Pax, Padre, Christine, Ophelia, Scarlet Glory, Paul's Scarlet Climber and Lady Wakefield, while the front pillars were of shapely blooms of Shot Silk, Mrs. Henry Morse, Mabel Morse and Betty Uprichard. Among good sorts which formed the groundwork were Desmond Johnston, very fine; Hortulanus Budde, Lady Roundway, Angele Pernet, Lady Inchiquin and Ivy May.

The STANWAY ROSE GARDENS, LTD., secured the third prize with a charming arrangement, consisting of arches of such climbers as Emily Gray, Paul's Scarlet Climber, Allan Chandler, and Aviateur Bleriot, in front of which were huge ornamental baskets of Etoile de Hollande, Florence Izzard, Margaret McGredy, Golden Emblem and General McArthur, together with vases and bouquets of many other lovely sorts.

The fourth prize was shared by Messrs. WATERER, SONS AND CRISP, LTD., and Mr. J. H. PEMBERTON, both of which firms had very charming displays. The former had huge sheaves of brilliant blooms of Paul's Scarlet Climber, Independence Day, K. of K., Etoile de Hollande, Elsie Poulsen, Scarlet Glory and others as a background to huge circular bouquets of Mrs. Henry Bowles, Mrs. Herbert Stevens and Mrs. Henry Morse, and large ornamental baskets of Violet Stevenson and Mabel Morse, with a host of other grand varieties. The chief features in Mr. J. H. PEMBERTON's group were the tall sheaves of Seagull, Mary Wallace, Paul's Scarlet Climber, Havering Rambler and Papa Gouchalt at the back; lovely baskets of I. Zingari and Bernice, and grand vases of Anne, Golden Emblem, Lemon

Pillar, Los Angeles, Madame Butterfly, Dorina Neave, Lady Inchiquin and Ophelia.

Messrs. Benjamin R. Cant and Sons, Ltd., Messrs. Frank Cant and Co., and Messrs. Chaplin Bros. Ltd., also staged exhibits in this class. The first-named firm had handsome arches of Francois Juranville, Paul's Scarlet Climber and Emily Gray; large sheaves of Cupid, Climbing Madame Butterfly, Lemon Pillar and others, with baskets and vases of such grand varieties as Hortulanus Budde, Shot Silk, Mrs. Beatty, Independence Day, I. Zingari, Golden Gleam, Christine, etc. Messrs. Frank Cant and Co., Ltd. had a lovely basket of Golden Gleam, and pillars of Emily Gray, Pax, Mrs. Henry Morse, Etoile de Hollande, Hortulanus Budde and Shot Silk, together with many other sorts in vases, while Messrs. Chaplin Bros., Ltd., had very floriferous pillars of climbing sorts, notably Chaplin's Pink Climber, Royal Scarlet and Paul's Scarlet Climber, at the back, and in front of these were masses of Lady Forteviot, Mrs. Beatty, Ruth, Mrs. E. J. Hudson and Lemon Pillar, these being separated by pillars of grand blooms of Windsor, Emma Wright, Princess Elizabeth of Greece, Waltham Cross, Lady Helen Maglona and Lady Inchiquin.

In the competition for the De Escofet Memorial Cup, as in the previous class, the exhibits were of a very high standard. The trophy was awarded to Messrs. R. Harkness and Co., who had a lovely central arch of brilliant blooms of K. of K., surrounding a mass of Mabel Morse. There were lovely pillars of Lady Inchiquin, Lord Charlemont, Golden Emblem, Christine, Betty Uprichard and Mrs. Henry Morse, and large baskets of Rev. F. Page Roberts, Doris Trayler, Patience, and Lady Roundway, other grand sorts displayed being I. Zingari, Mrs. Beatty, Gwynneth Jones and Madame Butterfly.

The second prize in this class was won by Mr. George Prince, who had a central mass of the *Daily Mail* Scented Rose, with a grand basket of Mrs. Henry Morse above it. The background of the group was of pillars of Paul's Scarlet Climber, Mary Wallace, Allan Chandler and others; there were corner pillars of I. Zingari and Dainty Bess, and lovely baskets of Gwynneth Jones, Norma Lambert, Shot Silk, Mrs. Herbert Stevens and Lady Inchiquin, with many others. The Dowty's Rosery was third and Messrs. D. Prior and Son, fourth, the former firm showing lovely pillars of Hortulanus Budde and Shot Silk, and good vases of Ivy May, Captain R. Clark, Angele Pernet, Padre, I. Zingari, Etoile de Hollande and Golden Emblem.

In Class 3, for the Norman Rogers Challenge Cup, Mr. J. Mattock was placed first with a charming group in which the varieties Mrs. Oakley Fisher, Vesuvius, K. of K., Mabel Morse and Mrs. Henry Morse were of exceptional quality; second, Messrs. Jarman and Co., who had good blooms of Betty Uprichard, Angele Pernet, Shot Silk, Hortulanus Budde, Lord Charlemont and others; third, Mr. D. Long, who showed Hortulanus Budde, Lady Inchiquin, Golden Ophelia and Mrs. Henry Bowles in grand condition. Other exhibitors in this class were Messrs. A. J. and C. Allen, Messrs. E. Paul and Co., Messrs. A. Warner and Son, and Messrs. Morse Bros.

There were only two exhibitors in the class for seven baskets of cut Roses, seven distinct varieties, and these were Mr. J. Mattock and Mr. H. Drew, who were awarded the first and second prizes, respectively. The former exhibitor displayed a grand set, his best varieties being Betty Uprichard, Angele Pernet, Louise Prince, Golden Emblem and Shot Silk.

In the class for three baskets of cut Roses, three distinct varieties, thirty-six stems of each, there were five entries, three of which, however, were disqualified as being not according to schedule. Messrs. D. Prior and Son secured the premier award with lovely baskets of Lady Pirrie, Madame Edouard Herriot and Col. Oswald Fitzgerald; second, Messrs. D. Longley and Sons, who showed Colonel Oswald Fitzgerald, Golden Emblem and Norman Lambert.

Messrs. G. Longley and Sons were first for three baskets of Polyantha Roses, distinct, with Kirsten Poulsen, Else Poulsen and Diana, very fine; second Messrs. W. Cutbush and Son, Ltd., with Frank Leddy, Sunshine and Golden Salmon; and third, Messrs. D. Prior and Son, who showed Alice Amos, Else Poulsen, and Kirsten Poulsen.

There were six exhibits in the competition for the A. C. Turner Cup, for vases of thirty distinct varieties, the trophy being awarded to Mr. J. Mattock, whose best vases were of Mrs. G. A. van Rossem, Golden Emblem, Princess Elizabeth of Greece, Christine, Shot Silk, Angele Pernet, Betty Uprichard and Doris Trayler. Messrs. A. Warner and Son were second, and they had grand vases of Betty Uprichard, Captain Ronald Clark, Golden Gleam, Patience and I. Zingari; Mr. G. Lilley and Mr. F. Spooner shared the third prize.

As usual, the championship for exhibition blooms, for The China Trophy, was very popular, and some grand sets of blooms were displayed, Messrs. Frank Cant and Co., Ltd., securing the trophy. Perhaps their best blooms were of Lady Inchiquin, Golden Emblem, Nellie Parker, Gwynne Carr, Mabel Morse, J. C. Thornton, Augustus Hartmann, Captain F. Bald and Mrs. Henry Morse. In their second prize exhibit, Messrs. Benjamin R. Cant and Sons, Ltd., included grand specimens of Doris Trayler, Colonel Oswald Fitzgerald, Miss Willmott, Edith Cavell, Mabel Morse, Lady Inchiquin and William Kordes; while the best in the third prize set, by Mr. W. Slinger, were Florence Forrester, Lady Inchiquin, Portadown, Mrs. Bertram Walker, Mrs. Henry Bowles and The General. Messrs. G. Longley and Sons were awarded the fourth prize.

In the competition for the John Hart Memorial Cup, Messrs. R. Harkness and Co. were first with a set in which Mrs. Henry Morse, Mabel Morse, Lady Inchiquin, Red Star, Rose Marie, Lady Henry Maglona and Bessie Chaplin were outstanding; second, Messrs. Jarman and Co., who had grand specimen blooms of Mabel Morse, Mrs. Elisha Hicks, A. Cook, Mrs. Henry Morse and A. Hemsley; third, Mr. Elisha J. Hicks, who included The General, Lady Inchiquin, Mrs. Beatty, Louise Crinner and Colonel Oswald Fitzgerald.

Messrs. Jarman and Co. were awarded the D'Ombrain Cup, for twenty-four blooms, distinct, and they showed wonderful specimens of White Maman Cochet, Rev. C. Hall, W. R. Smith and Mrs. H. Hawksworth, Messrs. G. Longley and Sons being placed second, and Mr. H. Drew, third; while the Kilbee Stuart Memorial Cup, for twelve blooms of new Roses, distributed since January 1, 1925, was awarded to the Dowty's Rosery, who showed good blooms of Lady Florence Strong, Mrs. A. R. Barraclough, Dame Edith Helen, White Ensign, Mrs. Beatty and Ellen Terry. Messrs. D. Prior and Son were second, their set including Lady Helen Maglona, Dame Edith Helen, Arthur Cook and Desmond Johnson; third, Messrs. Benjamin R. Cant and Sons, Ltd.

Messrs. Benjamin R. Cant and Sons, Ltd., were first for twelve blooms of any new Rose distributed since January 1, 1925, with good blooms of Mrs. Beatty; second, Dowtry's Nursery, showing Dame Edith Helen, and third, Mr. G. Prince, who had good blooms of the *Daily Mail* Scented Rose. Mr. J. Mattock showed the best basket of cut blooms of a H.T. Rose, his variety being Bessie Chaplin; Messrs. G. Longley and Sons being placed second, with George Dickson, and Messrs. J. Jefferies and Son, Ltd., third; while Messrs. Jarman and Co., showing White Maman Cochet, were first for a basket of a Tea or Noisette Rose; second, Mr. H. Drew, with Mrs. Foley Hobbs; third, Mr. G. Prince; and Messrs. A. Warner and Son, Ltd., secured the Brayfort Challenge Cup, for one basket of cut Roses of an H.P., H.T., Tea, or Noisette variety, with moderate blooms of Margaret McGredy. There was only one exhibit in Class 16, for a basket of an exhibition or decorative Rose not yet in commerce, and this was by Mr. J. H. Pemberton, who showed Rebecca, of good form, with pale pink petals, rose coloured on the reverse side.

The Nickerson Prize, which is offered annually for the best new Rose of British or American origin sent out between June, 1922, and December, 1927, was again very popular. There were twenty-four stands of admirable Roses in competition for the valuable cup which was awarded to Messrs. Dobbie and Co. for their variety Duchess of Athol (p. 481, Vol. LXXXV), which recently received the R.H.S. Award of Merit. The other varieties of merit included Charles P. Kilham, N. A. Bilney, Bedford Crimson, Elizabeth of York, Patience, Golden Gleam, Lady Roundway, Mrs. Beatty, Shot Silk, Dame Edith Helen and J. C. Thornton.

AMATEURS' CLASSES.

In nearly all the classes of the Amateurs' Section the quality of the blooms reached a high standard of excellence, and the competition was very good. The Champion Trophy, for a representative group of cut Roses, was won by Mr. G. Marriott, Carlton, Notts., which was an admirable group set up in the best exhibition style. His chief varieties were Mrs. A. R. Barraclough, Souvenir de G. Pernet, Rev. Page Roberts, Emma Wright and Bessie Morse. Dr. C. R. Turnbull, Colchester, was second, and Mr. J. N. Hart, Potters Bar, was third, with the most representative exhibit in the class. Generally too many H.T. varieties were included. There were only two exhibits in the class for a smaller group, and here, again, H.T. varieties predominated. Mr. W. H. Pickford, Gloucester, was first, showing good vases of Ophelia, Golden Emblem and Etoile de Hollande; while Mr. H. R. Darlington, Potters Bar, was placed second, with a bright and graceful exhibit.

The Decorative Roses in baskets were of good quality and very attractive. The best two baskets were shown by Mr. G. Marriott, who had Betty Uprichard in excellent condition. With fragrant blooms of General McArthur, Mr. C. Dixon, High Wycombe, was first for one basket, and with very good specimens of Lemon Pillar, Mrs. L. Tilley, Northwood, was similarly successful in the class requiring twelve stems.

Mr. A. N. Rogers, East Putney, had the best basket grown within seven miles of London Bridge; and Mr. W. E. Moore, Ickenham, was the most successful of those who grow their blooms unaided. Mrs. P. Gordon Brown, Wrotham, won first prize in the novices' class

The Roses in vases were fresh and good. Mr. A. C. Turner, Woking, showing Sunstar, Betty Uprichard, Scarlet Glory and other good varieties, won the Mattock Cup; Mr. G Marriott was second with twelve good varieties. Mr. A. L. F. Cook, Hayes, Middlesex, had six exceedingly good varieties, and won the Holroyd Cup; while Mr. H. E. Cribb, Northwood, had the best six vases of climbing varieties. In the novices' class for climbing Roses, Mrs. M. Hancock, St. Albans, was first. Mr. E. H. Pleasance, Cambridge, set up an attractive set of six climbing varieties and won the first prize.

The exhibition Roses in boxes were highly creditable to the growers. Mr. F. H. Fieldgate, Colchester, won the Edward Mawley Cup with twenty-four admirable blooms, which included Mr. George Marriott, Mrs. Henry Bowles, The Queen Alexandra Rose, Mabel Turner and Hugh Dickson. Dr. Turnbull, in his second prize collection, had W. H. Walsh, J. G. Glasford, Bessie Chaplin and Mrs. Beatty, of very good quality. Mrs. W. J. Thorpe was third.

The best twelve specimens were staged by Mr. J. E. Rayer, Worcester, who included Mrs. R. C. McClure, Bessie Brown and Mrs. Henry Bowles; while Mr. F. H. Fieldgate was second. Mr. C. H. Rigg, St. Albans, showed the best two baskets of exhibition Roses. In Division B., Mr. H. F. Spicer, Hitchin, was the best of many exhibitors of twelve blooms in competition for the Lamplough Cup, and Mr. E. W. Turner was second. In Division C., the chief prize-winner was Mr. E. T. Gamm, Tankerton, whose twelve blooms were of considerable merit.

Although a few showed signs of the stress of the weather, most of the Tea and Noisette blooms were very shapely and beautiful. There were four exhibits of twelve varieties, and the trophy was won by Mr. W. E. Moore, whose best blooms were Mrs. Herbert Hawkesworth, Mrs. Campbell Hall, Mrs. Foley Hobbs and Auguste Comte. Mr. E. W. Turner was a good second, and he included Mrs. Foley Hobbs, Maman Cochet and Lady Plymouth, of fine quality. The best six blooms were staged by Mr. E. T. Gamm, who had Margaret Sharman

Crawford, Mrs. Edward Mawley and Myles Kennedy, in beautiful condition. Mr. L. Purden, Isle of Wight, had six exceedingly fine exhibition blooms in the class for amateurs who have never won a first prize with this type. His very best were of Mrs. E. J. Hudson, J. G. Glassford and Mrs. Foley Hobbs.

In the Metropolitan Class, Mr. W. Slocock, Carshalton, was the chief prize-winner, and Mr. A. N. Rogers, East Putney, was the most successful of growers residing within five miles of Charing Cross.

The Artistic Classes filled a large tent with very attractive arrangements. There was more variety than of late in the treatment of the Dinner Tables, and this added greatly to the attractions of the section. In the Nurserymen's Section, Mrs. M. Archer, who used Dainty Bess, was first in the Dinner Table class. Miss Tixdall won all the prizes in the bowl, vase and basket classes with artistic arrangements. In the amateurs' classes, Mrs. Courtney Page, Haywards Heath, added to her many successes by winning first prizes for a Dinner Table Decoration of Madame Butterfly in the open amateurs' class; for one of Emma Wright and Angele Pernet in the class for amateurs who grow their own Roses, and was second with Dainty Bess in the Table Class, where only single varieties may be used. In this class Miss Newsham, Liverpool, was first with the same variety. Miss Woolven had the best basket of Roses, and Mrs. Cooper was first with a vase of Roses.

ANSWERS TO CORRESPONDENTS.

Cucumber Stems Diseased.—*A. P.* The Cucumber stem was affected with canker, the causal organism of which is a bacterium, Bacillus carotovorus. Cucumbers at the period of ripening are physiologically weakened and susceptible to attack when the soil is very wet around the base of the stem. Avoid watering around the stem of the plants. Dust the bases of the stems at intervals throughout the season with a mixture of ten parts dry slaked lime, three parts freshly ground copper sulphate, and three parts flowers of sulphur.

Gloxinias and Tomatos unhealthy.—*T. J. C.* The Gloxinia and Tomato foliage is scorched and is due to the presence of sulphurous fumes in the atmosphere. There is no sign of damage by any pathogenic organism. The brown mottling on the lower surfaces of the Gloxinia leaves is due to the presence of many immature Thrips which may be seen along the mid-rib.

Herb in an old Garden.—*E. W. E.* The two leaves you sent were those of Fennel (Foeniculum vulgare). It is a herb, and has been used for a great variety of purposes from time immemorial. For home use it was formerly boiled with fish. The leaves at present are served with salmon to correct its oily character and make it more digestible. The leaves are also cut up and put into sauce, to be eaten with boiled mackerel. The seeds are used for flavouring, while an oil is distilled from them and used in the making of cordials. The leaves are also used for garnishing, and in Italy and France for flavouring salads; also in sauces served with puddings, when finely chopped. In Italy the young stems are employed in soups, and also eaten raw as a salad. Fennel is also used for scenting soaps by means of the distilled oil, and is employed in medicine as well.

Tomato Fruit Cracking.—*S.* The cracking of the Tomato fruit is probably due to faulty watering at the time of setting. The fruit bears no signs of fungal injury. It is impossible to suggest a reason for the curling of the foliage unless we are able to examine the entire plant.

Remarks.—All outdoor blooms have shown a slight increase in quantities, and prices are somewhat easier. Carnations are arriving in large quantities and prices range from 1s. to 4s. per dozen; the best sorts on offer are Delight, Favourite, Iver Pearl, Mavis, Lady Northcliffe, Mrs. Hemus, George Allwood, Lassie, Laddie, Eileen Lowe, Mrs. Ward, Wivelsfield Pink and Salmon Seedling (pink), Wivelsfield White, Enchantress and White Pearl (white); Aviator, Brilliant, Spectrum, Edward Allwood and Our Prince (scarlet); Enid, Mrs. Cobb and Topsy (crimson). Other choice sorts are Sunstar, Saffron, Circe, Royalty, Mikado and several fancy varieties in apricot and yellow, purple and mauve shades. Among Roses, the best grades have been somewhat shorter owing to the colder weather of the past week. White Pinks, Spanish Irises and Paeonies are practically finished for this season. The newest arrival in white blooms is Achillea The Pearl; white, mauve and pink Asters arrived in excellent condition this morning. More white, blue and pink Statice sinuata is now available and in much better condition. All Delphiniums are more than sufficient for present requirements. All Gladioli are similar to last week's quotations and continue to arrive in excellent condition; they now include some mauve and yellow varieties. All Liliums showed a tendency to be easier in price this morning as more white and pink L. speciosum were offered.

Remarks.—A considerable volume of produce is passing through Covent Garden Market just now, and the general condition of trade here may be considered good. The demand in the choice fruit section maintains firm values all round for the Peaches, Nectarines, Melons and Figs available. So far as Grapes are concerned, supplies are comparatively heavy, and although prices are slightly easier, the supplies move out well. Cherries have met a good demand, but their condition has been somewhat variable, and really good Cherries are not plentiful. Strawberries have had a good reception from buyers throughout the week and values have remained firm. Raspberries are selling freely at comparatively good prices. Gooseberries are on the scarce side, and green berries sell well, but those showing colour are not so popular. Arrivals of Tomatos are heavier, and while there is some slackening in prices, these are still at a level which is probably bringing some satisfaction to the producers. Cucumber quantities are still heavy, but are showing some falling off as compared with a short time ago, and quotations are lower. Mushrooms are not quite so plentiful and there are signs of an improvement in prices. Hothouse Beans continue to do well, but some marks show signs of the end of the season. There have been a few outdoor Beans on the market this week and these have sold well. Peas still find a weak market; what demand there is is mainly for finest quality, forced Peas being difficult to sell even at low figures. There is a shade of improvement in the trade for Potatos, but even so, the general price level is not good.

GLASGOW.

Cut flowers were very cheap last week, when price movements again favoured buyers. Irises in 6's were worth from 2d. to 5d.; Sweet Peas, 4d. to 6d. per bunch; specials, 8d. to 1s.; Carnations, 1s. to 2s. per dozen: pink Roses (Madame Butterfly and J. C. Mensing), 1s. 6d. to 2s. 6d.; red (Richmond), 6d. to 1s. 6d.; yellow (Roselandia), 1s. 6d. to 2s.; Lilium longiflorum, 2s. 6d. to 3s.; Gladioli, 6's, 1s. 3d. to 1s. 6d.; 12's, 1s. 6d. Calendula, 1d. to 2d. per bunch; Sweet Williams, 3d.; Gypsophila, 1d. to 3d.; Cornflowers, 1d. to 2d.; Smilax, 1s. to 1s. 6d.; Asparagus, short, 6d. to 9d.; flat, 9d. to 1s. 3d.; and trails, 1s. to 1s. 6d.

Strawberries dominated the fruit market, and the daily supplies found a ready market at firm prices, Scotch making from 10d. to 1s. 6d. per lb., and English, 10d. to 1s. Home Black Currants averaged 10d. per lb.; foreign, 6d.; Peaches, 9d. to 1s. 3d. each; Cherries, 8d. per lb.; Plums (Californian), 16s. to 18s. per tray; Apricots, 8s. per crate; Pineapples, 3s. 6d. each; Gooseberries, 4s. to 5s. per sieve; Pears, 9s. per tray; Grape Fruits, 40s. to 42s. per case (80's and 100's); New Zealand Apples, 22s. per case; Oranges (Californian Pure Gold), 25s. (216's).

In the vegetable section Tomatos sold at 8½d. per lb.; Cucumbers, 5s. to 6s. per dozen; Cauliflowers, 5s. 6d. to 6s.; Lettuces, 1s. 9d. to 2s. per box of 15 and 18; Peas, 3d. per lb.; Mushrooms, 2s.; Carrots and Turnips, 10d. to 1s.; and Asparagus, 2s. per bunch.

A TOO CROWDED ADVERTISEMENT WEARIES THE EYE; ONE WORD QUICKLY PERCEIVED IS BETTER THAN TWO NOT PERCEIVED AT ALL.

On the Growing of Onions.

MARKET gardeners do not produce sufficient Onions to supply the demands of this country, which, in consequence, finds itself importing annually well nigh ten million bushels, some half of which comes from Spain, a quarter from Holland, and much of the remainder from Egypt. Private gardeners are like unto their market brothers, not infrequently short in their supplies of this excellent vegetable, and therefore we need make no apology in drawing attention to the excellent leaflet No. 264, published by the Ministry of Agriculture and Fisheries, on Onion growing. The yield obtained varies remarkably in the different Onion-growing counties. Lincolnshire (Holland) comes first with seven-and-three-quarter tons to the acre; Kent, Essex and Middlesex have an average of six tons, and Bedford five tons per acre. In all, some 1,500 acres, yielding over 8,000 tons are under this crop, and a like or even larger area is employed for the raising of spring Onions which, of course, are pulled small and bunched green for salading. Although to raise a heavy crop requires no mean cultural skill, the cultivation to produce an ordinary crop is easy enough, provided that attention be paid both to the seed-bed and to weeds. The former must be firm, therefore ground for the crop should be ploughed in the autumn and left rough. Winter may help to consolidate it, and in any case the soil must be well firmed before the seeds are sown. Anyone who will observe the delicate gymnastics practised by the seedling in extricating itself from the seed-case will appreciate the reason why the small seeds needs must be sown in a firm and fine seed-bed. Next in importance among cultural operations is weeding. The Onion germinates quickly, and if it is to grow on unchecked, it must be saved from bootless competition both by early weeding and early singling. Less within the control of the cultivator, but of no less importance to the crop, is the kind of seeds which are sown; and in stating this we do not refer to the variety selected, but to the country from which the seeds are obtained. The vagaries of our climate make Onion growing for seed purposes precarious, and hence much of our seed is imported. In former years large quantities came from the south of France, but now, unfortunately, we have to look to California for supplies. We write unfortunately, because, according to Leaflet No. 264, Californian Onion seeds produce plants which mature a fortnight earlier than do those grown from English or European seeds, and, needless to state, the earlier maturity means a lighter crop. Onion growers often prefer transplanting to sowing, *in situ*, and this for several reasons. Transplanting admits of economy in seeds, helps to forfend attack by Onion fly and mildew, and conduces to higher yields. For transplanting, seeds are sown in frames or under glass, in gentle heat, the seedlings pricked out into boxes or frames, hardened off and transplanted in the open in April or early May. Giant Rocca and Large White Tripoli may, however, be sown in the open in autumn (September), left to stand over the winter and transplanted into firm ground in the spring. Needless to state, as with all transplantations, the less the injury done to the roots the more success attends the operation. As to manuring: Farmyard manure supplemented by artificial fertilisers is essential for high crop production; each acre should receive twelve tons of farmyard manure, four cwts. to six cwts. of superphosphate, two cwts. of sulphate of potash, and two cwts. to three cwts. of sulphate of ammonia; the last given in two dressings, the first of which should be applied immediately after thinning. Of varieties to sow there is a wide choice. The leading seed firms have taken endless trouble to produce varieties reasonably true to type, and in this somewhat difficult task they have been successful. So that, although not a few commercial stocks give bulbs of by no means uniform shape or colour, others of the selected strains are sufficiently true to name and type. One subject which might have received a line or two of comment is that of bolting, to which habit Onions are very prone. Gardeners who find Onions beginning to flower prematurely, as is often the case during a dry summer, may save the bulbs by bending down or removing the incipient flower heads.

Flowers in Regent's Park.—Very few of the many thousands of Londoners who visit Regent's Park at this time of the year to seek solace from their labours and shelter from the sun beneath the magnificent Horse Chestnut and other trees, realise fully the vast amount of thought and labour expended by those responsible for the maintenance of a continuously bright display of flowers. That this object is attained, and that thoroughly, may be ascertained by a visit to the park at the present time, while some idea of the high state of cultivation practised may be gleaned from the Supplement Plate, which we present with this issue, illustrating a grand bed of Hydrangea paniculata var. grandiflora in Regent's Park. At the present time the beds on the lawns flanking the grand avenue of Horse Chestnuts are gay with a great variety of flowers; to the left, the long, winding, herbaceous border is a mass of skilfully arranged colour, and to the right, bordering the large banks of shrubs, are bright beds of Delphiniums, Coreopsis, Antirrhinums and other subjects, while not the least among the numerous attractive features are the giant vases filled with pendant and very floriferous Pelargoniums. The beds on the lawns are in most instances, filled with separate subjects, brightest among which at the present time are the Nemesias, Hydrangeas in variety, Astilbe Garnet, Stocks, Clarkia Fire Fly, Viscarias of various colour shades, Lilium longiflorum and L. tigrinum var. splendens, and Godetias, while, later on, the large beds of Dahlias will prolong the floral display in this grand old park well into the autumn.

Captain F. Kingdon Ward.—We are glad and relieved to learn that Captain F. Kingdon Ward has made such a good recovery from his serious illness as to be able to continue his penetration into the fastnesses of North Tonkin in search of rare Orchids and other plants. Many of our readers will remember that, as we reported in *The Gardeners' Chronicle* of June 1, last, Captain Kingdon Ward was taken very seriously ill in a remote and hitherto unknown part of Tonkin, far from medical attention, and with only native bearers.

R.H.S. Awards of Merit to Wrongly-named Plants.—The plant which received an Award of Merit from the Royal Horticultural Society on June 11, under the name Cynoglossum cashmerianum (*Gard. Chron.*, June 15, p. 452), has now been identified as Cynoglossum nervosum, Benth. On June 25, a Rhododendron received an Award of Merit under the name Rhododendron Houlstonii (*Gard. Chron.*, June 29, p. 481). It has since been found that the plant exhibited was really a form of Rhododendron discolor and, as it is not an improvement upon the forms of Rhododendron discolor which have already received awards, the award made on June 25 has been cancelled.

The Hardy Fruit Crops of 1929.—In accordance with our usual custom, we have invited numerous gardener-friends to report upon the amount and condition of the hardy fruit crops in their districts, with the request that the reports be returned to us without delay. We shall be pleased to send forms to any fruit-growing readers who would like to send us reports of the conditions ruling in their areas.

N.R.S. Show of New Roses.—We learn that a large number of entries have been received from all parts of England, Scotland and Northern Ireland for the National Rose Society's exhibition of new Roses, to be held on July 23, in the Royal Horticultural Society's new hall, Greycoat Place, and there would appear to be every prospect of a good display of new varieties.

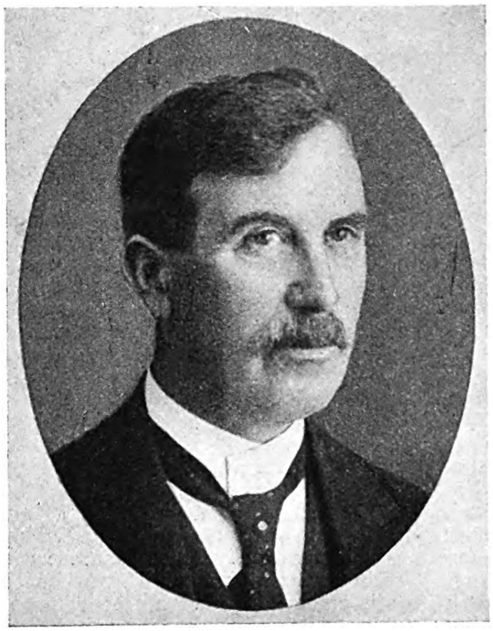
Legacy to a Gardener. — The late Miss Katharine Anne Jackson, of The Manor House, Dawlish, who died on April 22, 1929, left £100 to her gardener, Mr. John Short, if in her employ at the time of her death.

The Shortage of Water.—The Ministry of Health has issued to local authorities a "memorandum on water shortage," and in a covering letter addressed to the Mayors, the Minister states. he "considers it highly important that there should be no delay in taking measures for conserving existing water supplies wherever a shortage already exists or is threatened." The memorandum states that the recorded figures of rainfall for the early months of the year reveal a more pronounced scarcity than at any corresponding period since 1921. Although in a number of districts supplies appear not to be in danger, a continuance of the dry period through the summer months will involve more of the water authorities in shortage or risk of shortage. Also statistics indicate that rainfall for the next few years may continue to fall short of the average. A substantial improvement of supplies derived from surface sources is not to be expected in the near future unless exceptionally heavy rainfalls occur. Many deep-seated water supplies not yet affected may suffer later. Water authorities, therefore, should lose no time in scrutinising their position, with an eye not only to the present emergency, but to possible difficulty in the ensuing years. If existing supplies cannot readily be supplemented, measures should be taken early, even at some inconvenience to the consumer, to conserve them, thus avoiding more drastic restrictions later. The memorandum urges attention to leakages in mains and service pipes, and to defective taps and other household fittings, and recommends direct appeals to consumers to restrict their domestic uses to the more essential needs.

R.H.S. Gardens Club's Annual Outing.—On Saturday, July 13, just before 9 a.m., a party of thirty-one members of the R.H.S. Gardens Club left Wisley by motor-coach and proceeded direct to Ashford, Handcross, the residence of Mrs. Lindsay Smith. Here a tour of the beautiful gardens was made, and the visitors found much to admire, both in the herbaceous borders, which were exceptionally fine, and among the many grand specimen trees and shrubs—the giant Tulip Tree and Araucaria imbricata were specially noted. Before leaving Handcross, which the visitors were loath to do, they were kindly entertained to light refreshments by Mrs. Lindsay Smith, on the lovely terrace, from whence they were able to obtain a grand view of the South Downs. From Handcross the party proceeded to Worthing, where the Annual Meeting, at which Mr. E. A. Bowles was appointed President of the Club for the ensuing year, was held in Mr. J. E. Grant White's office. Lunch was taken at the Arcade Café, after which a number of the members went by motor-coach to Goring-on-Sea, where the gardens of Highdown, the residence of F. C. Stern, Esq., were inspected. The gardens proved a veritable treasure-trove of rare trees and shrubs, and the visitors were able to admire many of the original trees and shrubs raised from seeds collected during recent years in China, many of which have already become popular in gardens. Not only were the trees and shrubs a source of interest to the visitors, but the rock garden and the herbaceous borders, also the Lilies, which are grown well at Highdown, called for a great deal of attention, so that it was with a feeling that much real knowledge in the matter of plants and their cultivation had been gained that the visitors finally left Highdown, after being entertained to tea on the spacious lawn, to return to Worthing whence, after a brief halt in which to enjoy the lighter attractions of this seaside resort, the party returned to Wisley.

Essen and Ruhrland Horticultural Exhibition.—On June 29, in beautiful sunny weather, the long-prepared for and eagerly awaited Horticultural Exhibition was opened at Essen by the distinguished Minister Stegerwald, accompanied by a number of important personages. At the ceremony which preceded the actual opening, a hundred guests were gathered in one of the large halls of the exhibition, and many congratulatory speeches were made. Over 20,000 carrier pigeons were released at a given moment from the grounds, with a greeting to the world at large from the exhibition, and for a few moments after their release the sky was darkened with their fluttering wings. The exhibition is well prepared, and has the merit of being completely finished, a merit not always noticeable in large shows. Moreover, much of the work is of a permanent nature, for the site is to be retained as a public park, and may be used again as an exhibition ground if occasion offers. Although in the grounds there is much to interest visitors, it is a pity that at the opening the succession of indoor exhibition of flowers in season (such an attractive feature at Dresden) had not commenced, the first one, of warm-house and pot plants, being due to commence on July 6. The grounds are well laid out; there is a large lake, with fountains, which is well conceived, and a pleasant and restful terrace with pergolas; but these features badly want completing by well-developed green growth, which is difficult to supply, owing to the fact that the exceptionally cool, dry weather has retarded nearly all the planted growth and hindered the careful plans made beforehand. The Roses especially were very late, but doubtless the warm weather of the last fortnight has brought them on. It is to be hoped so, as Roses comprise the main feature of the second special exhibition, which also includes aquaria and terraria, the latter a feature which will interest English visitors, of which probably there will be a good many. This will last from July 20 to 28, and will be followed on August 3 by a special show of hardy plants, pot plants, Cacti, early fruits and vegetables.

Mr. G. W. Dunsmore.—Mr. Dunsmore, gardener to Albert Hill, Esq., Throstle Nest, Chillow Dene, Bradford, commenced his gardening career in the garden of Brooklands, Holywell Green, Stainland, near Halifax, the residence of Mrs. Shaws, and after spending some months there, where his work was confined chiefly to the glasshouses, he joined the staff of Messrs. L. Twigge and Son, nurserymen, florists and landscape gardeners, at Wakefield, but did not stay long with this firm, and soon returned to private service, obtaining the post of gardener to James Beverley, Esq., in the same town. Soon after securing this post, he joined the Wakefield Paxton Society, in the activities of which he soon became keenly interested, and did much yeoman service on its behalf. Mr. Dunsmore stayed with Mr. Beverley for seven years, after which he accepted the complete charge of Holmfield Gardens, Wakefield, then owned by the late Mr. Wigglesworth, but since acquired as a public park by the Wakefield Corporation. It was while in the employ of Mr. Wigglesworth that Mr. Dunsmore commenced his very successful career as an exhibitor of all classes of plants. Upon the death of his employer, Mr. Dunsmore moved from Wakefield to Bradford, where he obtained the post of gardener to Mr. James Hill, now Sir James Hill, at Throstle Nest, Bradford, the garden of which he has had charge of for the last twenty-two years. He served Sir James Hill for about seven years, and upon Sir James removing from Throstle Nest, Mr. Dunsmore stayed on as gardener to his son, Mr. Albert Hill, the present owner of the beautiful estate. During his charge of the garden, Mr. Dunsmore has carried out many alterations and improvements, so that it is now recognised as one of the show gardens of Bradford, while Mr. Dunsmore is regarded as one of the leading practical horticulturists in Yorkshire, his services as a lecturer being much in demand. Soon after his arrival at Bradford, he joined the Bradford Paxton Society; he was appointed a member of its Committee, eventually became its President, and is now a life member. Mr. Dunsmore took an active part in the work of the Bradford Chrysanthemum Society, while he has also been the Chairman of the Bradford Professional Gardeners' Society. For some years he held a post under the Bradford Education Committee as gardening instructor at the evening school. In 1911, the North of England Horticultural Society was formed, and Mr. Dunsmore was appointed Secretary of its Fruit and Vegetable Committee. He is well-known as an exhibitor, and is in great demand as a judge at shows in the north country; his greatest successes as an exhibitor have been with Chrysanthemums.



MR. G. W. DUNSMORE.

Retirement of Mr. Walter P. Wright.—After thirty-seven years' service, Mr. Walter P. Wright retires from the post of Horticultural Superintendent in Kent, in September, under superannuation. At a recent meeting, Sir Mark Collet, Bart., Chairman of the Kent Education Committee, paid a warm tribute to the value of Mr. Wright's work, which, he said, would never be forgotten in the county. Mr. R. Hart, of the East Anglian Institute of Agriculture, Chelmsford, has been appointed horticulturist, and will take up his duties at the newly-established Farm Institute, Borden, near Sittingbourne, on October 1.

Grants by the Empire Marketing Board.—Some idea of the valuable work that is being done by the Empire Marketing Board in the encouragement of agricultural research, may be gleaned from a report of the grants made by it to various agricultural and horticultural research stations in England and Wales, which appears in the July issue of the *Journal* of the Ministry of Agriculture, Vol. XXXVI, No. 4, p. 353. The grants are made for the purpose of permitting research in various specialised subjects, and are administered, at the request of the Empire Marketing Board, by the Ministry of Agriculture. The Long Ashton Fruit Research Station has received a capital grant of £7,025 to meet the cost of an extension of its existing laboratories, a cold store, an orchard house, glass shelter, and other minor items, with a maintenance grant of £2,425 for the first year, rising to £2,750 in the fifth year, for the purpose of investigating factors governing the keeping qualities of fruits in cold storage. East Malling Research Station receives a capital grant amounting to £9,050, and maintenance grants ranging from £5,218 in the first year to £5,685 in the fifth, for the purpose of conducting research on the relationship of stock to scion in connection with crop production and resistance to disease, while a grant of £800 for one year has been made to the Rothamsted Experimental Station to enable the construction and maintenance of six "Wisconsin" tanks to investigate the rôle of soil temperature and atmospheric humidity in the incidence of diseases attacking Cotton in the Sudan. Also, for the purpose of investigating virus diseases, the Rothamsted Station has been granted a capital sum amounting to £1,835, with maintenance grants totalling £2,495 in the first year, rising to £3,115 in the fifth, while the Cheshunt Experimental and Research Station receives a capital grant of £1,040, and a maintenance grant of £1,108 for the first year, rising to £1,260 in the fifth. A special grant of £1,600 for the erection of experimental glasshouses, and maintenance grants of £1,760 per annum for five years, have also been made to the latter Station to allow of the investigation of such glasshouse pests as Red Spider and White Fly, and various fungus diseases. A grant of £520 has been made to Reading University to enable experiments to be conducted in the treatment of seeds for the prevention of dry rot of Swedes and Turnips, which is very prevalent in New Zealand and is considered to be seed-borne. Other grants include £850 per annum for three years to the Department of Zoology, Oxford University, to enable research of the factors governing the fluctuation in periodic cycles; of the numbers of various rodents; a capital sum amounting to £4,350, for extension purposes, with a maintenance grant of £4,600, rising to

£4,950 in the fifth year, to the Welsh Plant Breeding Station; £400 to the John Innes Horticultural Institute, to enable an investigator from the Institute to undertake an expedition to the uplands of Uraq and Persia, to collect species and forms of Prunus and Tulipa; and £220 to the East Anglian Institute of Agriculture to permit of the experimental planting of Spartina Townsendii for preventing sea erosion. Annual grants amounting to £7,200 are made to the Royal Botanic Gardens, Kew, for various specified purposes.

The Linnean Society's Library.—The direct expenditure on the Linnean Society's Library from May 1, 1928, to April 30, 1929, was £1,482 1s. 10d., including the second moiety, amounting to £666 13s. 4d., of the grant from the Carnegie United Kingdom Trustees. The amount directly spent on the Library during the past two years exceeds the total amount spent during the first eighty-eight years of the Society's existence. During the year 520 works were purchased, and 236 books and reprints presented, making a total of 756 additions. The number of volumes bound was 1,595. The additions enumerated above do not include current periodicals, of which the Society obtains 396 by exchange, 167 by gift, and eighty-seven by purchase. Between May 1, 1928, and April 30, 1929, 1,250 volumes were borrowed by 162 Fellows and Associates, or roughly about one in four of Fellows and Associates resident in the British Isles. In addition, the Central Library for Students borrowed sixty-two volumes. The Society borrowed on behalf of Fellows and Associates four volumes from the Science Library, which are not included in the 1,250 volumes mentioned above. During the same period, 1,125 signatures—including 49 on Saturday afternoons—were recorded in the Library Visitors' book by 221 individual visitors. It is probable that the signatures in the visitors' book represent only a proportion of the Fellows and Associates who visit the Library. The general routine work of the Library was carried on as usual, and, in addition, valuable help was given by Mr. A. W. Sheppard, who catalogued all the additions to the Library and prepared the lists of additions which are now periodically printed in the reports of the General Meetings. He also collated several hundreds of volumes of periodicals, sets of which for various reasons were incomplete, and a considerable number of such sets were completed. The collection of General Hardwicke's drawings of Indian animals and the extensive sets of paintings of the collection of animals which Lady Impey, the wife of the Chief Justice of Bengal in the time of Warren Hastings, possessed at Calcutta, have been carefully cleaned by Mr. Sheppard and placed in Solander cases. Mr. James Robson, another volunteer, prepared an alphabetical list of the periodicals received in the Library, which it is hoped may be printed ere long, and also prepared an index of all the papers read at the general meetings for the last fourteen years.

The Scottish Sweet Pea Trials.—The first of the three official inspections of the Sweet Peas under trial by the Scottish National Sweet Pea, Rose and Carnation Society took place at Helensburgh, on July 6. One-hundred-and-two varieties are on trial. They were sown in the autumn, planted out in spring, and grown on the cordon system. Notwithstanding the break in the fine weather two days previously, the flowers were seen in good condition and in a more advanced state of bloom than was the case a year ago. There was also a general improvement in the purity of the stocks, single rogues being detected in only two varieties. The new white introduction, Vectis, which has hitherto produced a pink rogue in numbers, proved true, and among the novelties was a cerise-scarlet seedling with wings folding backwards, and a cerise-carmine variety which the raiser claims to be a new colour. According to the colour classification, pink and cerise shades were the most numerous, while the blue group was larger than it has ever been. The following were the most promising seedlings in this early stage of the trials:—Cerise-scarlet (No. 11) a weather-proof flower of rich colour; two stocks of a rose-cerise seedling identical in colour, one distinguished by the large size of the bloom, and the other by its double standards; No. 14, a distinct shade of pale creamy-pink, of decorative quality; No. 18, the best in the blue class, and a self-maroon (No. 96) of a pleasing shade. No. 23 was prominent by reason of the large size of the purple blooms and the predominance of four-flowered stems, and the pure salmon seedling reserved for the Gold Medal by the N.S.P.S. was seen to better advantage than in the bunch staged at the London Show. A second inspection will take place when the seedlings are in a more advanced stage of growth, and the final judging will be done on the day of the Society's show, when the flowers will be staged in vases.

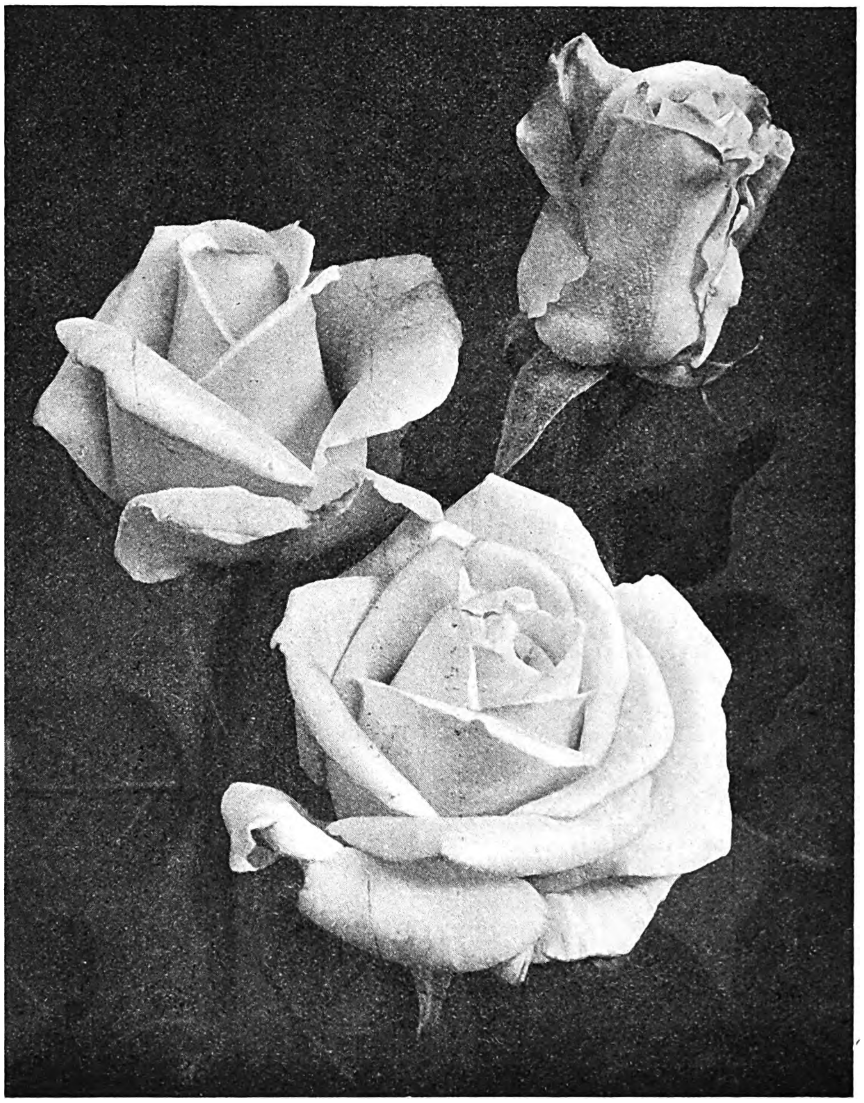


FIG. 23.—ROSE TRIGO.

N.R.S. Certificate of Merit, July 5. Flowers deep yellow and golden-salmon.
Shown by Messrs. Alex. Dickson and Sons. Ltd. (see p. 38.)

Appointments for the Ensuing Week.—MONDAY, JULY 22: Cannock Horticultural Society's Exhibition (two days). TUESDAY, JULY 23: National Rose Society's Exhibition of New Roses (R.H.S. new hall); Watford and Home Counties Horticultural Society's Exhibition (two days); Portsmouth and Southsea Horticultural Society's Show (three days). WEDNESDAY, JULY 24: Newcastle and District Horticultural Society's meeting; Dorset Horticultural Society's Exhibition (two days); Liskeard and District Horticultural Society's Exhibition; Romsey and District Gardeners' Association's visit to Harefield. THURSDAY, JULY 25: Saffron Walden Flower and Horse Show. SATURDAY, JULY 27: Leeds Paxton Society's lecture.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Sabbatia stellaris* (*Pursh.*).—A beautiful herbaceous plant, produced at the last Chiswick show by Mr. Ingram, from Frogmore. It is about a foot high, with opposite oblong leaves, and long-stalked, very sweet flowers, about a couple of inches in diameter. The corolla is deep rose colour, with a yellowish-green, star-shaped eye. Although well-known to botanists, neither this nor any other kind of Sabbatia has before occurred to us in cultivation; and Mr. Ingram may claim much credit for having shown how such plants are to be managed. It naturally occurs, according to Dr. Asa Gray, in *brackish* meadows, from Massachusetts to New Jersey and southward. It therefore demands a very warm season of growth, and Mr. Ingram grows it accordingly in a greenhouse. Gardeners are too apt to forget, when they hear of the great severity of winter in the United States, that the summers are, on the other hand, Neapolitan; and there can be little doubt that the reason why so many of the beautiful perennials of North America refuse to live with us, is that we turn them out-of-doors to experience the rigours of our wintry summers. *Gard. Chron., July 22, 1854.*

Publication Received.—*Fruit Culture*, by H. C. Davidson; Handbooks of Practical Gardening; pp. 142, illustrated; Messrs. John Lane, The Bodley Head, Ltd., Vigo Street, London; price 3s. 6d. net.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Manchester.

Control of Insect Pests: Red Spider.—Constant search and keen observation are always necessary to detect the various insect pests that infest many of the Orchids so that they can be removed before much damage has been done to the plants. This is especially so during spells of hot, dry weather sometimes experienced in the summer months, when red spider will often attack the undersides of the leaves of plants which are exposed to a fair amount of light and air, and although frequently syringed, the leaves and surroundings dry quickly, especially when hot and dry winds are prevalent. These pests often gain a hold on odd plants in any of the divisions, and if allowed to remain long, they will damage the tender foliage, which will soon assume a sickly, light-coloured appearance, and growth will be retarded thereby. It is, therefore, essential to the well-being of the plants to keep a keen look-out for the appearance of the pest and remove it by sponging the undersides of the leaves with soapy water or any mild insecticide. Spraying will often keep the pests in check, but once they have gained a hold, sponging is the best remedy in order to break the web under which the red spider works; applying specifics with a syringe strong enough to break the web would seriously damage the plants.

Thrips.—These are always troublesome, especially the small yellow thrips which increase rapidly under favourable conditions at any time of the year. These can be kept in check by regular spraying with an insecticide at fortnightly intervals during fine and dry weather, and fumigating the division on quiet evenings during the winter months or in unfavourable spraying weather. It is also advisable to have on hand a small vessel holding five ounces of water, into which is put six drops of pure nicotine (ninety-five per cent. to ninety-eight per cent. strength). With the aid of a good wing feather from a fowl, or a very small, soft brush, infested growths may be effectively treated with this. If the Orchid houses are near herbaceous borders or Corn fields, trouble is often experienced during the summer months by infestations of black thrips, which are sometimes blown through the ventilators and laps of the glass, while after rainstorms these pests may often be found alive in the water tanks, from which they are distributed around the plants, which they will infest in a short time. It is quite a usual thing in some districts under these conditions to find some live insects, particularly black thrips, the day after the division have been vapourised or sprayed. It is, therefore, essential to search regularly for any sign of the pests and deal with them as advised above. With Cypripediums and similar foliaged plants, the undersides of the leaves should be sprayed to remove the deposits left by the pests.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Strawberries.—It is the practice with some gardeners to plant the newly-rooted layers quite closely in the row—about one foot apart—with two feet between the rows, and so soon as the first crop of fruits has been cleared every alternate plant is cut out, leaving the remainder two feet apart each way. With some of the commercial growers there is a tendency to the other extreme, and they are adopting the "matted row" system; that is, they plant at eighteen inch intervals in the row, and allow thirty-six inches between the rows for the convenience of horse or mechanical cultivation. The first July after planting, however, the runners from these plants are thinned down to about four per plant. These are layered between the parent plants to form a matted row of strong, virile plants capable of producing a very large quantity of fruits for the next three years. They are then scrapped.

Maincrop Strawberries.—The main planting should be carried out at the earliest possible opportunity, so that the plants may become established before the end of the growing season. It has been proved at Botley and elsewhere that early planting, even to the extent of the last week in June or the first week in July, gives a very appreciable increase in crop and general vigour, and that these advantages are carried on in each succeeding year in similar proportion. Strawberries planted in August, September and October showed a progressive decline in crop records taken over a period of three years. The cultivation of the Strawberry is a problem at the moment, but no doubt it will soon be overcome. Growers should endeavour to prepare the soil well, to plant early, and to keep the soil between the rows well stirred so as to encourage root development from the very start. For this main planting, a distance of from fifteen inches to eighteen inches should be allowed between the plants and thirty inches between the rows. Plant firmly and rather deeply, and keep the plants well watered until they are established. Immediately the planting is completed, the cropping plots should be cleared of all runners, weeds, and the longest straw, the soil between the rows should be lightly cultivated to form a mulch, and a little of this drawn up about the bases of the plants to protect the new roots that are now being formed.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Early Peach House.—When all the Peaches have been gathered, shoots which have fruited and are no longer required should be cut out to make room for the new growths and to let in light and air, without which ripe wood and plump buds can hardly be expected. Next to thinning the growths, the most important necessities are cleanliness and freedom from all insect pests. The roots, needless to state, should be kept thoroughly moist, applying clear water or diluted liquid manure, according to the condition of the trees, care being taken that the latter, or mulches, are not applied too heavily, as an excess of either will result in gross growth when the wood should be ripening. Old trees which have been cropped heavily often lose whole branches when thinned and exposed to full sunshine; free ventilation and liberal waterings at the roots are excellent preventives, but these should be supplemented by training the young shoots over exposed branches, or by shading lightly.

Successional Peach Houses.—Fruits in these houses have made rapid progress, and any time lost at the beginning has now been redeemed. As this gain must be maintained, liberal thinning should be completed and the growths finally tied in. Thorough syringing should be practised twice a day, using soft water, or water free from lime, the last syringing being done about 4 p.m., when the house should be closed for three or four hours to assist the swelling of the fruits. Liberal supplies of clear water or stimulants, according to the strength of the trees and the weight of the crop, should be given. Peaches approaching ripeness should be protected from rain splashing through the ventilators, and not syringed, or they will soon be spoiled; a certain amount of moisture is essential but this can always be provided by damping the stems and floors after the ripe fruits have been gathered.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Hardy Perennials.—A considerable number of hardy perennials may be increased readily by cuttings at this season, and an endeavour should be made to insert a few of all scarce and rare plants which may be increased by this means, in case stock plants are lost during the winter. Cuttings of the current year's growths which are becoming moderately firm, inserted in pots of sandy soil and placed in a cold frame, which should be kept close and shady for a time, usually give satisfaction.

Seed Sowing.—Seeds of new and choice plants as they become ripe, ought to be given special attention. Many rare plants have been lost to cultivation through the thoughtlessness of the private grower in not taking the precaution to save his own seeds, thinking he could procure them from a seed-firm when required in future. As many of these are in only a few people's hands to begin with, it is essential that all should help to save and distribute seeds of rare plants when opportunities occur. Specially good forms of any plant should always be marked for seed saving. It adds considerably to the pleasure of gardening to be able to grow strains of one's own selection.

Border Carnations.—These were extremely popular plants in many gardens a number of years ago, but have been partly neglected since the cultivation of the perpetual-flowering varieties has been taken up so extensively. None the less, they are a group that a great deal of real pleasure can be had from. They make ideal clumps for the mixed border, where, apart from their flowers, the blue-grey of the foliage is always attractive. Probably the method whereby they may be seen and examined to greatest advantage is to plant them in a narrow border in three lines; under such conditions it is an easy matter to reach any individual plant. Layering is the method usually practised to increase the stock, and no time should be lost in getting this work completed, so that the plants have ample time to become sufficiently rooted before the middle of September, when they may be planted in their permanent quarters. If the soil is heavy, light loam with plenty of sharp grit added should be worked around the plants before layering. See that the "tongue" is sufficiently long and the cut kept open, and the whole made firm, using pegs for this purpose. Wire pegs can be bought or made; where Bracken is at hand, a plentiful supply of pegs is available by using the stems of this.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Humea elegans.—Plants of this subject are now developing their plume-like inflorescences, and should be given frequent doses of weak liquid manure. A cool, airy house and plenty of room should be afforded them if they are to give the best results. Seedlings of this subject are now ready for pricking off into small thumb pots, this being preferable to pricking them off into boxes; a light, sandy compost is best for them at this stage, the rooting medium being made stronger as growth proceeds. This plant should not be subjected to high temperatures caused by artificial heating, but should be grown under the coolest conditions possible throughout all stages of growth.

Chrysanthemums.—Plants that are being grown to produce large exhibition flowers will by this date have filled their receptacles with roots, and it will be found necessary to supply the latter with some weak stimulants to keep the plants healthy and vigorous. With the dry season we have experienced the plants have had to be watered frequently, which must have greatly reduced the plant food contained in the soil. Although I recommend feeding the roots, I do not advise the use of strong nitrogenous manures at this stage of growth. Several good proprietary manures are to be obtained, and if these are used strictly to the makers' directions, they should give the desired results. Weak soot-water is a safe stimulant and should be applied alternatively with liquid manure; the latter can be made by placing sheep, horse or cow manure in a bag, and soaking it in water for a few days before using the clear liquid which, if strong, should be diluted with clear water. Chrysanthemums delight in a change of food, and if feeding is done judiciously, good results should be forthcoming. Pay strict attention to disbudding and the removal of all side growths. It is also essential to keep all growths tied neatly to their supports or they may be broken off by strong winds. Examine the plants frequently for mildew and insect pests. Single and early bush Chrysanthemums will also require some assistance in the way of feeding, preferably with soot-water and weak liquid manure, until such time as the buds are taken, when a concentrated manure may be necessary to assist them to produce good flowers.

Eranthemum pulchellum.—Plants of this delightful winter or early spring-flowering stove plant should be potted on into larger receptacles so soon as the cutting pots become filled with roots. The potting compost may consist of good fibrous loam with some peat and a liberal supply of sharp sand added. During the early stages of growth, the shoots should be pinched out several times to promote a bushy habit, and the plants shaded from bright sunshine. The best results are obtained by growing them near the roof-glass in an intermediate house during the summer months. Syringe the foliage throughout the growing season to keep red spider and thrips in check, which are very partial to this plant. When the receptacles in which the plants are to flower are well filled with roots, frequent applications of weak liquid manure will prove very beneficial to them, for they are gross feeders; under suitable conditions E. pulchellum will flower for several weeks.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Asparagus.—The cutting of Asparagus should now cease, to enable the plants to build up strong crowns for next year's crop production. The growths will need support against winds and heavy rains as they are easily broken off at the base. The bed may receive a dressing of a quick-acting fertiliser during the summer, and should be kept free from weeds by hand-weeding. Beds of seedlings should have every attention; give a dressing of salt and apply a mulching of short litter between the rows to prevent the soil becoming dry.

Peas.—To secure late crops of Peas, seeds may be sown now. Make a trench and place plenty of decayed manure in the bottom of it, and on this place a layer of soil. Choose an open site for this sowing, as in such positions the plants are less susceptible to attacks of mildew than if planted in shaded or crowded quarters. Sow early varieties, as these mature their crops more quickly than main-crop sorts.

Seakale.—Examine the Seakale plants, and where there are several crowns, rub off all but one to each, so as to secure good strong crowns. Seedling plants from seeds sown in the spring, if too close together, should be thinned out to a reasonable distance apart. Keep the plants free from weeds by using the Dutch hoe between the lines frequently.

Seed sowing.—Further sowings of Lettuce, Radish and Endive may be made to provide crops for autumn use. Plants of Lettuce and Endive in seed-beds may be planted out during showery weather to maintain a regular supply.

Kales.—Scotch Kale and Sprouting Kale may still be planted on ground from which early Potatos, Turnips and other crops have been lifted. Allow plenty of room between the plants.

Runner Beans.—These are now growing freely and should be examined from time to time to see that the leaders are going the correct way; if not, train them in the right direction. At present the weather, being showery, suits Runner Beans, but should it be dry, never let the roots lack moisture. As the Beans begin to form, apply a little artificial fertiliser or liquid manure.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemont, Monkton, Ayrshire.

Carrots.—A sowing of stump-rooted Carrots should be made to afford a supply of fresh roots; these are preferred in most cases to the long-rooted kinds, but they soon get out of condition, even if they escape the dreaded Carrot fly.

Cabbages.—If Cabbage plants are required for autumn planting, seeds should be sown now to ensure good plants before growth ceases. Ground cleared of early Potatos is most suitable for this purpose and need only be levelled and trodden preparatory to drawing out the drills, which, as in the case for most small seeds, should be shallow and one foot apart. Sow the seeds thinly or transplant the seedlings into nursery rows when the first rough leaves show. Where finches and sparrows abound, a net should be placed over the seed-bed.

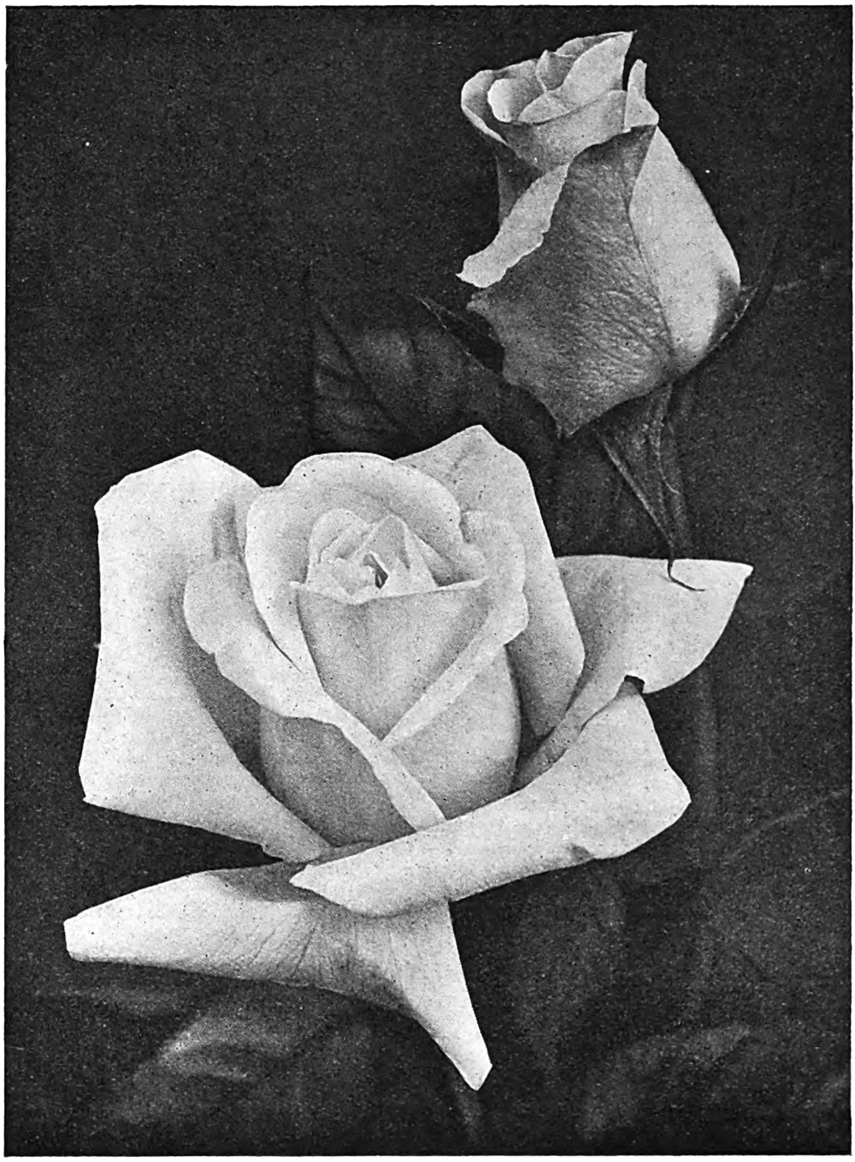

FIG. 24.—ROSE AUREATE.

N.R.S. Gold Medal, July 5. Flowers rich yellow, tinted with pink. Shown by Messrs. Alex. Dickson and Sons, Ltd. (see p. 38.)

Lettuces.—A good breadth of Lettuce should be sown, and when the seedlings are large enough, they should be thinned out to one foot apart. Plants from this sowing may be kept in good condition well into the autumn if protected from cold rains. The Chase Continuous Cloche is ideal for this purpose, as no attention is required after placing these in position.

Dahlias.—Thin out the growths of these until only four or five are left to each plant and encourage these by applying water at the roots and spraying the foliage in the evening. As lateral growths develop, retain only so many as will have ample room for development. Stake the growths retained as they lengthen, and give an occasional dose of liquid manure.

Old Cyclamens.—These should now be quite rested and clear of foliage. Soak them in a tank of water until the soil is thoroughly wet, after which they may be placed in a cold frame until root action commences, when they should be repotted. Those in small pots should be potted on without root disturbance, but where the maximum size of pot has been reached, it is necessary to slightly reduce the old ball of soil and return the plants to pots of the same size. Ample drainage should be afforded and the compost should be free and open. I find Cyclamens do well in a compost of equal parts fibrous loam and rough leaf-mould, with a small quantity of lime-rubble, charcoal and rough sand added. Should the loam be light in texture, an additional quantity may be used. No animal manure should be given, but a dusting of bone-meal and Clay's fertiliser will be beneficial. After potting, the plants should be placed in a frame with a northern exposure, and sprayed regularly and frequently during hot weather. Shade them during the heat of the day, and close the frame for an hour or two as the sun declines; on warm nights remove the lights completely. Water should be given carefully until root action is free, after which the compost should never be allowed to approach dryness.

PLANTS NEW OR NOTEWORTHY.

PAULOWNIA FARGESII, FRANCHET.

It is interesting to record the flowering of this Paulownia for the first time at Kew early in the month of June this year. The tree was received as a small plant from M. Maurice de Vilmorin in the autumn of 1908. It is now, after twenty-one years' growth, about forty-five feet in height.

The species was first described by Franchet in the *Bulletin* of the Paris Museum of Natural History in 1896, from specimens collected by the Abbé Farges in the mountains of north-eastern Szechuan. Mr. Augustine Henry collected specimens in the mountains of Hupeh, and Mr. E. H. Wilson found it during 1904, and again in 1908. Mr. Wilson describes it as a common tree, forty feet to sixty-five feet in height, in western Szechuan, growing at 900 feet to 4,000 feet elevation.

The first record of the tree flowering in Europe was in the nursery of M. Boucher, in Paris, during the early summer of 1905, on plants raised from seeds sent by the Abbé Farges to M. Maurice de Vilmorin, presumably about 1896.

The Kew tree is growing in a very sheltered position in the Rhododendron Dell, protected by tall woodland trees on the north, east and south, the sun reaching it only during the late afternoon on the west. As one would expect in such a position, the tree is rather "drawn up" and loose in habit, but this weakness may be readily overlooked when the object aimed at—to flower the tree—is attained.

Most of the stronger shoots developed a terminal panicle of flower buds in the late autumn of 1928, and although the winter was more than usually severe, most of the embryo flower-buds escaped unharmed. The first flowers opened towards the end of May and continued into June. The illustration of an inflorescence (Fig. 26, p. 51) gives some idea of the build of the panicle of blossoms. The flowers are pleasingly fragrant, lavender or pale violet in colour, with two yellow bands in the throat, and dark spots.

The best-known species of Paulownia is P. imperialis, Siebold (*syn.* P. tomentosa, Koch.), but it is only in the milder parts of the country that the embryo inflorescences, which form in autumn, survive the winter. The figure in the *Botanical Magazine*, t. 4,666, was drawn from an inflorescence cut from a tree which flowered in the Bishop of Exeter's garden at Bishopstowe, near Torquay, in 1852. There is a well-known tree in the Cambridge Botanic Garden which produces the Foxglove-like blooms fairly regularly. The blue-purple flowers with yellow stripes and dark spots are pleasingly fragrant.

Even if it is not possible to secure flowering trees in many British gardens, Paulownia imperialis is worth cultivating for its attractive foliage. Planted in rich soil and kept to a single stem, growth made in one season often reaches ten feet to twelve feet high, with leaves two feet to two-and-a-half feet in diameter. The growths should be cut down to within about one foot of the ground each year, early in March. Propagated by root cuttings or raised from seeds and grown in this way, P. imperialis is an attractive subject for the sub-tropical garden, or as a group of a dozen or more plants in a lawn bed.

Having read of, and talked with persons who have seen, the trees of Paulownia imperialis forty feet to fifty feet high, flowering in the Jardin des Plantes, in Paris, one is forced to the conclusion that it is not the frosts alone which destroy the buds in winter; rather is it the alternating spells of mild weather and frosts which we experience in British gardens. A moist, warm period during January or February awakens growth in the dormant flower buds; this suddenly changes in a night or two to sharp frosts, and irreparable damage is done.

This, and the flowering of P. Fargesii at Kew, suggest that the only hope of flowering Paulownias with any degree of success in the average climate of British gardens is to select very sheltered positions for them.

A number of other species of Paulownia have been described and named. Several have been raised from seeds collected in China, but it is, unfortunately, only in the favoured gardens of the south and west that their successful cultivation is likely.

P. Duclouxii, Dode (Wilson, No. 3,170).—This species was found at 900 to 3,000 feet elevation by Mr. E. H. Wilson in western Hupeh, during April, 1907.

P. Fortunei, Hemsley.—A native of north and south China, described by Dr. Hemsley in the *Journal* of the Linnean Society in 1890.

P. glabrata, Rehder.—Described from specimens collected by the late Mr. W. Purdom at Shensi, in 1910.

P. tomentosa var. lanata, Schneider.—Collected by Mr. E. H. Wilson in W. Hupeh during 1907, at an altitude of 4,000 to 6,000 feet. A tree of this species (Wilson 769) thirty feet in height, growing at Aldenham, is figured in *The Gardeners' Chronicle*, Vol. LXXII, Fig. 68, p. 167, 1922.

P. meridionalis, Dode.—Described in 1908 in the *Bulletin* of the Dendrological Society of France.

P. recurva, Rehder.—This is Wilson's 769A, and is near P. imperialis, but much less tomentose. Mr. E. H. Wilson found it at about 4,000 feet altitude in western Hupeh in 1907.

P. thyrsoidea, Rehder.—This species is stated to differ from all other Paulownias in the coarse dentation of the leaves. The inflorescences are larger than those of P. Fargesii, the species illustrated, but the lavender flowers are rather smaller. Specimens were collected by Mr. S. T. Dunn during 1905 in western Hupeh, and by Mr. E. H. Wilson two years later. *A. Osborn.*

INDOOR PLANTS.

HYDROCLEYS COMMERSONII.

This aquatic is known under two other names, *i.e.*, Limnocharis Humboldtii and Vespuccia Humboldtii. Hydrocleys Commersonii is the correct name for the plant. It is a very fine member of the Natural Order Alismaceae, and is a native of Brazil.

The flowers are borne on fairly long stalks rising above the surface of the water. The petals are three in number and are a beautiful clear and glistening yellow in colour, shading to gold in the centre. The stamens are dark brown and stand out well in contrast to the other parts. The leaves are ovate and somewhat inflated on the underside in the centre; many of them float, but the majority stand up just above the water.

H. Commersonii may be cultivated in tubs or cisterns, or in the shallower parts of an aquarium. The plants should have their roots in good, rough loam, and be submerged to a depth of about four inches. Propagation is usually carried out by means of division of the older plants, but it may also be effected by rooting the runners, and by seeds. *F. H. Wright, Cambridge Botanic Garden.*

ORCHID NOTES AND GLEANINGS.

PHALAENOPSIS.

Most Phalaenopsis species and hybrids, of graceful habit and free-flowering, thrive well in a moist position near the roof-glass in the warm house, although it is often found that one particular position suits their requirements, and they fail to grow well in any other, even in the same house. It is, therefore, advisable to note the position where the plants succeed best, the health and vigour of the specimens being the surest guide to this. Phalaenopsis are shade-loving subjects, and should be protected from direct sunshine, which soon damages the tender foliage, but the plants require plenty of light to assist their development during the summer, which is the growing season for most kinds. Plenty of moisture, both in the atmosphere and at the roots is required, and the atmosphere should be kept sweet by judicious ventilation.

The majority of the plants will now be producing new roots, and fresh rooting material should be afforded. Where the plants are not leggy and are accommodated in pans or baskets of a suitable size, the old compost and decayed roots should be removed carefully and the drainage made perfect. Fresh material, consisting chiefly of chopped Sphagnum-moss, with a little A.1. fibre intermixed, should be inserted, adding lumps of charcoal as the work proceeds. Where it is necessary to remove the plants to other receptacles, the live roots which are clinging tightly to the pans should be carefully removed with the assistance of a thin knife blade or a similar instrument, avoiding injuring them so much as possible. After disturbance, water should be given sparingly until growth and roots are more advanced, when increased supplies will be needed. During the winter, when the plants are not active, very little water is required at the roots, and a less humid atmosphere is necessary to prevent decay and spotting of the foliage. *D. G.*

TREES AND SHRUBS.

RHUS TOXICODENDRON.

Poison Ivy is the name by which this North American shrub is commonly known, and only too well does it deserve this designation, for it possesses the property of causing a severe attack of eczema-like eruptions to break out on the skin of many people. It is the milk-like sap which possesses toxic properties, and should this come in contact with the skin, blisters and eruptions quickly make their appearance. These are exceedingly irritating and painful, and the desire to alleviate the irritation by scratching, if given way to, only results in spreading the infection. Certain people are immune to this poison—I believed myself to belong to this class, and have handled Poison Ivy with impunity on many occasions, but recently, after pulling some plants up, a severe attack of the blisters appeared on my face, although my hands and arms were free from infection. Others are so susceptible that contact with the plant is not necessary, mere proximity to living bushes inducing an attack. It would appear that in such cases the pollen, dispersed by the wind, is the cause of the trouble, for the evil effects are particularly noticeable on the eyes. Many cures are advocated, the most reliable of which appears to be lead acetate.

Poison Ivy is very abundant in the eastern United States, and occurs in two distinct forms, the one climbing over rocks, bushes, trees, etc., and attaching itself by means of aerial roots, and the other of bush form, attaining a height of eight or nine feet. The compound leaves are very attractive and are invariably composed of three leaflets, the two side leaflets having much shorter stalks than the terminal one. They vary somewhat in shape from broadly ovate to obovate, and have either entire or coarsely notched margins. The upper surface is of a rich green hue and is somewhat glossy in appearance, while the under surface is more or less pubescent. In the fall, the foliage assumes gorgeous orange and scarlet shades, and oft-times deceives the unwary into gathering armfuls for decorative purposes. The flowers are insignificant, being dull white or greenish, and are borne in slender, axillary panicles during spring and early summer.

Rhus Toxicodendron is a beautiful climber, but, unfortunately, it is not safe for general cultivation, and should only be tolerated in places where its dangers are clearly known and understood. *T. H. Everett, New York, U.S.A.*

STYRAX WILSONII.

This beautiful shrub has been the most satisfactory of its genus tried here. It is a deciduous species, discovered by Mr. E. H. Wilson in north-west China about twenty years ago, when he was plant collecting for the Harvard University. Growing to eight or ten feet high, S. Wilsonii is a slender, upright shrub with an open, twiggy habit.

The ovate leaves are about an inch long, pale green and slightly downy in the spring. Soon after mid-summer the flowers appear on the short, lateral twigs, the star-shaped corollas, which are over half-an-inch across, being a pure glossy white and the anthers yellow. The flowering season lasts for fully six weeks. I have found S. Wilsonii to flower regularly and freely, and my specimen, now nearly fully grown, is a most charming object when every one of its fine little shoots is enlivened with the whiteness of the sharp-pointed blossoms. Happily, this very beautiful shrub came through the trial of last winter with no more than minor injuries to the tips of the branches. It had no protection whatsoever, and was standing well away from, and rising above, a low westerly wall.

This species seems to do well in an average light loam, which is lime-free, and it asks no special cultural attention. Seeds have not been ripened here, and cuttings seem difficult to manage, at any rate from an amateur's point of view. But S. Wilsonii, however it may be raised, will respond by beginning to flower at a very early age, which is an attribute of no small merit in itself.

NOTOSPARTIUM CARMICHAELIAE.

ALTHOUGH I had occasionally seen this fine plant well grown and flowering freely in other gardens, notably Bodnant, it was not until early July of the present year that an old specimen of my own decided to save a vanishing reputation by flowering. It has since been a mass of colour and the pinky-lilac blossoms are borne most elegantly on the slender, arching twigs.

The Pink Broom of New Zealand comes from the South Island, but it is stated to be rare as a native. Mr. Bean does not consider it hardy at Kew, but in my very dry, thin soil it came through last winter without the slightest injury, Ceanothuses, Fremontias and Dendromecons all being killed within a few yards of it. It is entirely leafless, save when young, the green, Rush-like branches suggesting those of a Spartium. The plant referred to is about four feet tall, but it will go to double that stature under favourable conditions. *North Wales.*

ALPINE GARDEN.

GENISTA HORRIDA.

THIS little Broom has not a reputation for free-flowering, but a specimen growing among other rock plants on a dry, hot slope has, this year, been gilded with its rich yellow blossoms since early July. The plant is about a foot across and half as high, making a firm, well-rounded cushion of closely-set, spiny twigs and small, trifoliate leaves, the whole shrub being downy with silvery hairs. The flowers, which are borne in terminal clusters, show up well above the branches, and if the plant could be relied upon to bloom more regularly, it would be a valuable addition to our rock garden shrubs, if only on account of the lateness of its season.

In any case, G. horrida is always worth a trial, for it is an interesting species, and its hummocky shape is admirably adapted for association with rocks and dry, sunny ledges. Its native range is mainly confined to the mountains of central Spain, upon which it grows at elevations of at least 4,000 feet. This doubtless helps to explain its extreme hardiness as compared with some of its southern allies. *J.*

CAMPANULA ROTUNDIFOLIA VAR. ROBSONII.

In the autumn of 1897, I acquired a plant of Campanula Robsonii, which I saw offered as a development of C. rotundifolia, that widely-spread species which gives numerous geographical and other forms, some of which are not constant under cultivation. The plant in question was stated to have "immense violet bells on nine-inch stems." It flowered last year for the first time, and I was much pleased with this fine form of our native Hair-bell, the "Blue-bell" of Scotland. It flowered freely, and produced very handsome, violet bells, drooping from the slender stems.

This year, however, C. r. var. Robsonii has surpassed itself, and at the time of writing, early July, is exceedingly fine. The fair-sized plant has literally hidden its foliage by the mass of flowers; it is situated near the base of the rock garden, and is most pleasing.

I have no record of its origin, but imagine it to be a wild form collected abroad and distributed a few years ago.

GERANIUM PYLZOWIANUM.

MANY good plants are found among the Geraniums, or Cranesbills, both for the border and the rock garden, and during recent years we have had some most useful and delightful introductions, one of which, Geranium Pylzowianum, came into flower with me in June and should give pleasure for a long time with its wonderfully large and brilliant flowers on a dwarf plant, not more than three inches high, and frequently an inch less than that. Mr. Farrer stated of it that it "stands eminent among the most precious of my introductions." Higher praise it could hardly have than that. It comes from grassy areas in the northern marches of Tibet.

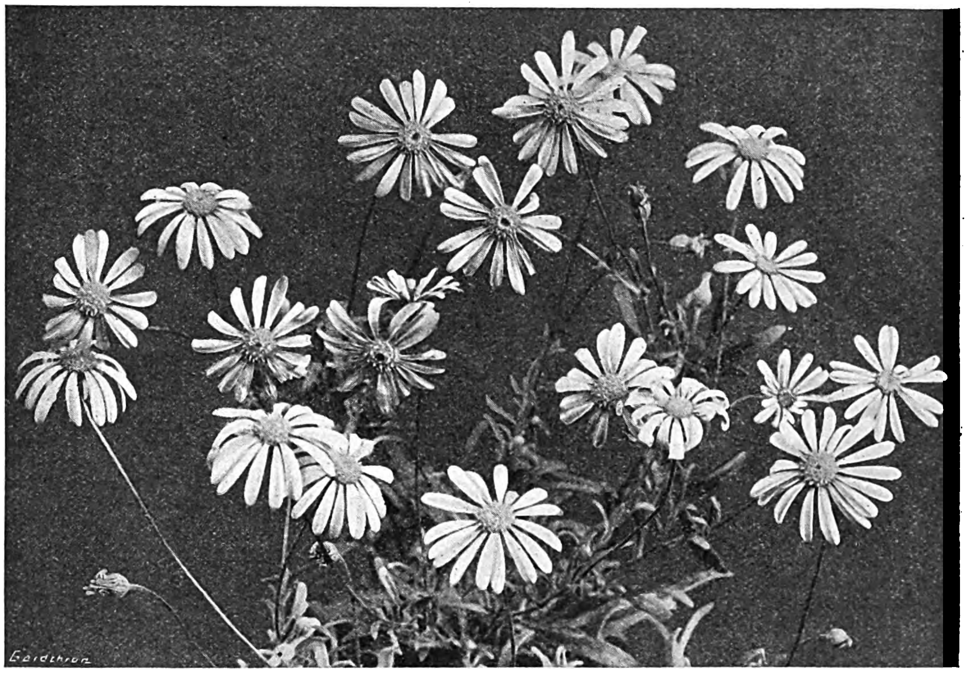

FIG. 25.—ASTER ADFINIS.

R.H.S. Award of Merit, July 9. A South African half-hardy annual. Flowers rich blue and yellow. Shown by Messrs. Sutton and Sons. (see p. 35.)

G. Pylzowianum is inclined to run about, although not at all rampantly, but with restraint, forming wide tufts of charmingly divided leaves and producing twin flowers on slender pedicels. The flowers are wonderfully large, being bigger than those of G. sanguineum. The description of the colour of the flowers is a matter of some difference of opinion. While Farrer states that it is "of a clearer purer rose than G. sanguineum," some are bold enough to call it "magenta," which it is not quite. Farrer's description appears nearer to my own ideas of the tint; in any case, it is a delightful little plant. *S. Arnott.*

CHRYSANTHEMUM CORONIPIFOLIUM.

THIS charming little alpine has been a picture of dainty beauty on the granite "Treasure Box" for the past few weeks. These dwarf Chrysanthemums (or Leucanthemums, or Pyrethrums, or Chamaemelums !) are fascinating subjects for the choice rock garden and scree, for almost all of them are of easy culture, although sometimes short-lived; they should be far more widely grown, for their flowering period is lengthy, their habit good, and they are never invasive.

C. coronopifolium, which I had as C. alpinum (a still smaller plant, and of rather frailer habit) forms most attractive tufts of glossy green, unevenly-toothed leaves about an inch high, and in June and July the six-inch flower stems arise, each bearing sturdily aloft a densely white and perfectly shaped, single Chrysanthemum, golden eyed, and of a good substance.

It is stated to dislike lime, but I have grown it equally well in both limestone and granite scree, although I somehow seem to instinctively plant it in lime-free soil for stock purposes; this is probably only an ingrained prejudice, through so often hearing it decried as a limestone plant.

Another treasured dwarf Chrysanthemum is C. hispanicum, perhaps not quite so "wee" but small enough to warrant admission to the choicest rock garden; it studs the high screes and shingle slopes of the Sierras of Spain with its downy, jagged, silvery foliage. The flowers are borne erectly on stems six to nine inches high, and may vary from white to delicate sulphur-yellow, and there is stated to be a purple form, the sight of which I hope to be spared, for I cannot picture it as being anything but frankly ugly.

C. hispanicum var. radicans is of intense charm, a Liliputian, its bright, silvery cushion being studded a few inches above with solidly round, white or yellow "Daisies." This last, however, I have always found hard to keep; it thrives for a year or two, and then, it is not ! and I have to sow seeds again; but it is easily worth the bother, for seeds germinate readily, and I am always hoping to get a permanent form, or to find a position where it will dwell happily *ad infinitum. Will Ingwersen, The Birch, Sharpthorne, Sussex.*

GERANIUM CELTICUM.

THIS has been distributed under the name of G. Robertianum var. Buxton's White. It was, I believe, distributed by the late Mr. Charles Buxton and was for long known only as a form of the native Herb-Robert.

It is now recognised, however, as G. celticum and is quite distinct from what a white form of G. Robertianum would be. It is much dwarfer and forms a very compact plant with finely divided, light green foliage, and numerous small white flowers. I believe it to be a perennial, but, in any case, it seeds freely, and soon becomes plentiful, although not producing seedlings so lavishly as G. Robertianum. With me it is only three or four inches high and, although showy, is yet quite attractive and worth growing. *S. A.*

NOTES FROM KEW.

FOR mid-summer and early July flowering, the Philadelphuses or Mock Oranges are, perhaps, the best known of all hardy shrubs, being suitable for both large and small gardens. The one drawback is that the choice of colour is so very limited. There is, however, a very wide range in the size of the bushes, while the flowering season is long, and the group embraces both large and small, and double and single-flowered sorts.

Several of the species should still find a place in a wide selection of the best ten or twelve for garden decoration, although for freedom of flowering and general value in gardens the hybrids must predominate. Arranged in their order of value, the most notable varieties flowering at Kew might be placed as follows :—Virginal, a large double white, average height five to six feet ; Voie Lactée, a very large, single white, bushes spreading in habit ; Norma, another large, single white, upright in growth ; Glacier, free-flowering, double, snowy-white and of moderate sized bloom ; Girandole, very free-flowering and fragrant, double white ; purpureo-maculatus, white, with a large blotch of purple at the base of each petal, very fragrant and abundant flowering ; Lemoinei var. erectus, a small, free-flowering, old hybrid of upright growth ; microphyllus, small flowers and foliage, very fragrant, white blossoms, the plants being twenty-four to thirty inches high, and of spreading habit ; Avalanche, free-flowering, single white ; Rouge Red, distinct, with deep crimson blotches at the base of the white petals ; latifolius, a tall, spreading bush, twenty feet high and through, with large, single, white blooms ; and insignis, a tall, late-flowering, single variety.

The Washington Thorn, Crataegus cordata, is one of the most distinct and useful of the American Hawthorns. Although first introduced to British gardens so long ago as 1738, the tree is comparatively little grown. Its valuable characteristics are that it flowers in early July, and the small, scarlet fruits, usually borne in profusion, remain on the trees throughout the winter.

Aesculus californica, the Californian Buckeye, or Horse Chestnut, is another distinct, July-flowering tree. It forms a short trunk, but unless carefully trained in a young state, this Chestnut often takes on the character of a wide-spreading shrub as much or more in width than height. The leaves are rich dark green in colour, abundantly produced and smaller than in most of the Chestnuts. The white flowers are borne freely in erect, cylindrical panicles, and the trees usually mature plenty of seeds, which provide a ready means of increase.

Sheltered by tall Oak trees in the wood on the south side of the Cedar Vista, and partially shaded from the sun by trees on the mound near King William's Temple, a considerable number of large bushes of Rhododendron discolor are flowering freely. The large, blush-tinted, white blossoms are very attractive and pervade the air with their delicious fragrance. A native of west and central China, and first introduced by Mr. E. H. Wilson in 1900, the more familiar one becomes with this Rhododendron, the greater is one likely to appreciate its undoubted merits. A perfectly hardy shrub, with large, leathery, evergreen leaves, it starts into growth late, and the flowering season of the different forms extends from mid-June to the middle of July or later. In addition to the individual value of the best forms, R. discolor, crossed with the later-flowering, large-leaved hybrids, is proving a most useful parent in the raising of a midsummer-flowering race of Rhododendrons. The most important point to remember in selecting positions for planting is that during the second half of June and in July we expect the sun to be at its brightest ; therefore, choose positions sheltered from the sun for several hours during the middle of the day.

In contrast to the large leaves and large flowers of R. discolor, there is the small-leaved and small-flowered R. micranthum. As a matter of fact, this small-flowered, white Rhododendron in general appearance more closely resembles Ledum latifolium than a typical Rhododendron plant. R. micranthum is a very hardy species and the bushes are freely clothed at the present time with compact racemes of small, white flowers. Growing three feet to five feet or more in height, R. micranthum was first introduced by Mr. E. H. Wilson from western Hupeh in 1901.

The Spanish Broom, Spartium junceum, is a very old garden shrub which cannot very well be planted too freely in light soils and dry, sunny positions. Flowering from June to September, it is one of the most valuable of all shrubs for mass planting in thickly populated town parks. The rich yellow, Pea-like blossoms are borne freely in loose, terminal racemes. The shrubs ripen seeds freely, and these provide an easy and rapid means of increase. Inclined to be loose and straggling in habit, Spartium junceum should be pruned freely each year in February or early March, especially during the first few years, or this south European shrub soon becomes unkempt in appearance.

Styrax japonica is the most useful and attractive of this interesting family of shrubs or small trees. One specimen at Kew forms an attractive lawn deciduous tree some fifteen feet high. Better conditions for the Styrax, however, are found in the shelter of large lawn beds and shrubbery borders, where there is cultivated ground and shelter to the roots provided by dwarf shrubs. In common with many shrubs this year, Styrax japonica is flowering with more than usual freedom, having come quite unharmed through 20° to 25° of frost on several consecutive nights. The pure white flowers, each about three-quarters-of-an-inch in diameter, are borne in pendulous clusters along the branches.

It is useful and interesting to note the Deutzias which withstood the hard and very trying winter well. The hybrids of D. scabra are the most useful, as they start into growth later than D. gracilis, and therefore escape the late spring frosts. Among the most satisfactory are D. scabra var. staphyleoides, single white ; var. Pride of Rochester, tall, double white, with a tinge of purple ; var. magnifica, with long, arching growths of single, white blossoms ; D. discolor var. major, with blush-tinted, white flowers an inch across, borne in long, arching sprays ; and D. Wilsonii, a strong-growing Chinese species, flowering at the end of June and early July, its large, white flowers being produced in corymbose panicles. *A. Osborn.*

NOTES FROM A WELSH GARDEN.

WHILE most shrubs have been unusually prolific of blossom, the Cistuses are not nearly so good as they generally are at this season. The winter, of course, seriously reduced their numbers, but even those which came through the ordeal with the least visible harm are yielding blossoms which are pinched and poor in form. C. ladaniferus var. immaculatus, however, by no means the hardiest and perhaps the handsomest of the genus, is doing well, and a young plant of C. populifolius var. lasiocalyx has already proved to be what the generous donor of it stated it would be—a great improvement on the type. Another uncommon Cistus, as yet only in its second season here, is C. villosus var. albus, a genuine albino form of the species.

A remarkably beautiful shrub that can always be relied on to flower freely in July is Deutzia corymbosa, a Himalayan species introduced a century ago, but not often seen. Its robust, yet elegant habit, large panicles of snow-white flowers with a Hawthorn fragrance, and its reliability and hardiness, should commend this shrub to a wider public. Another Himalayan, but of more uncertain reputation, is Abelia triflora. This deciduous species is quite hardy, but I had had it for so many years without a sight of a blossom that the present season was intended to be its last. However, it has earned a reprieve at the eleventh hour by producing its clusters of tubular, rosy-white blossoms, which, if small, are very sweetly scented. That excellent species, A. Schumannii, has been full of flower since early June, and some young plants of A. floribunda, best and probably the tenderest of all the more showy kinds, are hung with clusters of their long, crimson trumpets. In much the same colour are the Pea-shaped blossoms of Hedysarum multijugum, flopping over an old wall with that untidy looseness of habit that can be the very embodiment of grace. Lithospermum intermedium is draping the stones of a cooler part of the same wall with its glossy, fresh green leafage and masses of blue bugles. Philadelphuses are flowering with their customary vigour, and of the larger sorts grown here, P. Virginal, P. Fantasy and P. Voie Lactée always seem to stand out with distinctiveness and quality, including a refinement of fragrance which has been overlooked in some of the tribe.

Perhaps the most beautiful shrub of the season is Genista virgata, an old bush of twelve feet high and nearly as much across, having been a most arresting object for the last week or two. The soft yellow of its innumerable flowers melts into the flossy silveriness of its foliage with a soft and delicate effect of the utmost charm, and to this colour and unsurpassed elegance in its manner of growth may be added a fresh and delightful fragrance. Rosa moschata also marks the coming of full summer with the bountiful trusses of deliciously-scented blossoms which this magnificent old species will yield with such splendid generosity wherever it can be granted sufficient space. R. lucida and R. nitida also do very well in this dry, hot soil. They follow the R. rugosas in flowering, and R. nitida, grown in a thicket in a sunny spot in the woodland, makes a fine blaze of autumn colour later on. Rhododendron viscosa and R. occidentale come to wind up the season of their kind with Honeysuckle-scented, white or rosy flowers, and the Kalmias of the K. angustifolia type are covered with their rose-crimson clusters. Abutilon vitifolium did not only survive the winter, but it has been flowering well for the past month. Moreover, this very lovely shrub has produced self-sown seedlings, never before seen here, and these also must have come through the frost, for they were sturdy plants of some six inches when first noticed in spring.

One plant of Lathyrus nervosus (Lord Anson's Pea), raised from seed kindly sent me last year by Mr. F. Stewart Sandeman, has produced several clusters of bloom, and these have set seeds which promises to ripen. Susceptibility to frost is, presumably, not one of the troubles of this rare species, for the above plant, in spite of its evergreen growths, endured the winter without injury, while many things usually considered hardy were all but killed in the same border. The flowers of this specimen are a rich purple in the opening bud, the full bloom, one inch across, retaining the same colour on the standard with a paler lining. The wings are a delicate bluish-lavender, and the keel almost white, with lavender shadings.

Primula Florindae is a plant possessing so many attributes that I cannot share the opinions of any who profess to dislike it. In sun-dappled woodland shade, its stately, bright yellow flower heads against Ferns and the water, it is superb. Moreover, it comes at a season when most Primulas are getting over and strong plants will continue to put up their noble trusses of Cowslip-scented blossoms until autumn. P. Florindae is, however, a species for average rather than fat living, it being most attractive when of moderate robustness. Cathcartia villosa follows most of the other Poppyworts as a woodland plant of distinction, its straw-yellow blossoms making a useful colour-break among some of the blue and purple Meconopses. Two shade plants which, if they have not particularly striking flowers, possess an ornamental foliage and a willingness to prosper and bloom late under the drippiest of trees, are Saxifraga tellimoides and Patrinia palmata.

Among rock plants there are few things here at the moment more "distinguished" in appearance than Aster Farreri whose big, shaggy flowers, with their drooping rays of violet and bulging orb of gold, will assert their individuality among any number of rivals. Erigeron caucasicus, for which I have to thank Mr. Ingwersen, has proved itself not only a very charming plant, with flowers of a delicate rosy-lavender, but it is one of those non-stop flowerers which start early and finish late. To the same firm, I am indebted for an introduction to Morina kokanica, and all who have an affection for the old Whorl-flower will appreciate the elegance and refinement of this new species. Hieraciums have a reputation for troubling gardeners as well as botanists, but H. bombycinum, which hails from Spain, has just passed a second season here with nothing but honour to its name. This is a well-behaved Hawkweed with leaves and stems iridescent as spun glass, large flowers of a brilliant yellow and a most commendable habit of preserving intact its rounded "clocks" of seeds until you are ready to go round to gather them.

An exceptionally dry slope, having been deeply worked and supplied with a sub-stratum of retentive material topped with shingle, now presumes, with some success, to be a dry moraine. An occasional soaking in very droughty weather is all it gets in the way of applied moisture. A good many plants which had not been very satisfactory elsewhere are flourishing here, and among them is Campanula barbata, its upright stems hung with bearded bells. Androsace glacialis has struggled into flower and survived the effort. Sedum Praegerianum has tipped the ends of its red cart-wheel growths with pink and white, and the beautiful Bellis rotundifolia var. coerulescens is particularly happy in its new stony home. Scutellaria alpina and the grey-leaved S. orientalis are also doing famously. Stachys corsica, having at last found a refuge from slugs, is making quite a broad mat of its glossy foliage which is studded with pale pink flowers. Aethiopappus pulcherrimus is bearing a sheaf of its fringed, rosy-pink coronets above its finely-cut silvery foliage, and the gold of a Levantine Composite, Odontospermum maritimum, is rivalling the lustrous splendour of Helichrysum bracteatum. In contrast with these, one has the delicate pink of the elegant Chrysanthemum Mawii, the papery-whiteness of Linum monogynum, the pearl-pale cups of L. salsoloides var. nanum, the moonlight pallor of Hypericum olympicum var. citrinum, and the cold white stars of Helipterum anthemoides—a Tasmanian which has proved quite hardy. Rubus parvus has only just gone out of flower at the brink of this sham moraine, and where the Dianthuses are going over are appearing the shrimp-pink blooms of the lovely Acantholimon venustum, and the white flowers of Acanthophyllum spinosum, hovering over their spiny, grass-green pads. Hypericum crenulatum with its fragile daintiness, Geranium argenteum and the beautiful Onosma albo-roseum, are also among those which promise to do well with this shingle treatment. *A. T. Johnson, Ro Wen, Conway, N. Wales.*

GARDEN NOTES FROM SOUTH-WEST SCOTLAND.

JUNE has been a blazing month, extinguishing the flourish* on almost all late-flowering species of Rhododendron, but leaving four at their best to benefit by the refreshing showers of July.

It is well nigh two hundred years since R. maximum was brought to this country from what is now, but was not in 1736, the United States. Linnaeus gave it a specific name, not foreseeing the discovery of Asiatic giants. One does not often meet with it now in British gardens; more's the pity; for a ten-foot bush well set with neat pink or white trusses is a refreshing sight after mid-summer. Another American species, R. viscosum, belonging to the Azalea section, is a charming thing when set with its fragrant clusters of white or white and rose flowers, which, here, are at their best in early July.

Very different from these in dimensions is R. charitostreptum, which we owe to Captain Kingdon Ward, who collected it in 1919, and described it as one of the prettiest dwarf Rhododendrons he had met with. Flowering here for the first time in June this year, that verdict is confirmed by the quality and texture of its lemon-yellow flowers with red anthers. It belongs to the Campylogynum series.

In splendour of colour, none of these may compete with R. Griersonianum, which takes high rank among the many fine things we owe to Mr. Forrest. Here it comes in late June to the best of its long spell of flowering, and whether viewed afar or at close quarters its radiance is superb. Let no flare of Oriental Poppy or vehement crimson Paeony be allowed to clash with the roseate-orange of its great blossoms!

Many trees and shrubs flower at their best only in alternate years. The common Laburnum, L. vulgare, for instance, overtaxed its strength in 1928, and has taken it very easy this year; whereas L. alpinum, commonly known as the Scotch Laburnum, never fails to drape its boughs with the same profusion of long, golden tresses. One day lately, while in a certain famous botanic garden, I longed for a Kodak when a group of botanists were crouching close and stooping round a rare exotic some five inches high, while just beyond them towered a lofty Scotch Laburnum in full bloom, for which familiarity had bred, assuredly not contempt, but temporary indifference.

Some of the Olearias cover themselves with equal abundance of blossom year after year. The display on large bushes of O. macrodonta at the time of writing is amazing, considering the tax imposed annually on the constitution of the plant in producing millions of billions of Daisy-flowers and ripening seeds thereafter. Earlier in the season O. nitida and a little later O. ilicifolia cover themselves with a similar cloud of bloom.

It is more than fifty years since I brought home from the Engadine a root of Centaurea Rhaponticum, a fine species which I have never happened to see in any other British garden. It is a meet companion for C. macrocephala, being of the same height and bearing flowers of similar size and shape, but of a good pink in contrast with the other's yellow. I have never found ripe seeds on it, but it lends itself to increase by division.

Gardeners and amateurs who are alike already indebted to the firm of Rolcut for their introduction to the only perfect form of secateur, will find the tool named "Culterhoe" from the same source, a most effective implement. It is specially fitted for loosening surface soil among Roses or in mixed borders, without injuring the roots of plants. *Herbert Maxwell, Monreith.*

THE GENUS PRIMULA.

(*Continued from p.* 34).

PALMATA (Hand-Mazz.). Palmate P.
(Cortusoides-Geranioides).

A SLENDER, stoloniferous, herbaceous perennial species, with the creeping stolons or rhizomes clothed with minute, triangular scales, furnished with rust-coloured wool on the inner surface. Leaves pale green, rounded, half to three-quarters-of-an-inch across, divided into from five to seven segments, which are again divided into from two to three lobed, or coarsely toothed, segments. Umbel of a few bright rose-coloured flowers, on stalks one-quarter to five-eighths-of-an-inch long. Corolla about five-eighths-of-an-inch across, divided into five broadly heart-shaped lobes, waved and bluntly toothed at the tip; tube slightly longer than the calyx, with a ring in the mouth. Flowers in July and August. Not in cultivation.

Grows in shady places on the mountains near Sungpan, in north-western Szechuan.

Culture: Loose Oak or Beech leaf-soil and a little fibrous loam, in a cool shady spot, are the conditions indicated.

PARRYI (A. Gray). Parry's P.
(Nivales).

This handsome species produces a large tuft of fleshy, narrowly egg-shaped-oblong, blunt or rather pointed leaves six inches to eight inches long, stalkless or narrowed into a broad stalk; margins obscurely toothed or entire; both surfaces smooth or covered with minute down. Flower stem stout, six to eighteen inches tall, bearing an umbel of six to twelve bright purple blossoms. Corolla one to one-and-a-quarter inch across, divided into five broadly heart-shaped, notched lobes; tube cylindrical below, dilated upwards, longer than the calyx. Introduced in 1865. *Gard. Chron.*, Vol. LXXXI, Fig. 16, p. 27, 1927. *Bot. Mag.*, t. 6,185.

Grows on the banks of rocky, alpine streams in the Rocky Mountains, from Colorado, through Nevada, to Arizona, at from 8,000 to 13,000 feet above sea level.

Culture: Rich, somewhat heavy loam, kept moist when the plant is in growth, but well drained in winter, and a half shady spot, may suit this not easily-grown species.

PARTSCHIANA (Pax). Partsch's P.
(Carolinella).

A somewhat robust perennial species with a tuft of papery, rounded or oval-rounded, blunt leaves six to eight inches long and four to six inches wide; they are deeply heart-shaped at the base and are borne on slender, winged stalks six to eight inches long; margins furnished with coarse, blunt teeth or nearly entire; upper surface smooth, underside furnished with rusty down on the nerves. Flower stem five to six inches tall, clothed with rust-coloured hairs. Flowers in a short raceme or elongated umbel, sub-pendulous. Corolla rose-coloured, about five-eighths-of-an-inch across, divided into five nearly square or broadly heart-shaped, very deeply notched lobes, with a small, sharp tooth in the cleft; tube cylindrical, minutely downy, about three-eighths-of-an-inch long. Hook. *Icon. Plant.*, t. 2,775.

Grows in damp, shady places on the Mengting Mountains, in Yunnan, at about 7,000 feet above sea level.

Culture: As for P. megaseaefolia.

PARVA (Balf. f.). Variable P.
(Obconica).

This handsome, deciduous perennial is considered to be a sub-species of P. obconica; it has a woody, somewhat elongated rootstock, clothed with the dried remains of previous seasons, leafage. The thick, glaucous leaves, produced in tufts, have nearly circular blades half-an-inch to two inches across, heart-shaped at the base, borne on slender, hairy stalks from one to six inches long; margins edged with fine, blunt teeth; upper surface clothed with short, stiff hairs; underside with hairs on the veins. Flower stem immersed in the foliage, from half-an-inch to one-and-a-half inch long, hairy, bearing an umbel of two to five pink or lilac blossoms on more or less hairy stalks. Corolla about one inch across, with broadly heart-shaped, notched lobes; tube about half-an-inch long.

Grows in the dry clefts of limestone rocks near Yunnanfu, in Yunnan, western China, at 7,000 to 9,000 feet above sea-level.

Culture: Treat it as a greenhouse plant, and grow it in a compost of loam, leaf-soil and limestone chips.

PATENS (Turcz). Rock P.
(Cortusoides).

A desirable deciduous, perennial species formerly known under the name of P. saxatilis (Kom.), and closely allied to the well-known P. cortusoides. It forms tufts of oblong, or broadly oblong-oval, blunt leaves two to three inches long, somewhat heart-shaped at the base, borne on stalks two to four inches long; margins cut into large teeth or small, crisped lobes, or at times nearly entire; both surfaces coated with fine hairs. Flower stem six to ten inches tall, clothed with fine down, or nearly smooth, bearing an umbel of one to ten deep rose or rose-violet blossoms on fairly long stalks. Corolla about three-quarters-of-an-inch across, divided into five heart-shaped, trilobed, notched segments; tube cylindric, more than twice as long as the calyx. Flowers from March to August. Introduced in 1806.

Grows in clefts in rocks and on their surfaces, in humus and moss, in the Altai, Alascham and Amur mountains, and those of Mandschuria and northern Korea.

Culture: Fibrous loam, peat and sand, in a cool damp spot in the rock garden should suit it; it thrives in a limestone moraine. *A. W. Darnell.*

* Good Lowland Scots for blossom, adapted, like many other words in our dialect, from the French *fleuraison*.

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

PROBLEMS OF PLANT LIFE*

IV.—Concerning Mendelism.

IT would almost seem to be a natural law that the pioneer should be prohibited from enjoying perfect recognition in his own life-time. In biological research one meets with numberless illustrations of this. It is the penalty one has to pay for getting ahead of the general army. The discoverer has often to be himself discovered. But Nature is endowed with a sense of poetic justice, and seldom fails in the long run to rescue her worthy sons from oblivion. To this law Mendel was no exception. It would be a nice subject for discussion to what extent it was well or ill for Darwinism that Mendel's researches were buried out of sight during the days when the Theory of Descent was being worked out by Charles Darwin. For my own part, I think it was well. Darwin was so fair a student that he would have seen the best side of Mendel's work, and would have been tempted to think it not worth while to work out his own theory. Thus we should have been left in large measure deprived of the original researches of Darwin on these lines, and should have had to sustain the loss of his independent point of view, and his interpretation of the phenomena of heredity. Even although it has meant that the lustre of Darwin's name has been dimmed in the eyes of many, particularly those who never accepted his view-point, and rejoiced when it had to be readjusted, yet it is ever a healthy thing to be compelled to look at matters from different points of view.

Before we take up the question of Mendel's own researches, however, we have to give a glance at his predecessors, and see how once and again there was an unconscious foreshadowing of his great discoveries. It will suffice, perhaps, if we take the work of Leeuwenhoek as our point of departure. He was born in 1632, and lived for upwards of ninety years, dying at Delft, his birthplace, in 1723. He held the male element to be active while the female is passive, and that while the actual life comes from the former, the latter merely provides nourishment and the means of development by the agency of the egg. To establish his theory he took a pair of rabbits of different colour. Thus, by mating a grey male with a white female, he secured offspring which were grey like the father. This seemed conclusive, although we now know that if he had carried his experiment further a different result would have been attained.

Passing by some other experimenters, we come, after the middle of the eighteenth century, to Felix Vicq d'Azyr, who was born at Valogne, Normandy, in 1748. He experimented with Tulips, and found that if he crossed white with red, the descendants were white, red and intermediate. This was a step in advance of Leeuwenhoek, and is a clear foreshadowing of Mendel's results, although not carried to the logical conclusion. Kōlreuter is another biologist whose name must be mentioned in this connection. We are told that "for a number of years he crossed different types of Tobacco plants with one another, afterwards, however, proceeding to other plant genera: Pinks, Aquilegia, Verbascum and others. Moreover, he was able to vary his experiments and note the results. He carefully compared the hybrids with the parent individuals and noted the similarities and dissimilarities between them. He mated the hybrids with their parent species and observed the reversion to similarity with the latter. Further, he fertilised the hybrids with one another and obtained results which foreshadowed Mendel's famous observations." But although he did all this, and even noted crosses which at the present day would be regarded as mutations, he failed to utilise the results of his experiments. This was largely due to the views he held respecting fertilisation. Thus he believed that if a species were fertilised with a mixture of its own and foreign pollen it would be possible to obtain a sort of semi-hybrid which would closely resemble the mother species. In spite of this lapse, his methods came to be regarded as the model for such investigations, and held the field until they were supplanted by those of Mendel himself.

It will thus be seen that the way was being gradually prepared for a master mind, leading up to the investigations which were simultaneously carried out in this country by Darwin, and on the Continent by Mendel. To the latter, therefore, we now devote our attention. Mendel who was born in 1822, was named Johann, but in later life adopted the name Gregor. He early showed signs of unusual intelligence, and at the expense of the monastery, of which he became an inmate, at Brünn, in Moravia, was sent for three years to Vienna. On his return he took up educational work, devoting his leisure hours to the scientific study of plants. The results of his researches were not published in any of the well-known scientific journals, and it was on this account that, in spite of their importance, they were hidden for many years from the eyes of experts. The fruit of much research was gleaned in two short essays which were issued in the *Journal* of the Natural History Society of Brünn. These papers show at once a keen appreciation of nature and a thorough knowledge of mathematics. To begin with, Mendel selected certain well-marked characters, such as the colours of the flowers, the structure of the blossoms, the shape and characteristics of the seeds, and studied the results of intercrossing through several generations, until he discovered the laws which underlie their changes and mutations. Thus, for example, he crossed Sweet Peas which bore red flowers with those which were white, and Peas which were wrinkled with others whose skin was smooth, with the result that he found out that they had characters which he designated dominant and recessive.

The rest of the story is well-known. One has only to read the works of Bateson, Punnett, Morgan and others to see how fruitful of suggestion the Mendelian results have proved. These researches have been carried beyond the nursery. Originally undertaken as a special study in plant phenomena, they have been applied with equal success to various forms of animal life, and are even bearing fruit in the realm of eugenics. With their relation to Darwinism we need not concern ourselves. The work is still going forward, and already a considerable library has been formed by the study of Mendelism alone. Of all the problems of plant life, none is more fascinating, and of few can it be stated that their solution has yielded more important results. *Hilderic Friend.*

SOME GARDENING FALLACIES, ANCIENT AND MODERN.

Students of evolution tell us that the dog's habit of turning round and round before settling down to sleep is a survival of the period when its canine ancestors had to shape their bed out of the dense jungle grass. The habit persists, although the necessity for it has disappeared.

A similar explanation may account for a like persistence of ideas that are not based on facts, or any logical deductions therefrom. It will be interesting to study some of these facts from the gardening point of view. Many of them are mere superstitions, but they are, nevertheless, a serious bar to progress. In one form or another these fallacies clog the efforts of the would-be scientific gardener. They account for many of the whimsical opinions of employers, for the fixed determination to do things the wrong way on the part of underlings, and for the inexplicable vagaries of the suppliers of horticultural tools and requisites.

If only one of these fallacies is killed as a result of this article, it will not have been written in vain.

One of the commonest fallacies of the countryside is that a profuse display of berries foretells a hard winter; but the most elementary observer of plant life knows that the berries are the result of past growth and flowering conditions. Yet similar fallacies exist even among educated people who have their letters accepted by the *Times*. For example, a *Times* correspondent recently attributed this year's profusion of flower in the genus Pyrus to the severity of last winter, but it is well-known that the embryo flower bud is produced too early for winter frost to have such an effect. It is true that winter frost, enforcing a period of rest, has an influence—but this influence is not the creation of flower buds to increase profusion of blossom.

A fallacy which seems to exist even in gardening circles is that Mustard and Cress requires to be sown in fine, rich soil to produce a suitable salad. But the seeds contain nourishment sufficient for the plant until the cotyledons have reached the stage when they are useful for salad. Soil is therefore useless, indeed a handicap, as it fouls the produce with grit and prevents access to the maximum amount of water that is beneficial. The best medium is flannel or similar absorbent material stretched tightly over shallow receptacles filled with water.

A number of gardeners seem to be governed by fallacies about mulching. This is a practice which may be as harmful as beneficial if not applied with judgment and intelligence. For example, mulching early in the spring when the ground is cold will prevent the access of the sun's warm rays and the escape of excessive moisture. The same kind of mulch applied later, when the soil is warm, will conserve the necessary moisture and assist growth. Again, many growers apply fresh farmyard manure in the autumn as a protective mulching and especially in the case of Roses. Apart from the debatable point as to whether or not Roses need protecting in winter, it is obvious that a plaster of heavy farmyard manure will keep the ground wet and cold. If protection be needed, a loose covering of dry Bracken will be more effective and will have no undesirable effects.

Many fallacies about watering plants persist, especially among amateur gardeners. Some assume that, following the example of the frequent shower, it is desirable to give plants a little water every day during a long drought. This method encourages surface rooting, and such roots as are attracted to the surface perish for lack of moisture in the fierce heat of a summer day. If water is applied, a thorough soaking should be given, followed by a mulch or the use of the hoe.

The old fallacy that weeding makes soil too dry in the summer is fast disappearing, and the value of the hoe as an agent in conserving moisture is more generally recognised. In some quarters it is still held, however, that weeds are a good substitute for a mulch. This is wrong in a double sense; the weeds rob the soil of moisture for their own needs and also

---

* Previous studies appeared in our issues of April 13 (p. 279–80), June 15 (p. 446–7), Vol. LXXXV, and July 13, (p. 30).

remarkable ideas on the perpetuation of plants by seeds, and seem to imagine that our highly developed types of flowers and vegetables may be reproduced without care or effort, so that penny packets should be the normal means of distribution; but students of genetics know that seed growers have many natural difficulties to contend with in keeping their strains of plants up to the high standard of their reputation. Anyone doubting this should simply grow a few plants for seeds of any highly developed Brassica crop in close proximity with a common Turnip or Kohl Rabi, for example, and see how natural intercrossing can reduce the value of the strain.

In the matter of protecting plants, many erroneous ideas exist, one of the most common being that a blanket-like covering which excludes air has the greatest protecting power. A light covering, however, which allows air to circulate is a much better protective agent, and if the heavy cover becomes wet, the plant inevitably suffers worse than if it is given no protection at all.

Many wrong ideas persist about the hardiness of plants, and it is possible that if the subject were properly studied and understood, the loss of many valuable specimens could be averted. It is not, as is sometimes supposed, a question merely of the maximum number of degrees of frost that a plant will withstand without injury; other factors equally as important as temperature are soil, position, age and stage of growth of the plant. Thus, under favourable conditions it is not uncommon for a plant to withstand without injury 10° of frost, whereas another of the same species under a less favourable set of conditions will be killed outright by 5°. The natural hardiness of plants may be reduced in some cases by injudicious pruning of old stems by persons with too great a craze for tidiness. Undoubtedly, these, or the dried leaves they bear, are nature's protection to the plant. On the other hand, the common advice never to prune during frosty weather is probably based on a fallacy. I have consistently ignored this advice and have never traced any ill effects by so doing. The fact that market growers on a large scale never cease pruning during frost supports the view that the practice is not a cause of serious damage.

Garden tools provide many examples of fallacies, some of which seriously reduce the efficiency of the operator. For example, spades are made in three sizes, the largest of which, No. 3, is so unwieldy that the strongest man could not use it without loss of efficiency even on the lighter soils, still less on the heavy ones. The same principle applies to both Dutch and draw hoes, which are made up to ten inches wide. Apart from the impossibility of using a tool of such width with efficiency on fallow land, one would feel many qualms about entrusting such a murderous weapon to a casual worker.

It would seem that the directors of design for the leading tool manufacturers have a mathematical regard for size, but mathematics apart from all other considerations, may mislead, and it is certainly true that practical users of tools are too seldom consulted. As regards tool designers, who was the inventor of the so-called Asparagus knife, and why do gardeners use it? The unsuitability in design of many English tools is all the more to be lamented because the tools themselves are usually of high quality, in fact, they wear extraordinarily well. English knives, for example, are second to none, and even the German tree-pruner has a decided preference for the English pruning knife. But I shall never forget the language of a French gardener who, trusting to the excellency of English cutlery, sent for an English Asparagus knife as advertised; it was justified but unprintable. A more murderous weapon for use in the Asparagus bed it would be impossible to devise, even if the ingenuity of the inventor were bent wholly on destruction. Anyone sufficiently interested to dissect an old Asparagus root will find that the base of the growing head is encircled with buds in various stages of development; how many of these embryo shoots are pulled out by this saw-like instrument when attempting to cut the mature heads for consumption, is beyond anyone's power to compute. Why call it a knife; is it not a saw, and a very bad saw at that? I always use a first-class pruning knife for cutting Asparagus heads, and shall continue to do so until a more serviceable type of instrument for the purpose is introduced.

It may be argued that the purchaser should exercise intelligent selection and that this type of tool would never be produced if it were not found useful. But many amateur gardeners buy without experience, and when experience comes they do not realise, except in a vague way, the energy they are dissipating or the damage they are causing by the use of ineffective tools. Further, in many establishments, the gardener is not privileged to purchase or even select his tools, and once purchased, ineffectual or otherwise, they must be worn out in long-suffering silence. *W. Auton.*

(To be continued).

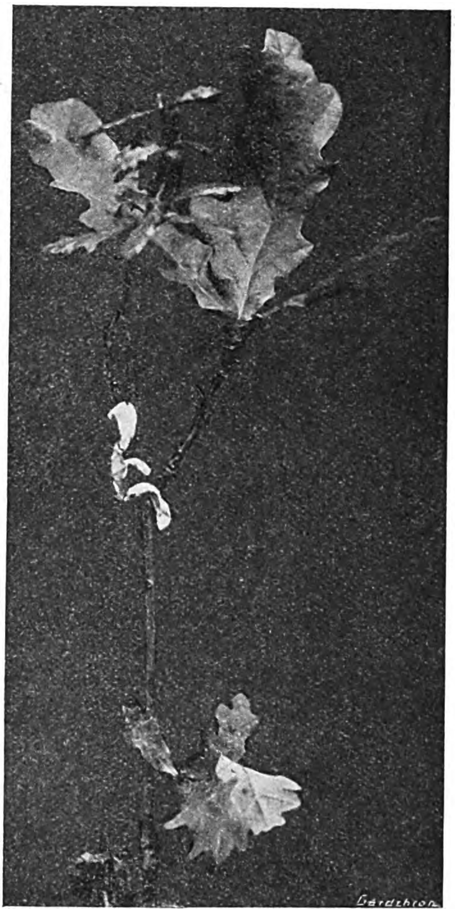

FIG. 27.—OAK MILDEW.

Primary infection; from such a centre the mildew is spread through the nursery.

OAK MILDEW AND ITS CONTROL IN FOREST NURSERIES.

A practical method of controlling Oak mildew, Microsphaera quercina, in forest nurseries has been found, and the results of detailed trials have been published in *Forestry*, Vol. III, No. 1, 1929, under the joint authorship of R. C. Woodward, J. S. L. Waldie, and H. M. Steven. The serious nature of Oak mildew in nurseries has limited the production of good nursery stock and has made the successful establishment of Oak a more difficult problem. Considerable work, entailing careful observations, during the past four years has made it possible to trace the life history of the fungus and as the result of this a new avenue of approach has been opened up for the control of the disease.

The mildew was first observed in England in 1908, and can now be found wherever Oaks are grown in Scotland, England and Wales. It appeared in epidemic form in France in 1907 and spread rapidly throughout Europe from west to east. The winter spore or peritheca stage of the mildew was not seen in Europe until 1911, and since then reports of its occurrence have been made in most of the European countries except Britain, where diligent search has failed, as yet, to reveal the presence of this form of the fungus.

The mildew attacks Oaks of all ages, but it is most serious on Oak nursery stock and Oak coppice. On nursery stock the mildew (Fig. 27) greatly retards growth, and also tends to "kill back" shoots for a considerable distance. On Oak coppice and older trees it is the Lammas shoots, or those which develop during the summer, that suffer most from the disease. When the Oaks have been defoliated by caterpillars or damaged by frost, the second set of leaves is very frequently attacked by mildew. The species of Oak which is most seriously attacked is the Common Oak (Quercus pedunculata); the Durmast Oak (Quercus sessiliflora) is less susceptible, and the Turkey Oak (Quercus sativa) is immune to the disease in this country, although in its native habitat, in southern Austria, it is severely attacked. In Britain the mildew is also found attacking the Beech (Fagus sylvatica) very often on stool shoots as well as on seedlings. The Chestnut (Castanea sativa) has been stated to be susceptible to Oak mildew on the Continent, but so far, it has not been seen in this country, even where Chestnuts were found growing in the middle of plantations of heavily infested Oaks.

It has been found that the mildew overwinters in Britain solely by means of mycelium which becomes established in the axillary or terminal buds at a very early stage in the formation of these buds. Observations have revealed the fact that the young stem itself which bears the mildewed leaves, usually becomes infected, and this often leads to the establishment of the mildew in the axils of the leaves, and in the subsequent infestation of the young axillary buds situated there. The fungus thus established within buds has been found to overwinter between the young leaf tissues in the form of mycelium. The mildew may only enter buds at an early stage and during the short period when the scales provide inadequate protection from invasion. Once infested the buds may retain the mycelium of the mildew in a dormant condition throughout the winter, and it has been found that this mycelium in the buds is revived into vigorous growth in the spring, when great masses of conidia or spores are produced on the young tissues protruding from the buds. These spores are air-borne and infect fresh foliage and other plants and results in the infection of additional buds, so that the disease is thus perpetuated from year to year.

It is to be noted that only a small percentage of mildewed plants—1·5 to 7·6 per cent.—show successful overwintering of the mildew in the buds, but this number is sufficient to perpetuate the disease, and to cause severe outbreaks when conditions are favourable for the rapid distribution of the fungus. The sources of infection in spring, then, are very limited in number, but careful scrutiny will reveal their presence. Such sources are termed primary. Secondary and subsequent infections occur later and are caused by the distribution of spores from the primary centres of infection. The virulence of secondary infections depends very largely upon the weather and environmental conditions.

In 1928, observations revealed the fact that a month or more elapsed before secondary infections became severe, although they were noted, in an inactive state, at the beginning of this period. The length of this period of inactivity undoubtedly changes from year to year, and depends upon climatic conditions largely in so far as these affect the growth of the plants and encourage the production of tissues susceptible to infection. When favourable climatic and environmental conditions obtain the mildew becomes widespread and often very severe.

There are other means by which the Oak may contract infection during spring, but in this country, infection other than that from infected buds, has not been found to occur. It has been mentioned that perithecia have been found in most countries except Britain, and where this spore stage exists it is probable that a means of overwintering is thereby provided. It seems probable that the acclimitisation of the mildew is necessary before perithecia are developed in Britain; until they occur no measures need be taken to afford protection from this source. In Italy, chlamydospores occur, and are stated to play a prominent part in the life history of Oak mildew. These spore-like bodies may be described as thick-walled swellings in the mycelium, and they are stated to drop to the ground with the leaves at leaf-fall, and to cause infection of new growths the following spring. This form of the fungus has not been observed in Britain.

Two parasites of Oak mildew are common, namely, Cicinnobolus Cesatii, de Bary, and a yellow cecidomyid larva resembling a species of Mycodiplosis. The former is thought to be of some importance in suppressing severe mildew attacks during the late summer.

Control of the Disease.

Having studied the life history of the mildew of the Oak, it was found, as already pointed out, that primary infections arising from buds infected a previous season were the only sources of infection in each succeeding year. To combat the mildew, therefore, it was seen that the prevention of the infection of buds would eliminate secondary and subsequent infections contracted from these sources. This it was found impossible to accomplish completely in one season. However, the number of primary infections was reduced by eighty per cent. as the result of one season's spraying. The routine application of sprays year after year would, therefore, greatly reduce the prevalence of the disease in the nursery. Unfortunately, the mildew may be air-borne, and Oak trees situated at a considerable distance from the nursery may provide sources of infection each season. It is, therefore, also necessary to afford protection to the nursery plants from the air-borne spores from neighbouring Oak or Beech trees.

As the result of experimentation with certain spray fluids, it was found that either colloidal sulphur, or flowers of sulphur made up as a paste with calcium caseinate, and diluted at the rate of 2 lbs. to 4 lbs. to 100 gallons, successfully prevented secondary infections, and also protected buds from infestation very satisfactorily (Fig. 28), thus greatly reducing the number of primary infections the following spring. Of the two fluids, it was found that flowers of sulphur with the addition of calcium caseinate was just as efficient, the cheaper of the two, and easily procurable. The use of calcium caseinate as a spreader at the rate of 3 lbs. per 100 gallons, was found to be more practicable and efficient than soft soap. The number of applications necessary per season varies with the growth of the Oak and the amount of infection. Under favourable conditions, one may be sufficient, but usually three to five are necessary, the first one being made when the mildew first appears. It was found that either of these treatments secure that more than half of the plants are kept entirely free from mildew throughout the season, and that there is a significant increase in the dry-weight of the plants, seventy per cent. increase having been recorded. The proportion of plants with good leaders was increased by twenty-two per cent., and thus the amount of good nursery stock was increased, and the number of bushy and unsuitable plants decreased.

Sprays, using one per cent sodium chloride (common salt) and lime sulphur burned the young foliage; flowers of sulphur as a dust was not successful, and ammonium polysulphide only partially efficient. Sheltering of the young plants did not reduce the mildew. *R. C. Woodward, B.Sc., Ph.D. (Cantab.), School of Rural Economy, Oxford.*

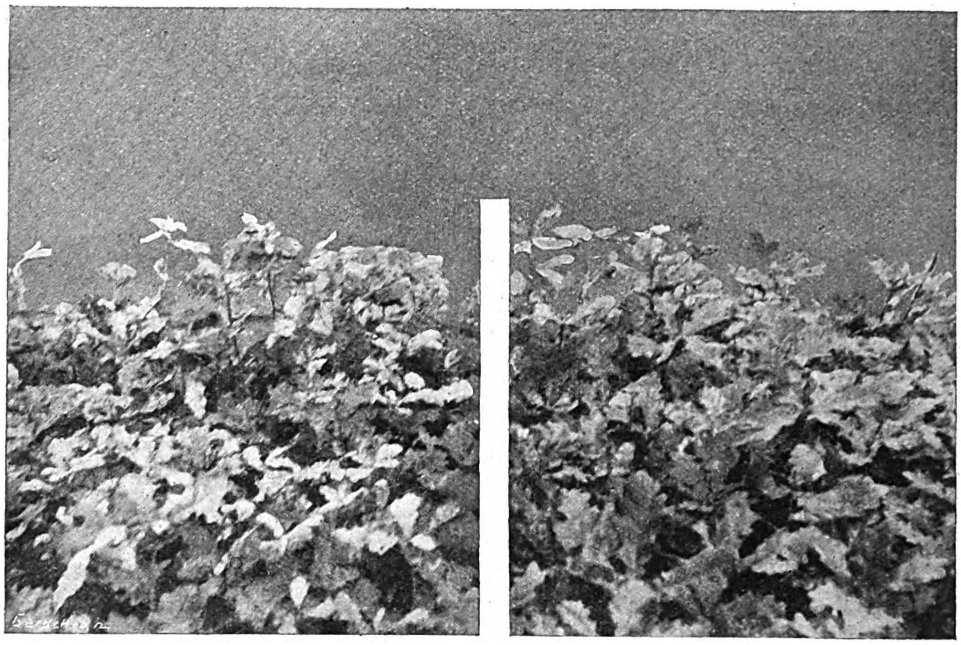

FIG. 28.—OAK MILDEW.

Left: Unsprayed. Right: Sprayed with colloidal sulphur.

MARKET FRUIT GARDEN.

June, which was so dry in some districts, had more than the average rainfall in mine, mainly because of a thunderstorm during the first week. There followed a dry period which soon drew most of the moisture from the soil; but further showers occurred at the end of the month. Nothing suffered from drought, and both tree and bush fruits are looking very well. The rain brought up the weeds in great profusion, so that we had to pay for the easy time experienced earlier, when it was sometimes difficult to find work for horses and men. A more pleasing effect of the moisture was the rapid swelling of the fruits. Apples and Plums are getting quite big; and there was a good crop of Black Currants nearly ready to pick at the end of the month.

Apples Very Heavy.

The crop of Apples is the heaviest I have ever had, and so far the best for quality. I find that, after all, there is a good crop of Cox's Orange Pippin on many trees of this variety. Blenheim Pippin is the only kind of which I have not a full crop. The set is so full, in nearly every case, that the operation of thinning is most formidable. I have four gangs at work on this, and the end seems a long way off. Without thinning, the crop would be almost useless, for there is no demand for small Apples nowadays. Some of the work is being rather roughly done, as I have had to employ any one I could get; but anything will be better than nothing. Beginners are, of course, put to thin the rougher varieties, where they cannot do much harm. Actually, their chief fault is that they do not take off enough. In some cases it means removing nine out of ten of the fruits. There are several little refinements in thinning which one likes to see observed, but cannot expect from casual hands. Naturally, the best Apple should be left to mature; but this is not always the biggest. In some varieties the central fruit in the cluster, while generally the largest, is often thick-necked and therefore unshapely when mature. I had a large number of such fruits in my crop of Cox's Orange Pippin last season, which reduced the number of specimens fit for packing in single-layer trays. Further, if there is any choice, it is well to leave an Apple which hangs downwards, because this is least likely to rub against a branch or to drop later on.

The reason for my heavy crop is not difficult to find. I expected a lot of bloom after last year's dry summer, remembering what happened after the drought of 1921. I felt so sure of it that I had extra orchard boxes and steps made during the winter. The free setting of the bloom can undoubtedly be attributed to the use of plenty of nitrogenous manure shortly before flowering. Many failures attributed to frost are probably due mainly to lack of vigour at this important time. Quick-acting and short-lasting fertilisers are the best to use, as the tree ought to be vigorous at the start of the season, and yet not carry on with growth too late into the autumn.

Pests and Diseases.

The only insect pest much in evidence in my plantations now is Apple sawfly, which is abundant in most places this year. It cannot be stated to have done me any harm, as the bored fruits are removed in thinning; but I never saw so much of it, and it seems to be an increasing pest. Spraying with arsenate of lead just as the last quarter of the petals are falling gave a good control at the East Malling Research Station, but has not given anything approaching complete immunity in my case. How much good it did do I cannot state, as no unsprayed trees were left.

Scab is still hardly to be found on trees that were sprayed only twice. The second post-blossom spray was omitted in all the older plantations on grass, as there was none of the disease showing, and it seemed a pity to risk the application of more lime-sulphur in the hot weather. The younger plantations, under clean cultivation, which are always more liable to scab, received the third spraying, the wash used being colloidal sulphur. This was chosen because it does not spot the under-crop of Black Currants.

A very good control of pests and diseases has been secured by quite a simple programme of spraying. That there was plenty to spray for is shown by neglected trees in the locality. Scab, in particular, has made a somewhat belated but formidable appearance on these; and some orchards have been entirely defoliated by tortrix caterpillars. My programme consisted of winter spraying of everything with tar-distillate. Plums had nothing more. Apples had a pre-blossom spraying with Bordeaux mixture. All received also a post-blossom spraying with lime-sulphur and arsenate of lead; and the younger plantations had the further application of colloidal sulphur mentioned above.

I believe in dilute fungicides and a fairly heavy dose. It seems to me to be essential to wet every inch of the leaves, and this cannot be done on a large scale if any attempt is made at mere dewing over. Tender varieties had Bordeaux mixture at only half strength, 4 lbs. of copper sulphate and 8 lbs. of quicklime (or 12 lbs. hydrated lime) to one hundred gallons of water; and the result is just as good as where the normal mixture was employed. Lime-sulphur was not used at a greater strength than one part in one hundred of water; and for Cox's Orange Pippin, this was reduced to one in 150, again without any difference in results. Probably, however, this was an easy season in which to control scab. Even the tar-distillate I use at only six per cent.

In some years a proportion of the fruits of Beauty of Bath has been badly russetted and even cracked. I have always wondered whether this was spray damage or weather injury. No one has been able to give me a definite opinion, and the two can be very similar. This season, I feel no doubt that the cause is weather, probably frost, because the damage occurs only in the lower part of two plantations, where frost would be likely to be most severe. In one of these spots the leaves surrounding the bloom were badly crippled by frost before any fungicide was applied. There is, this season, just a little of the roughening around the eyes of Bramley's Seedling fruits which is known to be due to frost.

New Spray Fluids.

Work of a very promising kind is being done at the Long Ashton Research Station in the making of new washes. The Long Ashton tar-distillate wash, made from "high neutral" distillate, without the tar acids, has already shown itself in trials to be more effective than the commercial brands of tar-oil wash. This year a remarkably good control of Apple capsid was obtained by the use of this wash at ten per cent. In one case an attack which spoiled eighty to ninety per cent. of the Apples was reduced to three or four per cent. I think I am right in stating, however, that these trials have all been carried out in the West of England, where, for some reason or other, tar-distillate washes have always given a better control of capsids than in the East. The wash is also rather more effective against caterpillars than the proprietary brands.

Another promising "find" at the station is a Rape oil emulsion wash, which seems likely to serve as a cheap substitute for nicotine as a contact insecticide. The latest report from the station contains an account of preliminary work with yet another wash. It has been found that the active principles present in Pyrethrum flowers can be extracted readily by means of light petroleum. The extract can be dissolved in a fatty oil, such as Rape oil, and then emulsified with Agral W.B. An emulsion prepared in this manner, representing a concentration of one per cent. of the original flowers, is rapidly fatal to insects, but causes no damage to vegetation. It is apparently not necessary for insects to be drenched with this wash, for certain beetles died when placed on leaves or soil which had been sprayed a few days previously. English-grown Pyrethrum flowers, by the way, can be employed. *Market Grower.*

HOME CORRESPONDENCE.

[*The Editors do not hold themselves responsible for the opinions expressed by correspondents.*]

Violas for Exhibition and Garden Purposes.—I do not consider the selection given in the article on Violas, by Mr. James A. Paice, in your issue of June 8 (p. 422, Vol. LXXXV), a very good one. Some of the varieties he gives for exhibition are not at all good, and are never included in exhibition stands by Viola specialists in the north. They have been superseded by much improved varieties. Again, some of the varieties he gives for garden decoration are altogether too straggly. I append a list which I consider is right up-to-date:—Exhibition Violas:—Chris. Littlejohn, Andrew Jameson, Mrs. M. B. Wallace and Mrs. Andrew Stevenson, fancies; Helen W. Cochrane, white; John Adamson, yellow; Milton Jumbo, purple; Walter Kay, blue; Admiral Hood, Moseley Ideal and May Harvey, yellow, edged lavender; and Mrs. H. J. Milner, Essie Johnston and Janet Stevenson, white and cream, edged lavender. Violas for garden decoration: Redbraes Yellow, Hallidon Yellow and Kingcup, yellow; Mrs. Airdrie and Primrose Dame, primrose-yellow; White Swan, Palmer's White and Lady Tennyson, white; Fred. Williams, Dunbrain and Mauve Queen, mauve; Violet Gem and Jersey Gem, violet; Councillor Waters, purple; Amy Barr, rose; Kitty Bell, lavender; Springwell Bronze and Redbraes Bronze; and Gladys Finlay, Jas. Pilling, Kathleen, Mrs. Marrison and Mrs. T. Douglas, fancies. *W. Thompson, Ardwick, Manchester.*

Labour Problem in Scottish Fruit-growing Districts.—The great problem facing the fruit-growing districts of Scotland during the next few weeks will be a labour one. Mr. Ralph Nunn May, the Secretary of the English National Union of Students, made an appeal in *The Gardeners' Chronicle* of June 29 (p. 479) for employment for poor students during the summer vacation. Mr. May may be interested to learn that the employment of university students during the summer has been in vogue in Scotland for many, many years. Without this aid thousands of "lads o' pairts" now filling highly responsible and influential positions would never have been able to take their degrees. In far-off days, when, for example, the late Sir William Robertson Nicol, editor of the *British Weekly*, was a student, the plan was for students to engage during the summer in farm work, but now-a-days they aspire to more congenial and more lucrative employment. Scottish university students may now be found occupying a variety of occupations, such as pursers and clerks on river pleasure steamers, waiters in hotels at favourite country resorts, and, where the job is only seasonal, relieving clerks in city offices, acting as copyholders to printers' readers during the holiday season, and inspecting gas meters and, of course, there are many who still prefer farm work; indeed, a page of *The Gardeners' Chronicle* could be filled by the many and multifarious jobs the Scottish university student turns to to enable him (or her) to overcome financial difficulties. In recent years Scottish fruit-growers have been introducing student-labour during the fruit-picking season, and they fill the rôle admirably. But there is a great fear among growers this year that the supply of pickers will not meet the demand, and be sufficient to go round. Some idea of the requirements during the short season may be gathered when it is stated that some fruit-growers will require 400 workers. The picking season is a most precarious one, for a day's delay in picking the fruits may mean the loss of hundreds of pounds to the grower, hence the anxiety in fruit-growing circles. The area under fruit has been greatly extended of recent years, and at least fifty per cent. has been added to the acreage during the last three years. How important the industry is to Scotland will be understood when it is stated that considerably over £60,000 was realised last year by the Blairgowrie district of Perthshire alone. Within recent years the district of Coupar Angus has become a formidable rival to Blairgowrie, and the erection and opening of a new factory at the former place for pulping the fruits and thus easing transport difficulties may well mean Blairgowrie ultimately taking a secondary place in the industry. The development of the industry proceeds apace in Scotland, and apart from the entry of Coupar Angus, we have Alyth, around Kirriemuir—Sir James M. Barrie's home-town—and Aberuthven districts making ambitious efforts, and wonderfully successful ones, too, to take a place in the fruit-growing sun. All these districts, be it noted, are within a few miles radius of Blairgowrie, this making Raspberry-growing and Blairgowrie synonymous terms. The wages paid to the pickers are very good, and even an inexperienced worker can earn from 7s. 6d. to 10s. a day. Of course, accommodation is provided in the chief centres, and shops and a post office find their place in the economy of things during the fruit-picking season. *W. K., Aberdeen.*

Meconopsis betonicifolia var. Baileyi.—In your issue of June 22 (p. 466), I was pleased to see a correspondent's remarks about Meconopsis betonicifolia var. Baileyi at Wisley. About a month ago, a batch of this Meconopsis flowered in the rock garden at Bellahouston Park, Glasgow, and the visitors were absolutely enchanted with it. Practically every visitor passed remarks to the effect that they had "never seen anything like it before." They were not surprised, however, at seeing something comparatively new in cultivation, for this is typical of the Glasgow Parks. There is always something fresh and bright to be seen there, so that, when the tired city worker takes a walk through them, he finds many surprises in the way of beautiful flowers, shrubs and trees. *R. C. McMillan, Ibrox, Glasgow.*

Large Magnolias.—Referring to your illustration (Fig. 218, in *The Gardeners' Chronicle* of June 8), may I state we have a Magnolia conspicua thirty-three feet in height, twenty-eight feet across, and twenty-eight inches round the trunk. It branches six feet from the ground, and has a circular and evenly balanced head. It is about one hundred years old. I have also a Tulip Tree (Liriodendron Tulipifera) seventy-six feet in height, fifty-nine feet in breadth one way, and sixty-six feet another way; this tree is more than one hundred years old. There is also a Sequoia gigantea, ninety feet in height and thirteen feet in circumference of trunk; this grows on the same lawn and is about the same age as the Tulip Tree. Your very interesting paper is always a pleasure to read. (*Mrs.*) *S. Thatcher, The Manor House, Chew Magna.*

VEGETABLE GARDEN.

LETTUCE LEE'S IMMENSE HARDY GREEN.

This useful Lettuce should be more widely grown than it is. It is extremely hardy. I had a bed of it planted out in October, 1928, under a south-west wall, and at the beginning of March last they were difficult to find. However, a good hoeing in early April and a light sprinkling of sulphate of ammonia soon caused a great change, and by the third week in May I was cutting fine quality hearts averaging about eight ounces in weight.

Seeds are best sown about mid-August. A good companion to this Lettuce is Hick's Hardy White Cos, and a well-prepared and sheltered border planted with these two Lettuces should prove of great value for providing a crop in the spring.

BROCCOLI SPITALFIELDS MARKET.

The past February provided a severe test to Broccoli, and in many cases whole breadths were killed owing to the severity of the weather.

Many growers have for years put their faith in Knight's Protecting Broccoli and, admittedly it is a grand variety, but my greatest success during the past May and June was with the variety Spitalfields Market; in a bed of one hundred plants only five were lost, whereas, with Knight's Protecting, only ten per cent. came through the ordeal, and these were all damaged.

Spitalfields Market is a rather dwarfish variety and the heads are well protected. It may be planted late (mine were put out in August) and its habit permits of closer planting than any other variety I know. Firm planting is, of course, a great factor in ensuring success. *G. W. Stacey, Chorley Wood Cedars.*

SOCIETIES.

NATIONAL ROSE.

Only once before has the National Rose Society visited Hereford for the purpose of holding its Provincial Show in that ancient city, and that was so long ago as 1891, since when the Society has grown enormously, both in importance and membership, so that the show held at Hereford, on the Castle Green, and in the shadow of the monumental Cathedral, on July 10 and 11, was a grand affair, and well worthy of the Society.

The trade was strongly represented in the nurserymen's section, and in many of the amateurs' classes the exhibits were numerous and competition keen, while the new seedling Roses put up for awards were also plentiful, Messrs. S. McGredy and Son showing a very big selection of grand sorts. The quality of the blooms throughout the show was high and competition in many instances very keen. The exhibition was held in conjunction with that organised by the Hereford and West of England Rose Society.

Gold Medals.

Mrs. Sam McGredy.—A grand Rose of dazzling colouring, glowing orange-red, shading to rich apricot, the reverse sides of the petals being heavily suffused with red. It is a shapely flower, both in the bud and when fully open, and has a great future before it.

Portadown.—This lovely Rose has already received a Certificate of Merit from the National Rose Society, and it well deserves the higher award now bestowed upon it. Of grand form, it has rich red, velvety blooms, large and full, and of grand texture; they are carried well on strong, stiff stems which are well furnished with large, dark green foliage. (An illustration of this Rose appeared in our issue of June 21, 1928, Fig. 18, p. 45.)

James Rea.—Another grand Rose, beautiful in the bud, and opening into a large, full bloom. The colour is a rich, glowing deep rose, and the arge petals are of firm texture. These three H.T. Roses were exhibited by Messrs. S. McGredy and Son.

Certificates of Merit.

Mrs. C. Aveling.—A lovely semi-double H.T. Rose of vivid colouring, the petals being a glowing orange-red, shading to yellow at the base; a striking Rose. Shown by Messrs. Bees, Ltd.

Lieut.-Col. A. Fairrie.—A beautiful Rose of delicate colouring and good form, both in the bud, which is very shapely, and when opened. It is pale cream, flushed with apricot. Also shown by Messrs. Bees, Ltd.

Molly Darragh.—A large Rose of bright colouring, the broad petals being creamy-yellow at the base, gradually shading to rich rose at the margin. Shown by Messrs. S. McGredy and Son.

Other Novelties.

Mr. George Prince showed blooms of Yadil, shapely both in the bud and when fully open, and of rich colouring; being creamy-yellow and rich orange-apricot, turning paler when fully opened.

Messrs. Frank Cant and Co., Ltd., showed three new H.T. seedlings, namely, Dorothy Hodgson, rich rose in colour; Doy, a shapely Rose, cream, tinged with palest apricot, and Rose Merk, of only moderate form but of rich colouring, being glowing red, with a slight plum sheen on the outer petals.

Marion Horton was one of the good novelties shown by Messrs. Bees, Ltd.; it is a shapely Rose, rich yellow in the bud, with orange-red guard petals, and creamy-yellow with a darker centre, when fully open. They also showed George Howarth, a large Rose of good form and vivid cerise-red colour; and Mrs. J. D. Russell, rich red, with the guard petals slightly velvety.

Messrs. Dobbie and Co., Ltd., showed two good sorts in Marchioness of Linlithgow, rich velvety-crimson and of good form; and Duchess of Montrose, of unique form, with broad, wide opening petals, rich, glowing red in colour.

Besides those which received awards, Messrs. S. McGredy and Son had many other grand seedlings, the best of which were Patience, of grand form and rich colouring, deep orange at the base, gradually shading to orange-pink; W. E. Nickerson, pale pink, with just the slightest suggestion of salmon; Cherry Improved, a temporary name for a beautiful Rose of rich colouring and grand form; Fortitude, a grand Rose with a future before it, pure white, with a delicate tinge of flesh-pink at the tips of the enormous petals; Tom Barr, of rich and delicate colouring; Portadown Scarlet, Portadown Fragrance, rich salmon-pink shading to cerise-pink; Betty Sutor, rich rose in the centre, with reflexed, pink outer petals; Portadown Bedder, a good garden sort where colour is required; Mrs. S. Paton, of good form, with frilled petals, rose-salmon in colour; and Leslie Dudley, rich salmon-pink and shapely both in bud and when fully open.

Nurserymen's Classes.

There was only one entry in the premier competition for nurserymen, for the Jubilee Trophy, and this was by the King's Acre Nurseries, Ltd., who set up a very meritorious group, which was awarded the Cup. They had a huge central basket of Shot Silk at the back (had it been tilted slightly it would have been more effective), with grand pillars of Christine, Betty Uprichard, Golden Emblem, General McArthur and Mabel Morse. There were lovely, well-placed baskets of Madame Melanie Soupert, and Mrs. Henry Morse, while the best of the numerous other sorts displayed, in quality of the blooms, were Scarlet Glory, Lady Pirrie, Shot Silk, Covent Garden, Sunstar and Lady Inchiquin.

Mr. George Prince was deservedly placed first in the class for a group of cut Roses, twenty feet by four feet, for he put up a magnificent display of blooms in perfect condition. The background consisted of massive pillars of Dainty Bess, K. of K., American Pillar, Climbing Golden Ophelia and Climbing General McArthur, with a central basket of Mabel Morse above a mass of grand blooms of the *Daily Mail* Scented Rose, a variety which Mr. Prince has exhibited extensively this year. The corner pillars were of Betty Uprichard and Mrs. Henry Morse; there were beautiful baskets of Shot Silk, and grand vases of Angele Pernet, Colonel Oswald Fitzgerald, Lady Inchiquin, Lady Roundway, Hortulanus Budde, Elizabeth Arden and I. Zingari, with many others.

Messrs. J. Jefferies and Son, Ltd., secured second prize, their well-arranged group having central baskets of Rev. F. Page-Roberts and Mrs. Beatty, separated by a pillar of bright blooms of Lady Mary Elizabeth, at the front, while behind these was a series of pillars of grand blooms of Mrs. Herbert Stevens, Shot Silk, Hortulanus Budde, Angele Pernet, Ivy May and Emma Wright, with side baskets of Los Angeles, W. Kordes, Admiration and Lady Inchiquin.

Mr. H. Drew secured the premier award in the class for a group ten feet by four feet, his best blooms being of Betty Uprichard, Mrs. Henry Morse, White Maman Cochet, Golden Emblem and Admiration.

In the class for five baskets of cut Roses, distinct, Mr. W. Drew was first with a grand set, his varieties being Ethel Somerset, Golden Emblem, Hortulanus Budde, Ivy May and Betty Uprichard; second, Mr. H. Drew, while for three baskets, distinct, Mr. J. Mattock was awarded the first prize, for grand baskets of Shot Silk, Golden Emblem and Lady Inchiquin, the King's Acre Nurseries, Ltd., being placed second. Mr. J. Mattock was also first for twenty-four vases, distinct, his best blooms being of The Queen Alexandra Rose, Shot Silk, Doris Trayler, Ivy May and Golden Emblem; second, Messrs. J. Jefferies and Son, Ltd.

Many grand blooms were displayed in the classes for exhibition Roses in boxes. Messrs. Frank Cant and Co., Ltd., showed the best set of thirty-six, their specimens of Portadown, Augustus Hartmann, Mrs. Henry Bowles, Mrs. A. R. Barraclough, Lady Roundway and Lady Inchiquin being outstanding; second, Mr. W. Drew; third, Mr. H. Drew; while for twenty-four blooms, Mr. G. Prince was first, his best being Lord Lambourne, Lady Inchiquin and the *Daily Mail* Scented Rose.

Messrs. Frank Cant and Co., Ltd., led for twelve blooms of new Roses distributed since January 1, 1925, showing grand blooms of Portadown, Empire Queen and Aphrodite in their set; second, Mr. G. Prince, and third, Mr. W. Drew.

For two baskets of exhibition Roses, distinct, Mr. W. Drew was first, with Lady Inchiquin and Mrs. Henry Morse; the King's Acre Nurseries, Ltd., second, showing Earl Haig and Dame Edith Helen; and Messrs. Frank Cant and Co., Ltd., third, displaying Dorina Neave and Mrs. Henry Morse. Mr. J. Mattock led for one basket, with grand blooms of Mrs. Henry Morse; second, Mr. George Prince; the latter exhibitor, however, secured the premier award for one basket of a variety not yet in commerce, showing Elizabeth Arden, a grand white Rose which received a Gold Medal at the Society's show at Chelsea (see p. 38); Messrs. Bees, Ltd., were second, showing the variety Mrs. C. Aubrey.

Mrs. A. R. Bide was first for a decorated dinner table, using good blooms of I. Zingari very effectively, Mr. H. Drew secured the second prize; while Mrs. Bide was also first for a decorative bowl of cut Roses, her variety being Emma Wright; second, Mr. J. Mattock; and third, the King's Acre Nurseries, Ltd. Mr. J. Mattock was first for a decorative vase of Roses, Mrs. Bide and Mr. H. Drew being second and third, respectively.

Amateurs' Classes.

Three lovely groups were staged in the premier amateurs' class, the Jubilee Trophy being awarded to Mr. G. Marriott, Carlton, Nottingham, for a very tastefully arranged and bright display, in which the varieties Mabel Morse, Los Angeles, Doris Trayler, Ivy May, and K. of K. figured prominently. The second prize was awarded to Mr. J. E. Rayer, Worcester, who had many grand blooms, and the third to Mr. Allan Gibbs, Lisvane, Glamorgan, who showed American Pillar, Emily Gray, Mrs. Henry Morse, Francis Gaunt and Ophelia, in splendid condition.

Mr. G. Marriott also secured the premier award for two baskets of cut Roses, distinct, showing Los Angeles and Golden Emblem. Mr. J. E. Rayer was first for one basket, distinct, and Miss N. M. Bird, Hereford, led for one basket of one or more varieties, the second prize in this class going to Canon A. Claude Davies, Studley, Warwickshire.

Several good sets of blooms were staged in the classes for exhibition Roses in boxes, although in none of them was competition very keen.

Mr. J. E. Rayer showed the best twenty-four blooms, his best being of Mrs. A. Barraclough, Mildred Grant, Mabel Morse, Earl Haig, Lord Allenby and Coronation; Mrs. W. Jarrett-Thorpe, Hucclecote, Gloucester, was placed second; while the best set of twelve blooms was that staged by Mr. Allan Gibbs, who had grand blooms of Lady Inchiquin, Lady Alice Stanley, Mabel Morse and Mrs. John Laing; second, Mr. Norman Fletcher, Farringdon, Berkshire.

Mr. H. Jerrams was awarded the first prize for six blooms, while in the class for amateurs who had not previously won a first prize at a show staged by this Society, the requirements being six blooms of distinct varieties, Mr. J. G. Orpen, Carlton Road, Gloucester, was first, with good specimens of Mrs. Charles Lamplough, Mildred Grant, Marcella, George Dickson, J. G. Glassford and Mrs. G. Shawyer; Mr. H. Jerrams, was second; and Canon A. Claude Davies, third.

In the classes for amateurs who grow and stage their own Roses, Mr. J. G. Orpen was first for twelve blooms, distinct, his best varieties being Mrs. Charles Lamplough, Mrs. Foley Hobbs and Marcella; the second prize being awarded to Mr. Norman Fletcher, and the third to Mr. F. Hopcroft, Prestbury, Gloucester, both of whom had very good sets. Mr. H. Jerrams showed the best set of six blooms, these being of C. E. Shea, Mrs. Foley Hobbs, Melanie Soupert, Dean Hole, Frau Karl Druschki and Souvenir de Claude Pernet; while Canon A. Claude Davies was first for six blooms, in not less than four varieties, his best being of Admiration, Mabel Morse and Mrs. Henry Bowles; second, Mr. N. Oliver, Kingston, Herefordshire.

The Ladies' Artistic Classes were, as usual, very popular, and many charming displays were arranged. There was a large number of decorated dinner tables, the best being that attractively executed with lovely blooms of Madame Butterfly, by Mrs. Courtney Page. Miss G. M. Zelley was placed second, Miss M. M. Armitage, Hereford, third, and Miss Newsham, Aughton, near Liverpool, fourth. There was an abundance of very charming exhibits in the class for a decorative bowl of cut Roses, Mrs. Courtney Page again securing the premier award, this time with lovely blooms, charmingly arranged, of Mrs. C. E. van Rossem and Margaret McGredy; second, Miss Newsham, and third, Miss G. M. Zelley. Mrs. Courtney Page was first for a vase of cut Roses, her variety being Madame Butterfly, while in the class from which this exhibitor was excluded, namely, that for lady amateurs who had never won a first prize in the decorative section at any show held by the Society, Mrs. H. B. Dickinson, Eaton House, Hereford, staged the best decorative bowl of Roses; Mrs. Norman Fletcher securing the second prize, and Mrs. R. W. Faulkes, the third.

NATIONAL SWEET PEA.

The Provincial Exhibition of the National Sweet Pea Society was held at Eaton Park, Norwich, in conjunction with the show of the Norfolk and Norwich Horticultural Society, which was celebrating its centenary.

We have seen better and more extensive Provincial Shows, but considering the difficulties of the season, the show was a good one and fairly well filled the large tent set aside for it. A few competitors fell out at the last moment; nevertheless, the display was a bright and attractive one, and the competition quite keen in many of the classes. The arrangements were carried out well by the Secretary, Mr. A. C. Bartlett, and the numerous members of Committee present with the President, Mr. Harold Beale.

Open Classes.

The President's Prize, a piece of plate presented by Mr. Harold Beale, was won by the Hon. Arnold Henderson (gr. Mr. G. H. Starling), Writtle Park, Chelmsford, with a dozen bunches of superbly grown flowers of International, Flaming June, Idyll, Gladys, Jack Hobbs, Pinkie, Vectis, Olympia, Charming, Youth, Mrs. A. Searles and Tom Webster—a glorious set. The second prize fell to W. F. Franks, Esq. (gr. Mr. W. Humphrey), Loampits, Tunbridge Wells, who had fine vases of Royal Pink, Magnet and Glorious; third, S. Wallrock, Esq. (gr. Mr. W. H. Holloway), The Manor House, Stanmore, Middlesex; fourth, Leonard W. Butcher, Esq. (gr. Mr. W. Tizzard), Campfield Place, near Dorking; C. H. Walter, Esq. (gr. Mr. H. W. Reynolds), Drayton Old House, Norwich, Highly Commended.

Mr. Wallrock led for six bunches, distinct, with capital flowers of Mrs. A. Searles, Magnet, Youth, Powerscourt, Crusader and Valetta; second, the Hon. Arnold Henderson, who had a fine vase of Jack Hobbs; third, W. Huffey, Esq., Boormans, Yardley Place, Tonbridge; fourth, Mrs. C. Pearson (gr. Mr. C. Hodgson), Acton Place, Sudbury, Suffolk.

Mr. Wallrock was also successful in the class for three bunches, distinct, with fine blooms of Powerscourt, Mrs. A. Searles, Mrs. Arnold Hitchcock; second, Mr. W. Huffey; third, Mrs. C. Pearson; fourth, W. Martineau, Esq., The Chestnuts, Boxmoor.

In the raisers' class for six distinct varieties raised by the exhibitor, Messrs. E. W. King and Co., Coggeshall, were the only exhibitors, and well deserved the award for their set of Jack Hobbs, Vectis, Yule Log Glow (rich scarlet), Olympia, Pimpernel and Leslie Rundle.

For three vases of Sweet Peas, named seedlings, Messrs. E. W. King and Co., again led, showing Souvenir, Sonny Boy and Big Ben; Messrs. Stark and Son, second, with Leviathan, Rose Marie and Flame of Fire.

For one vase of a new seedling, Messrs. E. W. King and Co. were again successful, showing a vase of the lovely Pink Glow; the Southfield Nurseries, Netley Abbey, were second, with Michael, orange-salmon.

District Classes.

There was good competition in the Eastern Counties class for six vases, distinct, and here the Hon. Arnold Henderson led, his best flowers being of Magnet, Pinkie and Vectis; second, Mrs. C. Pearson; third, L. H. Powell, Esq. (gr. Mr. M. A. T. Pye), Inworth Hall, Kelvedon.

In the Midland Counties Class, Major H. W. Barnes (gr. Mr. E. H. Welkam), Stonecroft, Ipswich, was disqualified, on geographical grounds. The first prize was therefore awarded to Mr. J. Randall, Leamington; second, Mr. J. O. Smith, Shrewsbury.

Mr. W. F. Franks won the premier award for six vases, distinct, in the Southern Counties Class, with large, clean flowers of Powerscourt, Mammoth, Youth, Glorious, Venus and Magnet; second, Mr. S. Wallrock; third, Mr. L. W. Butcher.

Small Growers.

In the "small growers'" division, Mr. J. Randall had the best dozen bunches, distinct, and had good vases of Grenadier, Charming and What Joy; second, Mr. Claude R. Jaggs, Hertford Heath, Hertford.

The first prize for six vases was awarded to Mr. C. R. Roberts, Trunch Tee, Mundersley; he had good, long-stemmed trusses of Mammoth, Powerscourt, Mrs. A. Searles, Youth and Pinkie, but his Royal Mauve was not so good; second, Mr. C. R. Jaggs; third, Mr. J. O. Smith, Shrewsbury.

Mr. W. C. Roberts showed the best three bunches—Magnet, Powerscourt and Bluebell; second, Mr. M. K. Franks, Leatherhead; third, Colonel E. W. Skinner, Marlow, Bucks.

Among those who had not previously won a first prize at an N.S.P.S. show, Maurice K. Franks won first place for six vases, distinct, and he was well ahead of Mr. G. W. Miller, Scarning, Wareham, and Mr. J. O. Smith, who were placed second and third, respectively.

Mr. G. L. Miller led for six vases of fifteen sprays each; second, Mr. H. C. Dawes, The Durdans, Mundesley; third Mr. Charles Denny, Diss, Norfolk.

Colour Classes.

In the single bunch colour classes, Miss Russell, Canterbury, led for white, with Vectis; Major H. W. Barnes, for pink, with Magnet; Mr. W. Huffey, for lavender, with Powerscourt; Mr. S. Wallrock, for mauve, with Royal Mauve; Miss Russell, for cream, with Ivory Picture, and for orange, with Royal Sovereign; Mr. W. F. Franks, for crimson, with Honour; Miss Russell, for scarlet or orange-scarlet, with Flaming June; Miss Russell, for maroon, with Warrior; Mr. W. Huffey, for Picotee-edged, with Youth; and Mr. W. Franks, for blue, with Gleneagles.

Decorative Classes.

Mrs. C. H. Rundle, Barton Court Gardens, Canterbury, led for a bowl of Sweet Peas, with an arrangement of salmon, cream and mauve flowers; second, Miss Gladys Burt; third, Miss Mavis Burt.

The best vase of Sweet Peas was shown by Mrs. C. H. Rundle, who had mauve and pink flowers; second, Miss Mavis Burt; third, Miss Gladys Burt.

Scarlet and pale mauve flowers were used by Miss H. Cross, Arminghall, Norwich, in her first prize table collection of Sweet Peas; second, Mrs. H. Harrowven, Old Catton; third, Mrs. W. Lee Spink, North Dene, Great Yarmouth.

Trade Displays

Messrs. Sutton and Sons were awarded a Gold Medal for a large group of bouquets of Sweet Peas, arranged at varying heights, at one end of the tent. Their leading sorts were Idyll, Powerscourt, Colorado, Pinkie, Mammoth and Royal Mauve.

Messrs. E. W. King and Co. received a Gold Medal for a group of fine blooms arranged in bowls; leading varieties were Big Ben (Award of Merit, 1929), Jack Hobbs, Gladys, Leslie Rundle, Souvenir, Guardsman, Pimpernel, Yule Log Glow and Huntsman.

Mr. R. F. M. Wiltshire, Southfield Nurseries, Netley Abbey, was awarded a Silver-gilt Medal and Messrs. Stark and Son, Great Ryburgh, a Silver Medal, for groups of Sweet Peas.

Messrs. James Carter and Co., Raynes Park, showed large bunches of good blooms of Flaming June (Gold Medal, 1928-9), Sweet Seventeen and Porcelain.

READING GARDENERS'.

The first evening meeting of the summer session was held by the kind permission of Messrs. Sutton and Sons at their Trial Grounds, London Road, Reading, in late June, when there was a record attendance of about one hundred and fifty members, including the President, Mr. Frank E. Moring, the Chairman, Mr. W. Broomfield, and the Vice-Chairman, Mr. E. Blackwell.

After inspecting the large collection of Sweet Peas grown for exhibition purposes, the party proceeded to the very interesting trials of Lettuce and culinary Peas. Special interest was taken in the Vegetables growing for exhibition, especially noticeable being the large pods of Sutton's V.C. Pea. On the way to the glasshouses splendid batches of Sweet Williams, Delphiniums, Canterbury Bells and Phacelia campanulata were noted.

In the houses the Begonias and Streptocarpuses were exceedingly fine, while the seedling Gloxinias, although not in flower, gave promise of a beautiful display in the near future.

The opportunity was taken to hold a Sweet Pea Competition and three classes were arranged. In Class 1 (open), for three vases of three distinct varieties, twelve sprays to a vase, there were four entries and the first prize, which included the National Sweet Pea Society's Silver Medal, was gained by Mr. A. W. Gower, Calcot Grange Gardens, with splendid blooms of Pinkie, Constance Hinton and Mrs. A. Searles. The second went to Mr. Tuffin, Iris Court Gardens, Pangbourne, and the third to Mr. A. H. Dow, Suthampstead House Gardens.

In Class 2 (open), for one vase, mixed colours, of eighteen sprays, there were three entries and the prizes were awarded as follow:—First, Mr. R. G. Taylor, Highgrove Street, Reading; second, Mr. H. Reeves, Broadfield, Northcourt Avenue, Reading, and the third, Mr. A. Dow, Junr., Suthampstead.

In Class 3, for single-handed gardeners only, for one vase mixed colours, eighteen sprays to a vase, there was keen competition. Mr. F. Haines, Calcot Hanger Gardens, was first; Mr. A. Terry, Hawthorn Cottage, Earley, second; and Mr. H. Oliver, Earley Road, Reading, third.

Before the party separated, the President, on behalf of the members, tendered to Messrs. Sutton and Sons a hearty vote of thanks for enabling them to spend such an interesting and enjoyable evening. A similar vote was extended to the members of the staff who had so kindly interested themselves in the visit.

A party of between sixty and seventy members of the Reading and District Gardeners' Association recently visited the Lodden Nurseries, Twyford, by kind permission of Mr. H. Carlile, who met the party on arrival and conducted it to the Delphiniums, which are grown in thousands. The chief characteristics of the different varieties were pointed out, and although space will not permit mention of all the excellent varieties seen, the following certainly stood out most prominently, viz., Triumph, Norah Ferguson, Mrs. Carlile, Fair Lady, Blue Bird

Blue Queen, Dorothy Richardson, Lodden Guard, Lord Derby, George Cochrane, Lady Prince and Gloriosa, while the collection of new varieties not yet in commerce included such beautiful types as Eve, Lord of Lodden and June.

Leaving the Delphiniums, the members proceeded to the Gaillardias, Scabious caucasica, Linums, Helianthemums, and a host of beautiful subjects suitable for the rockery.

After partaking of refreshments kindly provided by Mr. Carlile, another treat was in store, for he had arranged for motor-coaches to convey the party to his Chalk Hill Nurseries, Reading, where about one hundred varieties of Delphiniums are grown for exhibition purposes. Needless to state, these were in the pink of condition and called forth much admiration. Before separating, Mr. Broomfield (Chairman) voiced the thanks of the members to Mr. Carlile for the interesting evening and his hospitality.

NORFOLK AND NORWICH HORTICULTURAL.

In the spacious Eaton Park, Norwich, the Norfolk and Norwich Horticultural Society held its Centenary Exhibition on July 11 and 12. Four large tents were used, and these were arranged in opposite pairs, with plenty of space between them. An interesting coincidence was that the present President, Major E. H. Evans Lombe, of Marlingford Hall, Norwich, had an ancestor who was the first President of the Society, a century ago, indeed, Edward Lombe was President in 1829, 1830 and 1831.

The exhibition was a good one, although owing to the untoward season, it failed to reach the high standard of excellence anticipated by the Society, for in Norfolk, as elsewhere, gardeners are largely in the hands of the clerk of the weather. To celebrate the occasion, the National Sweet Pea Society held its Provincial Show at Eaton Park, the National Rose Society sent a deputation, and to crown all, a deputation of the Council of the Royal Horticultural Society went and made special R.H.S. awards to deserving exhibits. This deputation consisted of Mr. E. A. Bowles, Mr. Thomas Hay, Mr. W. Cuthbertson, Mr. G. W. Leak, and Mr. A. Simmonds, the Assistant Secretary of the R.H.S.

The weather was propitious; indeed, the opening day was one of the most summer-like yet experienced. The attendance was good, notwithstanding the long distance from the centre of the city to Eaton Park.

The President, Vice-President and Committee of the Norfolk and Norwich Society entertained their visitors to luncheon, and following the lunch, we heard a series of the most entertaining speeches we have heard, at one sitting, for a very long time. Evidently the air of Norwich is conducive to witty oratory.

Roses.

In the open classes, Messrs. Frank Cant and Co. were highly successful, winning first prizes for thirty-six blooms, distinct, with Coronation and Mabel Morse, in fine form; for six distinct varieties, three blooms of each, with Mrs. Charles Lamplough, Mabel Morse and Mrs. H. Morse, conspicuously good; for a dozen distinct varieties; and twelve blooms in not fewer than eight new sorts.

Messrs. H. Morse and Sons, Eaton, led for three baskets of cut Roses, the varieties exhibited being Golden Emblem, Portadown and Lady Beatty; second, Messrs. A. J. and C. Allen. The best eighteen decorative Roses were from Mr. E. Le Grice, Roseland, near Walsham.

For an arrangement of Roses on a space six feet by two-and-a-half feet, the first prize was won by Mr. E. Le Grice, whose pillars of Desmond Johnston and basket of Betty Uprichard were particularly effective; second, Mr. E. W. Parkin, Swardeston.

In the amateurs' division, Dr. E Deacon (gr. Mr. Baldwin) won first prize with a fine lot of flowers in the class for eighteen blooms, distinct. Dr. Deacon was also successful in the class for six varieties of Roses, three of each, and his set included a very fine example of Mrs. Barraclough. Mrs. Campbell Steward, Sarlingham, led for a dozen blooms, distinct, and Mr. Henry Johnson was placed first for six distinct varieties, and included Paul's Lemon Pillar in good form.

In the small growers' classes, E. C. Shaw, Esq. (gr. Mr. M. A. West), Carlton Colville, won the premier award for twelve blooms, and showed Mabel Morse, Admiration and Rev. F. Page Roberts in fine form; second, Rev. A. Garry Copeman (gr. Mr. W. H. Wilson), Thorpehurst, Thorpe. In the same section, Mr. F. Harrison, Old Catton, and Mrs. Johnson, were also prize-winners.

In the Norfolk County Classes the premier award for a group of Roses arranged on a space five feet by two-and-a-half feet, was won by R. G. Coller, Esq. (gr. Mr. H. Spurgeon), Wroxham, with a quaintly designed display of pleasing flowers—a sort of cairn of Rose blooms. Mrs. Campbell Steward led for six blooms and in another class for six flowers, Mr. J. C. Porter secured the first prize.

Sweet Peas.

The G. E. White Challenge Cup, offered for the best twenty-four bunches of Sweet Peas, was won by Mrs. A. E. Lark (gr. Mr. Langrove), Holland Hall, who also won the N.S.P.S. Medal for the best bunch in the show, with Corona; the Mundesley Sanatorium (gr. Mr. Gotts), came second. Dr. E. Deacon (gr. Mr. Baldwin), Brundall, scored for twelve bunches of Sweet Peas, followed by J. Pearson, Esq. (gr. Mr. C. E. Cooper), Boston.

W. W. Poll, Esq. (gr. Mr. J. Alborough), Hethersett, had the best six bunches of Sweet Peas, showing good flowers of Pinkie, Sunkist, Charming, Sybil Henshaw, Mrs. A. Searles and Mrs. Horace Wright; second, Dr. A. Davidson (gr. Mr. Rainbow), Thorpe.

In the colour classes, Dr. Deacon led for lavender with International, and crimson, with Charity. Mr. W. W. Poll led for scarlet or orange, with Huntsman, and the Mundesley Sanatorium scored for the best bunch of a variety introduced since 1926, with Mrs. Jack Hobbs.

Major A. L. Brown (gr. Mr. W. C. Dean), Brooke Hall; Mr. W. W. Poll; Mrs. D. H. Lane (gr. Mr. T. Parker); and Mr. G. L. Miller were other prize-winners in Sweet Pea classes.

Hardy Flowers.

The best amateur's collection of cut flowers and, or, plants, displayed on a space eighteen feet by six feet, was arranged by H. W. Empson, Esq., Cross Ways, North Walsham, who had an imposing exhibit of Astilbes, Delphiniums, Acanthus, Heucheras, Primulas, Irises, Paeonies and Campanulas.

The Silver Challenge Cup for two dozen bunches of hardy flowers was won by the Norwich Corporation (gr. Mr. Starland), with a bright collection that included Delphiniums, Potentillas, Gaillardias. Erigerons, etc.; second, Mr. E. H. Bond. J. M. Taylor, Esq. (gr. Mr. H. Balls), Oulton Broad, led for a dozen bunches of hardy flowers, and showed fine bunches of Achillea, Erigerons, Galega and a Salvia S. felix; the competition was good in this and many other classes for hardy flowers.

An interesting class was the one for six kinds of hardy flowering shrubs, J. C. Christie winning with Olearia macrodonta, Carpentaria californica, Philadelphus purpureo-maculatus, Buddleia Colvillei and Magnolia parviflora in good condition; second, the Norwich Corporation, who included Solanum crispum and Escallonia langleyensis in their set.

Delphiniums made a brave show, and Mr. G. L. Lang led for six varieties with Blue Bird, Rev. Lascelles, Nellie, Dusky Monarch, etc., and was awarded the Veitch Memorial Medal for his exhibit; second, Mr. A. Davidson, Thorpe.

Sweet Williams were uncommonly well shown by Mr. G. L. Lang, and others, while J. A. Christie, Esq., led for three vases of Lilies with L. Hansonii, L. Martagon and L. Henryi, and was also first for one vase of Lilies, with L. Henryi.

Floral Designs.

Mrs. Sandys Winch, Brundall, had the best bowl of Sweet Peas and also the best vase of flowers, winning in the latter class with Scabious. The same lady led in the class for a table decoration of Roses, showing Irish Elegance; Miss H. Cross, second, and Mrs. Empson, third. Mrs. E. L. Miller had the best basket of Sweet Peas.

Mrs. Sandys Winch was also the chief prize-winner in the classes for a basket or bowl of Roses and for a vase of Roses. Mrs. Sandys Winch was again successful in the class for a table decoration of any other flowers than Roses, using white, mauve and pink Sweet Peas; second, Mrs. Empson, with a miniature rock garden design.

Fruits and Vegetables.

Major A. Le Bruce had his own way in the leading classes for fruits, winning for six dishes with Cardinal Nectarines, Alexander Peaches, Buckland Sweetwater and Black Hamburgh Grapes, Cherries, and Brown Turkey Figs; for black Grapes, for white Grapes, and for a single bunch of Grapes.

Mr. W. C. Crawshay had the best green-fleshed Melon; Major A. Le Bruce the best Peaches — Alexander; and the Mundesley Sanatorium the best set of four dishes of Strawberries, showing excellent fruits of Sir Joseph Paxton, Royal Sovereign, Givon's Late Prolific and Bedfordshire Champion. J. A. Christie, Esq. (gr. Mr. High), Framlingham Manor, had the best dish of Figs.

The best collection of eight kinds of vegetables was shown by the Mundesley Sanatorium with good examples of Potatos, Onions, Cauliflowers, dwarf Beans, Peas, Tomatos, Carrots and Cucumbers; second, G. L. Lang, Esq. (gr. Mr. F. Sheldrake), Great Plumstead Hall; third, Major A. Le Bruce (gr. Mr. Dean), Brooke Hall.

Trade Displays.

Non-competitive exhibits were numerous and good. Messrs. Dobbie and Co. exhibited a splendid group of well-grown Sweet Peas in popular varieties, and it received well-deserved commendation. Messrs. Daniels Bros. contributed groups of hardy flowers, of Hydrangeas and of Vegetables. Messrs. A. Reeves and Co., Oulton, had a good display of Roses, and secured three Medals—local, R.H.S. and N.R.S. Messrs. H. Morse and Son and Messrs. Allen also contributed excellent groups of Roses. Messrs. Lowe and Gibson showed Delphiniums, and Messrs. R. H. Bath exhibited a big group of Delphiniums, Paeonies, etc. Messrs. Isaac House and Son contributed Scabious, and Messrs. Hewitt sent Delphiniums. Messrs. Stark and Son had a very fine exhibit of Poppies of the Coonara, Ryburgh and other strains. Messrs. John Peed and Son exhibited a large and bright group of Hydrangeas, well-grown Codiaeums, Dracaenas, Caladiums and Gloxinias.

Royal Horticultural Society's Awards.

The deputation from the Royal Horticultural Society made the following awards :—

Gold Medals.—To Messrs. A. J. and C. Allen, for Roses; and to Messrs. Dobbie and Co., for Sweet Peas.

Silver-Gilt Flora Medals.—To Messrs. R. H. Bath, Ltd., for Delphiniums and other herbaceous plants; Messrs. Daniels Brothers, for a mixed group of Gladioli, Roses, and Sweet Peas; and to Messrs. A. Reeves and Co., for Roses.

Silver-gilt Banksian Medals.—To Messrs. Hewitt, for Delphiniums; and to Messrs. J. Peed and Son, for stove and greenhouse plants.

Silver Flora Medals.—To the Hon. Arnold Henderson, Writtle Park, Chelmsford (gr. Mr. E. H. Starling), for Sweet Peas; and to Messrs. Stark and Son, Fakenham, Norfolk, for Poppies and other hardy flowers.

Silver Banksian Medals.—To J. A. Christie, Esq., M.P. (gr. Mr. Sam High), The Manor House, Framlingham Pigot, for hardy shrubs; Baroness Cederstrom, Hoveringland Hall (gr. Mr. F. Tweed), for annuals and biennials; Samuel Wallrock, Esq., (gr. Mr. W. H. Holloway), The Manor House, Stanmore for Sweet Peas; Mr. G. W. Miller, for a mixed group of herbaceous plants and Roses; Messrs. Isaac House and Son, for Scabious and other herbaceous plants; and to Messrs. Lowe and Gibson, Ltd., for Delphiniums and border Carnations.

Silver Veitch Memorial Medal and £5.—To G. L. Lang, Esq. (gr. Mr. F. Sheldrake), Great Plumstead Hall, for Delphiniums.

Bronze Veitch Memorial Medal and £2 10s. 0d. —To Gordon Winter, Esq., Wramplingham, for seedling Pinks.

ROYAL HORTICULTURAL.

July 16.—There was quite an interesting variety of events in association with this fortnightly meeting of the R.H.S. in the new Horticultural Hall, Westminster, on this date. In addition to the customary show of flowers in season there was the Rose competition for the Clay Cup, a culinary Pea competition, the National Farmers' Union Cherry Show, and the annual show of the London and South of England Viola and Pansy Society. Owing to pressure on our space, the reports of the two last-named shows are reserved for our next issue. Orchids were fewer than of late, and the Committee recommended only one Award of Merit to a novelty. Roses and Delphiniums were the chief floral features and these, as well as general border flowers were admirably shown. The Floral Committee recommended five Awards of Merit to novelties, and selected four Delphiniums and an Eschscholzia for Trial at Wisley. Although there was no novelty of moment before the Fruit and Vegetable Committee, there were several exceedingly interesting exhibits in the hall.

Orchid Committee.

Present: Sir Jeremiah Colman (in the chair), Mr. Frederick J. Hanbury, Mr. Gurney Wilson (Hon. Secretary), Mr. E. R. Ashton, Mr. John Cowan, Mr. T. Armstrong, Mr. J. E, Shill, Mr. Fred K. Sander, and Mr. Arthur Dye.

Award of Merit.

Odontonia Vesta.—A hybrid of uncommon marking, derived from Odontonia Dora × Miltonia William Pitt. The sepals are heavily marked with purple and a few dull chocolate spots and margined with white. The frontal portion has heavy chocolate markings on a white ground. Shown by Messrs. Charlesworth and Co.

Botanical Certificate.

Cymbidium atropurpureum.—A well-grown plant bearing a long, drooping spike of twenty-five flowers was shown. The flowers were of medium size with deep, shining, chocolate sepals, and a pale yellow lip spotted with chocolate. Shown by Messrs. Sander.

Cultural Commendation.

Vanda Batemannii.—An exceptionally well-grown specimen was shown by Messrs. Sander.

Groups.

There were only two small collections of Orchids in the hall. Messrs. Sander gave the central place to their specimen of Vanda Batemanni, and also placed Cymbidium atropurpureum, Phalaenopsis Rimstadianum, Laelio-Cattleya Isabel Sander, Coelogyne Mooreana and Lycaste leucantha in prominent positions.

The chief plants staged by Messrs. Charlesworth and Co. were Laelio-Cattleya Colmaniana, Sophro-Laelio-Cattleya Adonis, Brasso-Cattleya Irene and Rodriguezia secunda.

Floral Committee.

Present: Section A.—Mr. Henry B. May (in the chair), Mr. Arthur Turner, Mrs. Ethel M. Wightman, Mr. D. B. Crane, Mr. D. Ingamells, Mr. Charles E. Pearson, Mr. George Churcher, Mr. W. B. Gingell, Mr. M. C. Allwood, Mr. A. E. Vasey, Mr. James B. Riding, Mr. Courtney Page, Mr. E. R. Janes, Mr. William Howe, and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. Charles T. Musgrave (in the chair), Sir William Lawrence, Bt., Mr. A. Williams, Mr. L. R. Russell, Mr. Mark Fenwick, Lady Beatrix Stanley, Mr. R. C. Notcutt, Mr. Amos Perry, Mr. A. Bedford, Mr. E. A. Bowles, Mr. T. Hay, Mr. T. W. Taylor, the Hon. Henry D. McLaren the Marquess of Hartington, Mr. W. Irving, and Mr. N. K. Gould, Secretary.

Awards of Merit.

Anthemis tinctoria, Perry's var.—This is a very desirable and distinctly improved variety of the well-known Yellow Camomile. Shown by Mr. Amos Perry.

Carnation Beauty of Cambridge.—A very fine and fragrant, deep primrose-yellow border variety. Shown by Messrs. R. H. Bath, Ltd.

Gentiana hexaphylla.—A pretty, dwarf, blue Gentian from north-west Yunnan. It bears relatively large, solitary, medium-blue flowers, which have primrose markings, on stiff, purplish stems, clothed with whorls of short, narrowly-lanceolate leaves with rounded apices. Shown by Andrew Harley, Esq. (gr. Mr. T. Doig), Devon Hall, Dollar, Perth.

Philadelphus insignis.—An exceedingly good single-flowered Philadelphus. It is of vigorous habit, very floriferous, and the clean white flowers are deliciously fragrant. Shown by Charles T. Musgrave, Esq., Hascombe Place, Godalming.

Verbena sp., C.E. 354.—The award to this pretty herbaceous plant from Chili is subject to it being named correctly. It is about two feet in height. The stems are square and bear opposite, ovate-lanceolate, serrate leaves of harsh texture. The small, deep lavender flowers are borne in dense heads. Shown by Mr. Clarence Elliott.

For Trial at Wisley.

Delphinium Gladys Thrale.—A good spike of rounded, blue and purple flowers. This and a similar seedling, but with a whiter eye, was shown by W. H. Grant, Esq., Croydon.

D. Hewitt's Superb.—A handsome, compact spike of lavender and Cambridge-blue flowers. Shown by Messrs. Hewitt, Ltd.

D. Eileen May Robinson —A loose spike of long-stemmed lavender and sky-blue flowers. Shown by Mr. Herbert Robinson.

Eschscholzia Eastern Queen.—A very showy variety. The outsides of the large flowers are shining cardinal, and the interiors are pale buff. Shown by D. H. Gardiner, Esq., Thornington, Colchester.

The Clay Cup for Fragrant Roses.

There were fourteen good H.T. Roses set up in a competition for the Clay Cup, which was awarded to the variety Aroma, shown by Messrs. B. R. Cant and Sons. It is a deliciously fragrant, deep rose-pink to light crimson flower of globular shape. Messrs. Dobbie and Co. showed a very fragrant, crimson Rose but, unfortunately, it was not accompanied by a plant as required by the conditions of the competition. Barbara Richards, was the best-formed Rose, and it also possessed agreeable fragrance.

Groups.

Roses of exceedingly good quality were shown extensively, and although the H.T. varieties predominated, there were good vases and stands of the climbing and rambling Roses. The chief exhibitors were Messrs. S. McGredy and Son, Mr. H. J. Pemberton, Messrs. Frank Cant and Co., Messrs. B. R. Cant and Son, Messrs. Alex. Dickson and Sons, Messrs. Ben. Cant and Co., Messrs. Wilson and Agar, Messrs. W. E. Archer and Daughter, Mr. E. B. Le Grice and Messrs. Bunyard and Co., who had an exceedingly interesting collection of old-fashioned Roses.

Carnations were staged in the accustomed good quality by Messrs. C. Engelmann, Ltd., and Messrs. Allwood Bros. The latter also showed many pretty varieties of Dianthus Allwoodii, and a bed of Dianthus "Sweet Wivelsfield."

Delphiniums of superb quality filled almost the whole of the wall space, and there was a splendid circular group arranged by Messrs. Blackmore and Langdon in the middle of the hall. Their chief varieties were Sir Douglas Haig, Cambria, The Shah, Lord Derby and F. W. Smith.

In a delightful collection of magnificent Delphinium spikes, Messrs. H. J. Jones included such splendid varieties of pale heliotrope and sky-blue colouring as Mrs. Stilwell, Ryecroft, Millicent Blackburn, Mrs. W. R. Dykes and Miss Lettie Fairfax, and also W. Heaton, of pure sky-blue colour. The dark blue varieties were prominent in the good collection of Mr. T. Bones, and these included Hunsdon Dell, Clarissa, Dina and Orion. Mr. T. Carlile had several good dark heliotrope coloured sorts, of which George Cochrane, Lord Derby and Coquette are a selection. The dark blue varieties shown by Messrs. Hewitt, Ltd., included The Bishop, King Bladud, Violet Queen and Rose Marie.

A large and interesting collection of seasonable border flowers was arranged by Messrs. B. Ladhams, Ltd., who also showed garden Pinks and a model, formal water garden replete with Nymphaeas and other aquatics. Messrs. Patricks had a good group of hardy shrubs.

On the staging, Messrs. Barr and Sons grouped many desirable border flowers, such as Delphiniums, Liliums in variety, and herbaceous Phloxes. Mr. George E. P. Wood, Messrs. Tuckers, Ltd., Messrs. Maxwell and Beale, the Misses Hopkins, Messrs. G. and A. Clark, Mr. A. Miles and the Little Munden Nurseries had collections of seasonable flowers, and Mr. Amos Perry set up a large group of his new variety of Anthemis tinctoria.

A graceful group of Eremurus Bungei and Eremurus Shelford was arranged by Messrs. W. Artindale and Son. Mr. James Douglas staged a fine collection of border Carnations, which included Red Hussar, King of Scarlets and Flambeau.

The end of the hall was filled by Messrs. Dobbie and Co. with a magnificent collection of Sweet Peas. Their many varieties included Gleneagles, Mrs. A. Searles, Magnet, Sunkist, Youth and Idyl. Close by, they had a pretty group of Lilium regale, and Messrs. Waterer, Sons and Crisp showed Japanese Irises and Astilbes. Messrs. M. Prichard and Sons, had a very complete collection of Astilbes with Japanese Irises.

An exceptionally complete collection of foliage Begonias was staged by Messrs. L. R. Russell, Ltd. The varieties of Begonia Rex were most prominent, and these included Marechal Foch, La Marquise, Charles Louriden, Perle de Mortefontaine and Vesuve, while there were many others of value.

Fruit and Vegetable Committee.

Present: Mr. E. A. Bunyard (in the chair), Mr. C. G. A. Nix, Mr. H. S. Rivers, Mr. H. V. Taylor, Mr. J. Wilson, Mr. P. A. Tuckett, Mr. Edwin Beckett, Mr. George F. Tinley and Mr. W. F. Giles, and Mr. A. N. Rawes, Secretary.

Culinary Pea Competition.

On the occasion of this meeting of the Society, a competition for culinary Peas was held, but it was not a success. There were only two exhibitors in Class 1, for six dishes, distinct, Samuel Wallrock, Esq. (gr. Mr. W. H. Holloway), The Manor House, Stanmore, Middlesex, was placed first, with grand dishes of Duke of Albany, V.C., Admiral Beatty, Quite Content, Early Giant and Daffodil. H. W. Henderson, Esq. (gr. Mr. F. L. Pike), Woodhay, Newbury, Berkshire, had good pods of Bedfordshire Champion, Gradus, Pioneer, Admiral Beatty, Roupell Masterpiece and Alderman, in his second prize exhibit.

In Class 2, for three dishes, R. Chetwynd-

Stapylton (gr. Mr. W. Meager), Headlands, Berkhamsted, was the only exhibitor, and he was awarded the first prize, his varieties being Gradus, Duke of Albany and Quite Content.

Groups.

Messrs. G. Bunyard and Co., Ltd., staged a magnificent representative collection of Cherries, embracing quite sixty varieties, including many Continental sorts.

A collection of choice fruits, embracing Tomatos and Cucumbers, Gooseberries, Melons, Grapes and Raspberries, was staged by the Swanley Horticultural College; while British Glasshouse Produce Marketing Association, Ltd., had a grand exhibit of fruits, including Peaches, Grapes, Tomatos and Cucumbers, beautifully graded and packed as for market.

The East Malling Research Station was responsible for a very educational exhibit, arranged in four sections. The first was of various Raspberries, punnets of fruits and vases of typical growths of each variety being displayed. The next was an exhibit demonstrating the classification of Black Currants, with information on the characters by which the varieties may be identified, and fruiting growths and punnets of fruits of the varieties Goliath, French, Boskoop Giant and Baldwin. There were fruiting growths and punnets of fruits of the chief commercial varieties of Red Currants, together with information regarding the classification of these fruits; while the fourth section was a demonstration of bacterial canker or die-back of Cherries.

Grand fruiting sprays of Black Currant Seabrook's Black and Raspberry Lloyd George, were shown by Messrs. W. Seabrook and Sons.

Messrs. Sutton and Sons and Messrs. James Carter and Co. staged grand collections of culinary Peas, in great variety and splendid condition; both were highly educational.

GENERAL BULB GROWERS' OF HAARLEM (HOLLAND).

The following awards were made by the Narcissus Committee of the above Society during the spring meetings of 1929.

First Class Certificates.

Narcissus Daphne (*double Poeticus*).—Pure white. Raised by Mr. F. Culpin.

Narcissus Irene Copeland (*double*).—White and soft yellow. Raised by Mr. W. F. M. Copeland.

Tulip Gadelan (*Parrot*).—Purple and violet.

Awards of Merit (Market Flowers).

Narcissus Henna (*Incomparabilis*).—Deep lemon-yellow perianth, with a clear orange, tubular cup. Raised by Mrs. R. O. Backhouse.

Narcissus Red Rim (*Poeticus*).—Round, white perianth; the flattened, greenish-yellow cup has a wide, orange-red edge. Raised by the Rev. G. H. Engleheart.

Narcissus Wide Wing (*Poeticus*).—White perianth and yellow cup edged with red. Raised by the Rev. G. H. Engleheart.

Awards of Merit (Show Flowers.)

Narcissus American Beauty (*yellow Trumpet*).—Regular, overlapping, clear yellow perianth segments, with a frilled trumpet of somewhat darker shade. Raised by Messrs. J. Gerritsen and Sons, at Voorschoten.

Narcissus Boston.—Sulphur-white perianth, with a yellow, orange-edged cup, two to four flowers being borne on one stem. Raised by Messrs. A. Frylink and Sons, at Sassenheim.

Narcissus Commander Byrd (*bicolor Trumpet*).—Sulphur-white perianth with a large, heavily frilled, lemon-yellow trumpet. Raised by Messrs. van Zonneveld Bros. and Philippo, at Sassenheim.

Narcissus Cymric Queen (*Incomparabilis*).—A large flower, with overlapping, milky-white perianth segments; cup clear yellow, with a broad, orange margin. Raised by Messrs. de Graaff.

Narcissus Dactyl (*Poeticus*).—White, flat perianth, and a yellow, red-edged cup. Raised by the Rev. G. H. Engleheart.

Narcissus Estelle (*Incomparabilis*).—Lemon-yellow perianth, with a heavily frilled, deep orange cup. Raised by Mrs. R. O. Backhouse.

Narcissus Excelsior (*Poetaz*).—Milky-white perianth, with an orange-yellow cup.

Narcissus Feu de Joie (*double Incomparabilis*).—Sulphur-yellow and deep orange. Raised by Mr. W. F. M. Copeland.

Narcissus Friar (*Leedsii*).—Sulphur-white perianth, and a small, frilled, yellow cup. Raised by Mrs. R. O. Backhouse.

Narcissus Glory of Oegstgeest (*yellow Trumpet*).—A flower of medium size, with a broad, yellow, heavily-frilled trumpet. Raised by Messrs. G. Lubbe and Son, at Oegstgeest.

Narcissus Helen Wills (*Incomparabilis*).—Creamy-white perianth, and a trumpet-shaped, orange cup. Raised by Messrs. E. H. Krelage and Son, at Haarlem.

Narcissus Innes (*Incomparabilis*).—Sulphur-yellow, undulated perianth and broad, frilled cup.

Narcissus Irmelin (*Poetaz*).—Sulphur-white perianth, and a clear orange cup.

Narcissus J. K. Ramsbottom (*Barrii*).—Clear white perianth, and deep yellow, orange-edged cup. Raised by Mr. P. D. Williams.

Narcissus Marvellous (*bicolor Trumpet*).—A very large flower, with sulphur-white perianth segments and a large, golden-yellow trumpet. Raised by Messrs. C. Alkemade Azn.

Narcissus Mongolia (*yellow Trumpet*).—Pure yellow, with deep yellow, orange-shaded trumpet. Raised by Messrs. C. G. van Tubergen, at Haarlem.

Narcissus Mr. Nijgh (*Barrii*).—Clear white perianth, and a frilled, deep orange cup with a yellow centre. Raised by Mrs. R. O. Backhouse.

Narcissus Naomi (*Barrii*).—Flat, sulphur-yellow perianth and a butter-yellow cup with deep orange edge. Raised by Mrs. R. O. Backhouse.

Narcissus Orange Circlet (*Incomparabilis*).—Perianth lemon-yellow; cup butter-yellow, with a distinct, orange-red edge. Raised by Messrs. Barr and Sons, at London.

Narcissus Peerless (*Poetaz*).—Soft apricot, with deep orange cup. Raised by Mrs. R. O. Backhouse.

Narcissus Polwijn (*Poeticus*).—Clear white with flat, yellow cup edged with red. Raised by Mr. P. D. Williams.

Narcissus Red Knight (*Incomparabilis*).—Perianth creamy-white, and a large, clear orange cup. Raised by Mrs. R. O. Backhouse.

Narcissus Roman Star (*Barrii*).—Creamy-white perianth, and broad, deep-orange, strongly frilled, flattened cup. Raised by Messrs. de Graaff Bros.

Narcissus Royalty (*yellow Trumpet*).—Primrose-yellow, with stout, wide-opened, lemon-yellow trumpet. Raised by Messrs. C. G. van Tubergen, at Haarlem.

Narcissus Rust-hof (*Barrii*).—Round, overlapping, pure-white perianth segments and flat, yellow, orange-edged cup.

Narcissus Searchlight (*yellow Trumpet*).—Golden-yellow perianth and a wide-opened trumpet, with a slightly frilled border.

Narcissus Statendum (*yellow Trumpet*).—Clear golden-yellow. Raised by Messrs. de Graaff Bros.

Narcissus Sylphide (*bicolor Trumpet*).—Snow-white perianth, and soft, canary-yellow, wide opened trumpet.

Narcissus Twinkle (*Barrii*).—A small flower, apricot, with a deep orange cup and apricot-coloured stamina. Raised by Mrs. R. O. Backhouse.

Narcissus Vixen (*Incomparabilis*).—Sulphur-white perianth, and a wide-opened, clear orange cup. Raised by Mrs. R. O. Backhouse.

Narcissus White Giant (*Poetaz*).—Creamy-white perianth and broad, orange cup.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

The monthly meeting of this Society was held in the R.H.S. Hall on Monday, July 8, Mr. Charles H. Curtis presiding. Eight new members were elected. Two members withdrew the sum of £52 10s. 11d. from their deposit accounts, and the sum of £104 14s. 11d. was passed for payment to the nominees of two deceased members. The sick pay for the month on the private side came to £89 19s. 0d., and in the State Section to £72 0s. 6d., while Maternity Benefits totalled £11 10s. 0d. The sum of £29 10s. 4d. was granted to eight members on the State Section for dental and optical treatment, and five other cases were considered.

BRITISH CARNATION.

The following new Carnations have been registered with the British Carnation Society:—

W. H. Wallace.—Seedling. Colour deep salmon-pink; raised by the late Mr. W. H. Wallace and registered by Mr. W. E. Wallace, Eaton Bray, Dunstable.

Catthorpe Cherry Red.—Sport from Baroness de Brienen; colour bright cherry-red; large, fragrant flowers; habit of growth and stem as parent. Raised by Mr. W. G. Donce, Catthorpe Manor Gardens, Rugby.

At a Council meeting held on June 25, the Chairman presented the late Secretary, Mr. Percy F. Bunyard, with the Society's Gold Medal as a token of appreciation for valuable services to the Society.

Mr. J. D. Simpson, Ashton-on-Ribble, kindly offered to present two Gold Medals to the gardeners who show the best vases of five blooms at the Society's 1930 shows, and Mr. R. F. Felton offered two Silver-gilt Medals as second prizes in the same classes.

MORAY FIELD CLUB.

The Moray Field Club, which on this occasion was joined by the Elgin and Moray Literary and Scientific Association, held its June excursion to Aberlour Orphanage, the leading orphanage in Scotland belonging to the Scottish Episcopal Church. After a minute inspection of the buildings, with its happy 450 girls and boys, under the guidance of the warden, the Rev. Clarence A. E. Wolfe, B.A., the party was taken round the gardens by Mr. White, M.A., who is well-known in Scottish horticultural circles.

The Tomato houses were visited first and some fine work was seen here. In a space 35 feet by 10 feet, a little over half of which is occupied by Tomatos, over 600 lbs. of Tomatos were grown last year, and the prospects this year are even better. The best variety is known as No. 8, a product of two well-known strains, a peculiarity of which is that the joints between the clusters are shorter and so take up less space. The Begonia house, however, was the chief source of delight to the visitors. Here they found that wonderful scented variety which Mr. White has the great honour of raising, the only other known person working on the culture of scented varieties being Mons. Le Maine, Nancy, France. But the latter's productions are diminutive compared with the magnificent double, orange-yellow blooms at Aberlour. Mr. White was the first to produce a double, scented Begonia. It is a cross between a small-flowered, scented Begonia, a native of Bolivia, and a single pink Begonia, also with rather small blooms. The scent is detected only in the morning and early forenoon, when it fades away to return again in the evening. An outstanding feature in this house was a superb double pink Begonia measuring over seven inches in diameter and perfect in form. Mr. White declared that in all his experience it was the finest he had ever grown. Unfortunately the weather was far from propitious, and the visitors had to forego a botanical ramble to the famous Falls of Ruthrie. This gave them, however, all the more time to spend with Mr. White, and a most enjoyable day was spent.

Obituary.

Andrew Russell Carlisle.—It is with deep regret that I record the death of Mr. A. R. Carlisle, who had been in failing health for some time past. Of his earlier career I have no record, but for the past twenty years or more I have known him as a very keen gardener, especially in the cultivation of hardy fruits. The last position he held was that of gardener at Henlow Grange, Bedfordshire, and it was from these gardens that he won a large number of prizes at the R.H.S. shows held at Vincent Square. He was also a successful exhibitor at Belfast, where he was awarded a Silver Cup and £10 for a large collection of Apples. Mr. Carlisle was on several occasions awarded first prizes in the county classes at Vincent Square, both for Apples and Pears, and was very successful in single dish classes, and one cannot help remembering a wonderful dish of Peasgood's Nonsuch that gained him the first prize in the year 1911. One fruit alone weighed 1 lb. 11½ oz. Although he retired in April, 1920, his interest in the cultivation of hardy fruits continued, for having purchased a house in the village of Henlow, with a good portion of land attached, he at once planted up his favourite varieties of Apples and Pears. During the past three or four years he was a most successful exhibitor in open classes, and secured the much coveted Hogg Medal. He was laid to rest in sight of his old home, and a large company assembled in the churchyard to show their respect for him. He was sixty-six years of age, and leaves a widow, one son and a daughter to mourn his loss. *T. P.*

Mrs. H. Dixon.—The deepest sympathy of Orchid-loving readers will be extended to Mr. Harry Dixon, of Spencer Nursery, Wandsworth Common, who has sustained a heavy bereavement in the death of his wife, who passed away on Sunday afternoon last, following a severe operation.

Lt.-Col. George Henderson, M.D.—The death is announced from Inverness of George Henderson, who conferred many benefits, scientific and administrative, on India. Born at Cullen, in November, 1836, he had reached a venerable age. A graduate of Aberdeen University, where he had a most distinguished career in medicine, Dr. Henderson joined the old Indian "John Company" two or three months before that Company's administration was taken over by the British Government, his first post being at Sialkot, Punjab. Soon after he became Professor of Surgery in Lahore University, of which he remained a warm friend all his life. His administrative qualities were tested when he became Superintendent of the Central Jail, Lahore. He revolutionised the system of prison treatment then in vogue with beneficial results to all concerned. In 1870, Dr. Henderson was selected as medical officer, with special authority to collect scientific information concerning the flora and fauna, to Sir Douglas Forsyth's mission to Yarkhand. The route lay through Kashmir, Ladak and Sanju, ultimately reaching an altitude of 19,600 feet. During the expedition, Dr. Henderson discovered several new species of birds, including Falco Hendersoni and Podoces Hendersoni, and many rare plants. Along with Mr. Allan O. Hume, Dr. Henderson published a narrative of the expedition, entitled *Lahore to Yarkhand*. He introduced into the work some remarkably fine specimens in those days of his own photographs, and coloured drawings of birds and plants. Returning home on a six-months' furlough, Dr. Henderson became a member of the Royal Geographical Society and also of the Linnean Society. His furlough was abruptly ended when the Government of India requested him to take up the post of Director of the Royal Botanic Gardens and Professor of Botany at Calcutta University. At this time Ipecacuanha was dying out in South America, and the Indian Government were anxious to try and grow it on the Cinchona (Quinine) plantations, near Darjeeling. Here, again, Dr. Henderson rose to the occasion. He imported two hundred plants, and in a year these multiplied twenty-thousand fold. Once more he assumed charge of the jail at Lahore, where he taught the prisoners the cultivation of vines, etc., and had the unique record of never having a case of cholera—so common then. From there, he was transferred to Rawal Pindi. Wherever he was placed, Dr. Henderson became honorary superintendent of the public gardens. He was responsible for the designing of a great part of the gardens at Lahore, while the whole of the public gardens at Amritsar were laid out by him. He found Shahpur a barren waste and left it a garden. Here his greatest service was rendered in the discovery as to which particular species of Eucalyptus tree would grow in India. This experiment he carried out with remarkable success, and years afterwards he was able to drive for thirty miles through a shaded avenue planted by himself, and where formerly there had been a desert.

ANSWERS TO CORRESPONDENTS.

Aster Stem-rot.—*W. H. M.* The disease in the Asters due to the fungus Phytophthora cryptogea. Destroy all badly infected plants and water the remainder with Cheshunt compound. Bear in mind that soil will be infected and that susceptible plants should not be grown in it before it has been sterilised with either two per cent. formalin for outside borders, or steam for potting soil.

Calanthes Unhealthy.—*A. S.* The Calanthes are suffering from the effects of an atmosphere overcharged with water vapour. The black spots on the foliage are due to a bacterium which becomes active when the relative humidity figure in the house is high. Restrict the amount of water used in watering and damping down, so that the air in the house is drier, which will allow the plants to recover from the setback.

Cypress Shoots Unhealthy.—*H. I. W.* The Cypress shoots are free from attack by pathogenic organisms. The trouble is probably due to dry conditions at the roots, which would cause many of the shoots to die back.

Factors Governing the Development and Flowering of Vines.—*A. L. B.* Various causes conspire to bring about the development of a healthy and fruitful vine. During the whole season of active growth the atmosphere of the vinery should be kept moderately moist in order to encourage strong and healthy growth. This is secured by syringing the vines until growth has commenced, damping the walls and paths at least twice daily on bright days, and by maintaining a steady temperature commencing with 48° when starting the vines into growth, and gradually rising to 65° at night, always allowing a rise of 5° to 15° during the day, according to the outside atmosphere. A well-drained border, thin training, by the removal of all superfluous shoots and laterals, moderate cropping, with careful watering, feeding and ventilation, are all necessary details to bring about healthy and fruitful vines. A few causes which conspire to bring about failure are that the border is often at fault, the soil being sour or exhausted; too many spurs left on the vines, with consequent overcrowding of the foliage; laterals and sub-laterals allowed to run wild; overcropping, and the removal of too much growth at one time, all of which factors prevent the proper development of the fruit buds. Another frequent cause of failure by amateurs is crowding the vinery with tender plants through the winter months when the vine ought to be at rest.

Grapes Shanking.—*A. H.* The Grapes show signs of "shanking," which is due to an insufficient amount of water during the period of swelling. The spots arise from draughty conditions, so that careful attention must be paid to watering and ventilating.

Iris Sibirica "Perry's Blue" Diseased.—*M. T.* The plant of Iris Sibirica is affected with a fungus disease similar to that to which the Bearded Irises are subject. At least two species of fungi are present in the roots and work on this comparatively new disease is still continuing, so that it cannot be stated which fungus is the causative agent. The affected clumps should be lifted and destroyed and the soil surrounding them taken away and buried deeply in some other part of the garden.

Lilium candidum Diseased.—*F. T.* The plants of Lilium candidum are attacked by the fungus, Botrytis cinerea. Plants growing in exposed positions are very susceptible to attack, the fungus making headway when the plants receive a check in growth such as may be induced by cold draughts and late frosts. The attacked bulbs should be lifted and burnt. Lift all the bulbs after the growing period, dust them with green sulphur, and replant in a sheltered position and away from the influence of northerly and north-easterly positions.

Malva Flowers Lacking Colour.—*C. W.* The cause of the lack of colour in Malva and other herbaceous plants may be due to the absence of ferric salts in the soil. The trouble may be remedied by the application of iron sulphate to the soil at the rate of two to three ounces to the square yard. There are white varieties of Dictamnus and Thalictrum, and the presence of white flowers on these plants may be normal.

Names of Plants.—*M. P. S.* 1, Sempervivum ciliosum; 2, Crucianella stylosa; 3, Campanula cochlearifolia var. alba; 4, Campanula cochlearifolia; 5, Campanula Portenschlagiana; 6, Sedum spurium; 7, Sedum Ellacombianum; 8, Veronica Guthriana; 9, a form of Dianthus caesius; 10, Dianthus hyssopifolius.—*W. Y. Z.* 1, Hippophae rhamnoides; 2, Euphorbia Wulfenii; 3, Allium Moly; 4, Phlomis grandiflora; 5, Phlomis fruticosa; 6, Poterium obtusum.—*S. S.* 1, Lonicera Caprifolium; 2, specimen too poor to identify; 3, Polypodium alpestre.—*G.* 1, Salvia candidissima; 2, Heuchera sanguinea; 3, Genista sagittalis; 4, Rodgersia pinnata; 5, Stachys grandiflora; 6, Spiraea Aruncus; 7, Dorycnium hirsutum; 8, Philadelphus Lemoinei var. erectus; 9, Stevia serrata; 10, Philadelphus coronarius; 11, Jasminum primulinum; 12, Ligustrum vulgare; 13, Clematis Viticella; and 14, Dianella sp., insufficient material.

Pansy Plants Diseased.—*G. G. H.* From the appearance of the Pansy plant, it is suggested that it is suffering from drought as there is no sign of attack by any parasitic fungal organism. The maggot is the larva of a midge, Sciara species, which feeds on decaying organic matter, and is not connected with the trouble.

Preparing Cheshunt Compound.—*A. W. B.* Cheshunt compound cannot be secured ready prepared, but may be made as follows:—Mix two parts, by weight, of powdered copper sulphate with eleven parts of finely crushed, fresh ammonium carbonate, and store it in a tightly-corked glass or stone jar for twenty-four hours. Dissolve one ounce of this dry mixture in a little hot water, and add it to two gallons of cold water. It should be used immediately after being prepared (only sufficient for immediate requirements should be mixed) and should not be put into iron, tin or zinc containers, as it corrodes them and loses its strength. This fungicide originated at the Cheshunt Experimental Station, hence its name.

Rose Leaves Attacked by Slug-worm.—*A. H.* The Rose leaf has been attacked by the Rose Slug-worm, which is the larva of the sawfly, Eriocampa rosae. To prevent further damage in August by the second brood larvae, spray the lower surface of the foliage with one ounce of arsenate of lead paste to one gallon of water.

The Pruning of Apples.

THE experiments and observations on the pruning of Apples which have been carried out at East Malling for many years, have borne good fruit; an empirical art is rapidly becoming an exact science. It used to be the custom on the part of experts to lay down fixed and sometimes contradictory rules; now the first recommendation by the modern expert is that method of pruning must be adjusted to variety of Apple and kind of stock on which it is grafted. Thus there are certain varieties, of which Worcester Pearmain is an example, which possess a tip-bearing habit, that is, they produce many of their fruits not on spurs, but along the tips of the branches, and this habit is specially marked in the second or adolescent stage of the growth of the tree. To practice "leader tipping" unrestrainedly on this or similar "tip-bearing" varieties is to throw away the baby with the bath water. Yet leader tipping—the shortening of the shoots that extend the branches or form new branches—is essential for the shaping of the tree, the maintenance of its vigour and the furnishing of the branches with spurs. The advice on "leader tipping" given by Mr. N. H. Grubb in the summary of experiments at East Malling* is well worth noting and practising. In the young tree up to the fifth year, leader tipping should be drastic, that is, some two-thirds or three-quarters of each leader should be removed, but should become less and less as the tree takes shape. In the second or adolescent stage the object of pruning is different. The tree has been shaped. It must now be brought into bearing. If early bearing is the object, then leader tipping must be reduced greatly in severity, for if it be continued vigorously, although the mature tree will be more satisfactory, cropping will be delayed. How remarkably leader tipping may delay cropping is shown by the figures of experiments made at East Malling. The total crop in bushels per acre up to the ninth year was :—

	Leader tipped.	Not Tipped.
Early Victoria.. ..	173 ..	522
Grenadier	70 ..	209
Lane's Prince Albert ..	82 ..	242

Therefore, in the case of fillers, that is, trees planted for early cropping in order to provide returns pending the maturing of the permanent trees, tipping must be practised far more sparingly than in the case of the permanent trees. Yet, even in the case of fillers, leader tipping, albeit light, must be practised; for if it be neglected, the quality of the fruits will suffer. It is a well-known fact that the unpruned tree gives, in its early years, more fruit than does the pruned tree, but it is equally well-known that the fruits of the young unpruned tree are generally, if not invariably, inferior to those of the pruned tree. So in the case of the untipped young trees, particularly with Allington Pippin and Cox's Orange Pippin, the fruits produced, although numerous, are very small. The practice of tipping as applied to Apples is indeed essential to the conservation of vigour of the tree. Neglect it, and although much fruit of a small kind is produced in the early years, partial exhaustion follows, and the tree with unrestricted growth is soon surpassed in fruitfulness by that the growth of which was controlled by judicious "leader tipping." An application of this fact to old and neglected orchards would lead to great improvement in crop production. As Mr. Grubb points out, the trees of many of these old orchards are in like case with the untipped trees of new plantations. Severe pruning with a moderate "dehorning," that is, heading back of the main branches, would lead eventually to larger fruit—and often to more fruit. Nor should the pruner forget that he is at once a sculptor and a surgeon. He shapes the tree and by timely surgery he saves it from manifold diseases. Sometimes the salvation results from the removal of branches in which diseases—scab, mildew and canker—have ensconced themselves with intent to do harm in the future. The pruning knife and bonfire in winter scotch these snakes. But pruning, by making the tree easier to spray, permits of the destruction of insect pests and fungus diseases which otherwise would be protected by their inaccessibility. Yet again, by conserving the energy of the tree, pruning appears actually to enhance its powers of resistance to such diseases as scab and canker. Lastly, by letting light and air into the centre of the tree, pruning makes healthy trees which do not readily fall victims to disease. In view of the excellence of the precepts laid down by Mr. Grubb, we hope that this summary of East Malling pruning experience will be reprinted in pamphlet form for there are large numbers of amateur and professional gardeners who would like to have such a pamphlet by them for reference when the time for summer and winter pruning comes round.

Admission to Kew Gardens.—The charge for admission to the Royal Botanic Gardens, Kew, was imposed during the war, presumably for economic reasons and by way of a luxury tax. On five days of the week the public has had to pay one penny per head for admission, while on two days—students' days, Tuesdays and Fridays—the charge has been sixpence per head. On July 22, Mr. Noel Buxton, Minister of Agriculture, announced in the House of Commons that, commencing on August Bank Holiday, the charge of one penny for admission to Kew would be abolished; the charge on students' days will remain. It was stated in Parliament that the loss entailed by the abolition of the penny charge would be about £5,000 a year.

Moreton Paddox Gardens.—By kind permission of Captain and the Hon. Mrs. Garland Emmet, the above gardens were opened to the public on Sunday, July 14 from 2 p.m. to 8 p.m. It is twenty years since the mansion was built, and the gardens laid out by Major and Mrs. Emmet—parents of the present owner. The site which the gardens now occupy was formerly rough land covered by scrub and Gorse. Under the special care of Major Robert Emmet, this land was transformed into the lovely garden that it is to-day, almost every type of garden being represented in a very charming manner. How much the garden is appreciated is shown by the fact, that, although the charge for admission was only 6d., the gross takings for the afternoon was upwards of £175, which money will be divided among charitable institutions. Fortunately, although the crowd was big, it is pleasing to record that little damage was done, and the general behaviour of the visitors was excellent. This is gratifying, as it is pleasant for the mass of people living in towns, and garden-lovers, to have the opportunity of visiting these stately homes, and we hope that their periodical opening will become a permanent institution.

Roses in Street Decoration.—There are not many towns with an atmosphere sufficiently pure and free from dust to admit of Roses in their scheme of adornment, but this is apparently the case in a Berlin suburb where, greatly daring, Roses have been introduced into a small roadside plot. A long street, known as the Schönhauser Allee, leads from Old Berlin to Pankow, and just where (as "Berlin Street") it debouches on the suburb itself, certain alterations in the form of the street have left unoccupied a narrow strip, which has been turfed over and the centre portion planted in rectangular beds. Each bed, in the centre of which is a stone vase, has been planted with Roses, the kinds chosen being Rödhätte and Eblouissant. It will be interesting to see how this bold experiment will succeed, and whether the Roses will survive the inevitable dust of this particularly dry summer.

New Roses at Bagatelle.—The meeting of the International Jury at Bagatelle, Paris, was held on June 20, almost one week later than usual. This was due to climatic conditions which retarded vegetation to an ususual extent. It is pleasing to state this year, nothwithstanding the great severity of the winter, that the growths of all the Rose trees under trial 1928-29 were in good condition. Our correspondent states that he is satisfied that on no other of his many visits has he found the trees submitted for trial so satisfactory. They gave ample evidence of the preparation of the beds and the introduction of a fairly suitable compost for Roses, as the natural soil at Bagatelle is far from what the Rose requires. The trees planted in the autumn of 1928 were, as it was to be expected, not sufficiently advanced in growth to admit of critical examination; consequently, very many of those on trial were not in bloom, and were reserved for further notice. The chief attention of the Jury was centred on the 1928-29 trials and, as mentioned, good culture was in evidence on all the varieties under trial. It will be readily understood that all the fifty novelties planted for trial could not possibly be at their best on a particular day; indeed, quite a number were several days past their best condition; still, there was on most of them sufficient material to enable an opinion to be formed, and the conclusion arrived at after two days careful scrutiny was that only ten per cent. of those on trial were worth further consideration. The Gold Medal for the best French production was given to Madame Pierre S. du Pont, H.T., raised by C. Mallerin; colour deep saffron-yellow; of medium size and good form; possessing excellent habit and foliage, also very free-flowering. This variety was outstanding both in 1928, when it gained nine points out of a possible ten; and in 1929, when it received nine-and-a-half points. The First Certificate was awarded to Souvenir de Pierre Guillot; colour somewhat difficult to describe, being yellow at the base of the petals and coral pink at the edges. It received eight points on both occasions. The Gold Medal for a Rose other than French was awarded to Messrs. Leenders Deville and Co., for President Deville. This was seen at its best. It is very free-flowering, of medium size, good form, and deep rose colour; it should be a good bedding variety. The First Certificate was awarded to M. Pedro Dot for Frederico Casas, which resembles Juliet in colour, but is very thin. Other varieties noted as worthy of trial were Le Maréchal Petain, scarlet, of good form and free-flowering habit; Leni Neuss, pink on salmon ground, very attractive; Dr. Augustin Wibbett, a full flower, golden-yellow, shaded cadmium; Julie Strahl, capucine-red on a yellow ground, and very free-flowering; and Jules Gauyard, red, shaded carmine, of good growth and free-flowering.

---

* "Apple Pruning: Summary of Deductions from Experiments at East Malling (Revised January, 1929)," by N. H. Grubb. *Annual Report* 1.—*General.* East Malling Research Station, 1928.

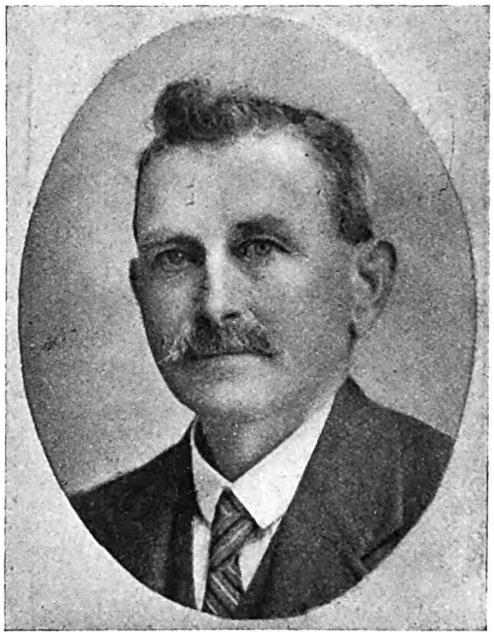
The Hardy Fruit Crops of 1929.—In accordance with our usual custom, we have invited numerous gardener-friends to report upon the amount and condition of the hardy fruit crops in their districts, and requested that the reports be returned to us without delay. We hope that outstanding reports will be returned at once.

Seed Firm's Staff entertained.—On Saturday, July 6, the employees of Messrs. Edward Webb and Sons attended the third annual garden party given by Major W. Harcourt Webb (Managing Director of the firm) and Mrs. Webb, at their residence, Spring Grove, Bewdley. The party, which numbered several hundreds, was conveyed to Bewdley in char-a-bancs and motor cars, and the grounds and gardens were thrown open to the guests. Luncheon and tea were served in a large marquee, and various competitions and games, including bowls, tennis, clock golf, cricket, football, skittles, a whist drive, tug-o'-war, fishing in the lakes, etc., kept everyone in a state of pleasurable excitement throughout the day. Music was provided by the band of the 8th Worcestershire Regiment, and in the evening there was dancing on the lawn. The weather was delightful and a most enjoyable day was spent. At the close of the proceedings, on the motion of Captain J. Clayton (Director), a vote of thanks was enthusiastically accorded to Major and Mrs. Webb for their generous hospitality.

A Cheap Shading Material.—A German contemporary, *Die Gartenwelt*, for July 12, contains directions for the shading of large expanses of glass with a wash made of ordinary clay and water. The clay is lightly dissolved in the water, and then spread over the glass roofs by means of a coarse-rosed watering can. This wash, naturally, will not withstand rain, and in many cases it is useful that it should thus be removed; but if it is required to last all the summer, a couple of handfuls of lime may be mixed with every twenty pints or so of the clayey mixture. Although this will withstand ordinary rain, it is much easier finally to wash off than lime-wash alone, as well as being considerably cheaper.

Further Acquisition of Land in the Lake District—It is with very great pleasure we learn that Mr. and Mrs. Noton Barclay have purchased the Ings and Stable Hills and generously presented the land to the National Trust. This area extends along the south-west side of Derwentwater from Strandshag Bay to Scarfclose, and will thus keep open to the public many fine views of a lovely lake. It is expected that the field known as Strandshag will soon be purchased, as most of the purchase money has been donated. This will link up the foreshore of the newly-acquired property with that already secured northward, so that eventually there will be a public lakeside walk of nearly two miles.

Mr. John T. McCormack.—At the age of fifteen, Mr. J. T. McCormack commenced his horticultural career under the very excellent training of Mr. Charles Kershaw, at Syke Nurseries, Brighouse, Yorkshire. He received invaluable tuition from the founder of the firm, who believed in having everything done in a most thorough and practical manner. He remained with the firm eighteen years, gaining a wide and valuable practical experience in the various horticultural departments and making a special study of landscape gardening. From Brighouse he entered private service, spending five years as head gardener at Huddersfield, and three years at Calverley. He then started business on his own account as a landscape gardener, his past experience enabling him to carry out with success the laying-out of many private gardens, and the construction of rock gardens, bowling greens, tennis courts, etc., in Huddersfield, Bradford, Leeds and Pudsey. Having many calls for advisory work in all branches of the profession, Mr. McCormack removed to Harrogate, where he undertook the lay-out of four acres of ground at Rossett Acre, consisting of rock gardens, Rose garden, tennis and ornamental lawns, kitchen garden and orchard. He still carries on business as landscape gardener and consulting horticulturist, specialising in hardy plants in general, alpine plants and Roses in particular, and garden construction, with a special leaning towards the making of Rose, rock and formal gardens. Before removing to Harrogate, he became President of the Bradford and District Professional Gardeners' Association, and at the same time he was on the committee of the Pudsey and District Chrysanthemum Society, and was made a life member for services rendered. He took part in the formation of the Harrogate and District Horticultural Association, this being the third year of its existence, became Vice-Chairman and subsequently Chairman. Last January, he was honoured by being elected for the fifth year in succession as President of the Professional Gardeners' Association, which has now a goodly membership.



MR. J. T. McCORMACK.

A Giant Fasciated Thistle.—We have received from Messrs. Carter Page and Co., Ltd., a curiously fasciated Thistle, which was brought to them by Francis Gibbs, Esq., of Wales. The combined, flattened stems measure three inches across at the base, and four inches across at one foot, where the stems divide into two fasciated branches, one-and-a-quarter-inch and two-and-three-quarter-inches across, respectively, each crowned at the height of twenty-two inches with large clusters of inflorescences, and the whole being densely covered with foliage.

Opening of Charlton Park, Greenwich.—On Saturday, July 13, Lord Monk Bretton presided over an influential gathering when the Lord Lieutenant of London, Lord Crewe, opened Charlton Park, Greenwich, to the public. The park originally formed part of the grounds of Charlton House, which, it is stated, was erected for the occupation of Prince Henry, eldest son of James I. Practically the whole of the forty-two-and-a-half acres which has been acquired at a cost of £22,250 by the London County Council, has been laid out for games and sports. In addition to cricket, football and hockey pitches, grass lawn tennis courts and pitches for netball, a running track has been made at a cost of £2,000. The total cost of laying out the Park, including the track, was £15,000. An additional three acres is to be used for the provision of an open air school.

Legacies to Gardeners.—The late Mrs. Frances Helen Maria Jacobs, of Fairfield, Lower Shiplake, Oxon., who died on March 27, 1929, left £500 to her late gardener, Mr. Francis John Fuller.—The late Mr. William Dale Shaw, J.P., of Homefield, Longwood, Huddersfield, who died on April 12, 1929, left £120 to his gardener, Mr. John W. Ascough, if still in his service.—The late Mr. James Henry Sadler, J.P., D.L., of Lydiard, near Swindon, who died on March 27, 1929, left £50 to his gardener, Mr. Newman.

The Destruction of Wasps.—The damage done to fruit crops annually by wasps is enormous, so that the small booklet entitled *Wasps and How to Destroy Them*, by J. D. Wrangham, B.A., and published by the Pilot Press, 2, Little Essex Street, Strand, W.C.2, price 1s., should be welcomed by all gardeners and fruit-growers. Mr. Wrangham devotes a chapter to "Situations and Methods of Finding Nests," giving sound advice upon the methods to be adopted in the tracking of wasps to their nests, and he then proceeds to deal with the destruction of the nest. The three practical mediums for this purpose are poison, preferably in the form of cyanide of potassium or cyanide of soda; tar, and fire. The two poisons advised may be procured from any chemist for the purpose at 8d. per ounce; they are exceedingly dangerous, and should not be left about or entrusted to children; as they deteriorate rapidly in air, they should be kept tightly corked. For general purposes these cyanides are best in lump form. The directions for use are:—Place a lump of the poison (about the size of a man's thumb-nail) in a spoon attached to a stick, fill the spoon with vinegar, and deposit the two in the entrance hole of the nest. The fumes given off will kill the wasps directly they come into contact with them. This is by far the cleanest and most humane method. Tar is the cheapest and simplest method, while, when nests are awkwardly situated, burning with the aid of paraffin at night may have to be resorted to. The various methods to be adopted are described in detail, and we recommend Mr. Wrangham's booklet to all gardeners as a handy little reference work to keep by them.

Parks Superintendents' Conference at Manchester.—There could have been no better place than Manchester in which to hold the annual meeting and conference of the Association of Parks and Botanic Gardens Superintendents, for not only has Manchester a very fine public parks department and system, but the Superintendent, Mr. W. W. Pettigrew, is well-known throughout the kingdom as one of the finest of organisers, administrators and cultivators that adorn the horticultural profession; Mr. Pettigrew is the President of the Association for this year. The Conference was well attended by members from many parts of England, Scotland and Wales, and by various Chairmen of Parks Committees who received invitations to attend as delegates. This association of Superintendents and Chairmen is an ideal one, because in not a few instances the latter are also horticulturists; if they are not, their meeting with the leading Parks Superintendents of the kingdom can have nothing but good results both to themselves and to the towns they represent. The delegates were received by the Lord Mayor of Manchester, Col. E. Westcott, and the various parks under the control of the Corporation were visited. The Conference proceedings lasted from July 8 to July 10. The Secretary reported that the membership is 140. The Treasurer's Statement of Accounts showed a balance in hand of £154. The following officers were elected for the ensuing year:—President, Mr. W. Besant, Glasgow; Vice-Presidents: Mr. W. W. Pettigrew, V.M.H., Manchester, and Mr. T. Hay, V.M.H., Hyde Park; Hon. Secretary and Treasurer, Mr. A. Blackburn, Blackpool. Papers were read by Mr. R. B. Dawson, M.Sc., Director of Research of the J. A. C. of the Golf Union on "Some Green-keeping Problems and the Programme of the Research Board"; by Mr. Councillor W. Melland, Manchester, on "The Playground Movement and its Relation to Parks Departments"; by Mr. J. T. Jeffrey, Edinburgh, on "The Preservation of Town Amenities," and by Captain B. H. MacLaren, on "The Parks of Paris and Brussels." On Tuesday afternoon the delegates visited the Parks of the City of Salford, and on Wednesday the Parks of the City of Manchester, and in both cities there was much of interest to be found in what is being done by the Parks Departments for the physical and mental welfare of the citizens by the provision of facilities for the various forms of outdoor recreation both for adults and children, and by the horticultural displays which are maintained at a very high standard.

Forestry Congress in Stockholm.—The International Congress of the Union of Experimental Forestry Institutions was opened at Stockholm, on Tuesday, July 23, by the Prime Minister, Admiral Lindman. Proposals were made for the strengthening of international co-operation in forestry. The President of the Congress, Professor Henrik Hesselman, pointed out that the science of forestry was wholly international, and served the entire human race. The Congress should, therefore, agree to standardised measurements and terminology. M. Flury (Switzerland) proposed the organisation of an International Bibliography of Forestry, and Señor Velasquez (Spain) proposed the establishment of a central bureau to assist international co-operation. M. Guinier (France) proposed an international organisation for the delivery of forest seeds of guaranteed quality and origin, in order to avoid the failures hitherto frequent owing to the use of inferior seeds.

Fruiting of Styrax Wilsonii.—Major Albert Pam writes from Wormley Bury, Broxbourne, Hertfordshire, as follows:—"In a note on Styrax Wilsonii by *North Wales* (see p. 46), he states that this species has not set seeds in his garden. Here, seeds have ripened regularly for several years, and I have a nice lot of seedlings, some over a foot high, raised from seeds sown the year before last. There are also at least a dozen self-sown seedlings coming up around my large plant which I originally placed under a south wall, fearing that the species might be tender. I am afraid that this dry, hot summer has been too much for it in this situation, and that it has received a bad check while other plants in the open have come through last winter and this summer perfectly."

Verbena corymbosa.—The plant which was exhibited by Mr. Clarence Elliott as Verbena species, C.E. 354, at the Royal Horticultural Society's fortnightly meeting on July 16, and received an Award of Merit subject to its being named (see p. 58), has now been identified as Verbena corymbosa, Ruiz and Pavon.

Appointments for the Ensuing Week.—MONDAY, JULY 29: Harrogate and District Horticultural Association's meeting. TUESDAY, JULY 30: Royal Horticultural Society's Committees meet; Alderley Edge and Wilmslow Horticultural and Rose Society's Show; Royal West Renfrewshire Horticultural Society's meeting. WEDNESDAY, JULY 31: Chesterfield Horticultural Society's Exhibition; Royal Lancashire Agricultural Society's Exhibition (four days). THURSDAY, AUGUST 1: Bideford and District Horticultural Society's meeting. SATURDAY, AUGUST 3: Benefield Horticultural Society's Show; St. Ervan and District Garden Show.

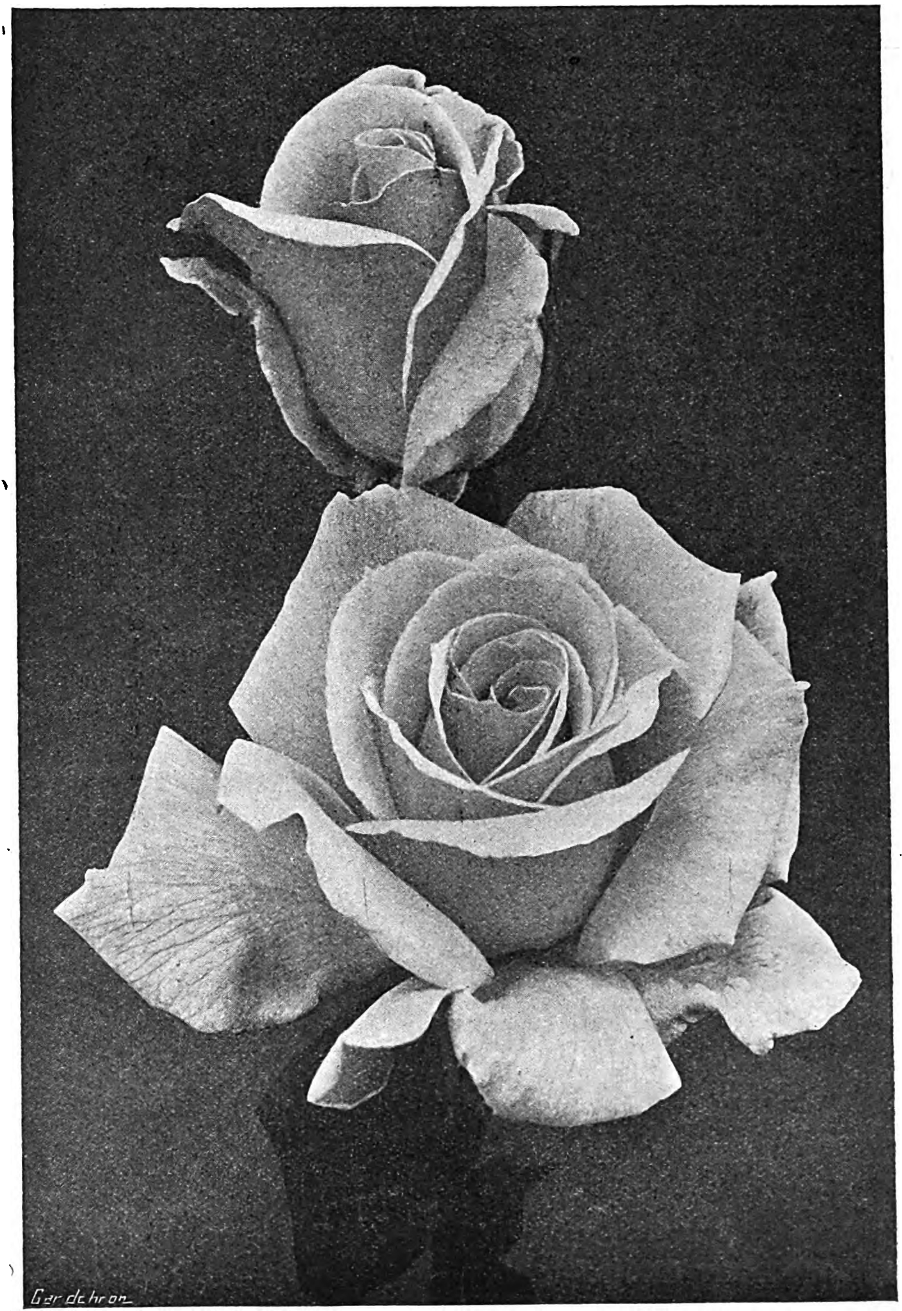


FIG. 29.—ROSE MRS. SAM McGREDY.

N.R.S. Gold Medal, Hereford, July 10. Flowers orange-red and apricot. Shown by Messrs. S. McGredy and Son. (see p. 55.)

"Gardeners' Chronicle" Seventy-five Years Ago.—*Preservation of Plant Sticks.*—One frequent complaint I have heard made by exhibitors is, that the constant tying and untying of plants, rendered necessary by the rotting of the sticks in pots, takes up much time, and gives much additional trouble. I myself have experienced this, and, consequently, was induced to try some experiments as to the best means of preserving the sticks. Having tried various preparations, a solution of gutta percha among the number, I find what painters call knot-varnish (or what they put on knots before painting the wood) to be by far the best; even some small sticks, not so thick as an ordinary penholder, have, after twelve months' use, appeared as sound as on the day they were put in. I simply dip the stick into a bottle of the varnish, and let it drain off. I think, on further trial, it will be found to bear out the above statement. The sticks, of course, when dry, can be painted any colour required; perhaps, however, some of your readers may know something even better than this; if so, I hope they will favour me with their experiences in the matter. *S. E. C., Cheltenham. Gard. Chron., July* 29, 1854.

Publication Received.—*C. R. S. and His Friends,* being personal recollections of Charles Roach Smith, F.S.A., and his friends; by Henry Smetham; pp. 252, illustrated; The C. W. Daniel Company, 46, Bernard Street, W.C.1; price 7s. 6d. net.

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN MOORE, Manchester.

Epidendrum prismatocarpum.—Specimens of this robust-growing and highly decorative Orchid have been making an attractive display of flowers for many weeks, and proving the lasting qualities of the flowers under moderately dry conditions. This is, of course, a great drain on the plants, and any that are not in a robust state of health should not be allowed to carry the flowers over a long period; the flower spikes should always be removed if any shrivelling of the bulbs is noticed. As in the case of most Orchids, weak plants that are allowed to flower take a long time to recuperate, and require a great deal of attention to bring them to a healthy growing state again; in most cases it is the best policy to remove the flower spike before any increased drain on the plant's strength occurs. On the other hand, if a scape is allowed to develop to the stage of opening its flowers, this often encourages fresh root-action, and keeps the plant to its proper season of growth; also there is less danger of the development of abnormal and twisted growths, which often occurs if the flower spike is removed in a very young stage. The damage is done when a weak plant is allowed to carry the spike for a period after the flowers have expanded. Robust and healthy plants will easily carry the strain until the flowers begin to fade, without any appreciable harm being done to them.

Potting and Compost.—After the flowering period of this evergreen Epidendrum is over, any necessary repotting may be done with a view to the plants remaining undisturbed for two or more years, as they resent root disturbance, and should only be repotted if the compost has become impoverished, or the plants have overgrown their receptacles. When repotting specimens, all useless back pseudo-bulbs should be removed, together with the decayed roots and old compost; two or three pseudo-bulbs, with each growing lead, are sufficient to retain to secure a well-balanced plant. If large specimens are desired, two or more leads should be arranged towards the centre of the receptacles, which should be well-drained. A compost of Osmunda and A.1. fibres, in a fairly rough state, and a little chopped Sphagnum-moss, should prove suitable, adding lump charcoal as the repotting proceeds. The compost should be pressed firmly among the roots. Water should be applied sparingly at fairly long intervals, so that the soil becomes dry between each application, until the roots are well established. So soon as the plants are growing well, more water will be needed at each application until growth is complete, when only sufficient to keep the plants in a normal state will be required. This Epidendrum thrives well in a light position in the intermediate house, and may be grown in association with the Cattleyas, as they require similar cultural treatment to the latter.

HARDY FRUIT GARDEN.

By HENRY H. COOK, Chief Assistant Lecturer, Reading University Horticultural College.

Strawberries.—To procure out-of-door dessert fruits early next year, the rooted plantlets should be afforded a position on a south border, and the earlier these are planted the better will be the prospects of obtaining first-class fruits next season. A border which was deeply dug and liberally manured during last winter, and has since carried a crop of early Peas or Potatos, should be suitable, the soil requiring but little preparation beyond an application of lime and a light digging. The soil should be made firm by treading, as the Strawberry favours a firm rooting medium. For this early supply of fruits the plants may be set out much closer than is general, cropped for one season only, and a fresh bed made annually. When all is ready for planting, see that the soil about the plantlets is thoroughly moistened. Lift the plants with all the roots possible, and plant them at intervals of fifteen inches, in rows twenty-four inches apart. Plant rather deeply, but not so deeply as to bury the crown or growing point. Make the holes deep and wide enough to accommodate all the roots, return the excavated soil, and make quite firm. These early plants will furnish dessert fruits a week or two in advance of the main beds, and are valuable in maintaining an unbroken supply after the indoor crop is over. The after cultivation will be to keep the surface soil constantly stirred, when in a dry condition, with the hoe or hand cultivator; and should the young plants produce runners, these should be promptly removed.

Varieties for Early Crops.—The most suitable varieties for this purpose are good strains of The Duke, King George and Royal Sovereign. The variety favoured by some of the Hampshire growers is Madame Lefebvre, which, they claim, ripens some days earlier than The Duke or Royal Sovereign. As soil and district are such important factors in the successful cultivation of the Strawberry, it is to be recommended that the newer varieties should be given a fair trial so that each grower may determine for himself what varieties will do best in his particular soil and district.

Raspberries.—Immediately the crop is finished, the old fruiting canes should be cut out close to the ground, and the best-placed canes thinly and loosely tied in to the stakes or wires. Cause so little damage to the young foliage as possible, and whenever practicable, afford the rows a copious watering, so that the canes may attain their full height. The variety Lloyd George is a wonderful cropper, producing very large fruits on the laterals almost the entire length of the cane, but Laxton's Bountiful has a much better flavour, crops abundantly, and is undoubtedly the strongest grower we have here. Pynes Royal is the best dessert variety, of very fine flavour, but of medium growth with us. Very few canes are produced, and the foliage is most distinct.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Late Peach Houses.—The trees in these look well, and, like the previous set, are now quite forward enough, as Peaches out-of-doors are late. Natural shade from the leaves and shoots will favour free development of the fruits, but shading later on will affect the colour and flavour adversely, as Peaches require plenty of light and air when passing through the final swelling stage to ripen them well and bring out their best qualities. Ventilators should be opened to the full extent, and closing of them deferred until the sun is off the house, while a little extra night air will assist in retarding the crop if this is necessary, as no retarding can be done after stoning is completed. The trees should be kept well supplied with water and stimulants, according to requirements.

Watering Outside Borders.—The rainfall in most parts of the country has been extremely light and quite inadequate to the requirements of vines and Peaches in outside borders. With such borders, composed as they are of porous materials through which water passes quickly, a timely watering is repaid over and over again by an improvement in the weight and quality of the crops, especially during the period in which the roots have to perform most of their work. The bulk of the watering should be done when the fruits are swelling and stoning, and growth is in full force. If the water is tepid, so much the better. The temperature of the water may be raised by exposure in open tanks for twenty-four hours. Where water is scarce a timely mulching of fresh stable litter, especially after warm thunder showers, will often render artificial watering unnecessary, but in a season like the present a timely watering gives the trees a step forward, which cannot be afforded in any other way. The spread of red spider, the premature dropping and ripening of Peaches, and the shanking of Grapes, is often due to dryness, or a system of applying driblets of water, but the mischief does not end there, as the roots descend in search of moisture, with the result that both the vines and Peaches whose roots are forced down become gross and unmanageable, and some considerable time must elapse before they can be restored to a fruiting condition.

Pot Vines.—Those intended for starting in December will now be swelling their buds, and the canes will soon be changing to the bright brown colour which indicates ripening. This process must not be hastened too much. Feeding and syringing should be continued, but more air should be given gradually, and the house kept slightly drier through the night. So soon as the canes, which should be stopped at six to nine feet, have coloured their whole length, a few of the lateral growths may be removed close to the main buds, commencing at the base and working gradually upwards. A few should be left near the top to run wild, and each main leaf should be carefully preserved to prevent the buds from breaking prematurely. If the season remains congenial, the vines may be removed later and secured to a south or west wall in the open air to ripen, or kept in a house ventilated as for early vines.

THE FLOWER GARDEN.

By R. FINDLAY, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Lavender.—Flowers of the Lavender for preserving for perfume purposes should be gathered when they are open; they should only be cut when the bushes are dry. The drying process should then be carried out slowly and not in full sunshine, or much of the essential oil which provides the perfume will be lost. Immediately after the flowers are gathered, clip the bushes with hedging shears to keep them neat and compact. For low hedges, dividing lines, or for covering dry banks, Lavender is an admirable and useful subject.

Spring Bedding Plants.—Plants for this purpose that have been raised from seeds, as Wallflowers, Sweet Williams and Canterbury Bells, and also the various perennials that were sown early, are now large enough to be transplanted to nursery lines. Do not transplant into very rich ground, which is conducive to soft, sappy growth; such plants do not winter so well as those grown on poorer soil. If the weather is dry, frequent good applications of water will be required until the seedlings become established, after which the constant use of the Dutch hoe will ensure firm, healthy growth.

Climbing Roses.—These are now making rapid growth, and the young shoots required for next season's flowering ought to be carefully tied in to prevent damage by wind. This applies more to the Wichuriana group than the others, as so much depends on being able to have vigorous young growths every year to replace those that have flowered.

Hedges.—These, in the majority of cases, may be clipped now; in fact, it is an advantage in some cases if this can be done frequently; by doing so a closer hedge is obtained more quickly than with only an annual clipping. A well-grown and well-cared for hedge is an ornament to any garden, but how often do we see them in poor condition through irregular clipping. When clipping hedges, cut close; a very large percentage of hedges are spoilt through neglect of this. It is quite an easy matter to put in a few stakes and stretch a line along them as a guide to cutting, and this well repays the extra trouble involved. Take special pains to leave the top level as this usually catches the eye first. A common fault is to be found in having hedges wider at the top than at the base. This is accounted for by the growth being stronger at the top, and clipping is more difficult for a man standing on steps or trellises than on the ground. Yet every endeavour should be made to keep hedges wedge-shaped; a hedge with a narrow top is less likely to be damaged by heavy falls of snow during winter.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Mignonette.—This delightfully scented annual always attracts attention when grown in pots under glass, and is extremely useful for the decoration of the conservatory. Seeds may be sown now, and again during September. The seeds are probably best sown in the pots in which the plants are to flower, as Mignonette does not transplant too readily. The receptacles should be clean and well-drained, and the compost should consist chiefly of good, rich loam, with a good proportion of old mortar-rubble added to keep it open and porous. In fact, lime is essential for the successful cultivation of Mignonette. The compost should be in such a condition as to allow it to be made tolerably firm. While some growers prefer to sow the seeds in sixty-sized pots, so that they may, in due course, move the plants on into six-inch pots, others prefer to sow them directly in the flowering pots; the latter method is quite satisfactory, provided careful watering is practised. After sowing the seeds, stand the receptacles in a cold frame, and provide shade from bright sunshine until germination takes place, when the seedlings may be thinned out to four or five in a pot. Watering should be done with care until the receptacles are well filled with roots, and even then care is needed; air should be admitted freely at all times. During the winter, the plants should be given an airy positon near the roof-glass; a house from which frost is only just excluded will suit them best.

Cyclamens.—Seeds of this popular plant should be sown now to provide plants for flowering next year. The soil should be well watered several hours before sowing takes place. The compost should be light in character, and the seeds so arranged that the most forward plants can be removed without unduly disturbing others that have been slower in germinating, as they are generally irregular in this respect. Stand the seed-pan in an intermediate house, cover it with a piece of glass and afford shade until germination takes place, when the seedlings should be grown near the roof-glass during the dull months of the year. The advanced seedlings should be pricked off into pans or boxes when they are large enough to handle, and potted off singly into thumb pots in a light, open compost when this becomes necessary.

Lilium candidum.—This fine old plant may be successfully grown in pots for decorative purposes, provided the plants are kept at all times under the coolest possible conditions. If success is to result, it is essential to obtain strong, healthy bulbs, and pot them during the present month. As this species does not root from the stems the bulbs should be little more than covered. After potting, stand the pots in a cold frame so that the lights may be placed over them during wet weather. Make no attempt to coddle this Lily.

THE KITCHEN GARDEN.

By W. G. STAWARD, Gardener to LADY MARGARET RYDER, Knowle Gardens, Dunster, Somerset.

Turnips.—A further sowing of white, yellow and coloured varieties should be made now. Thin the plants so soon as they are fit to handle, and after thinning, stir the soil between the rows with the hoe.

Spring Broccoli.—The ground for Broccoli should be manured well and dug deeply. The plants should now be ready for planting in their permanent quarters. Arrange the varieties in rotation, according to their season, so that when they are ready for cutting the ground may be cleared and prepared for the next crop at once. It is wise to grow several varieties of Broccoli so as to discover those best suited to the district, as some varieties do better in certain areas and suit the soil better, than others.

Onions.—If intended for the production of large bulbs, Onions should be kept free from weeds; the hoe should not be used, the weeding being best done by hand. Feed the plants regularly every week with liquid manure, and if the weather continues very dry, spray the plants overhead in the evenings. Should any of the plants be badly attacked by mildew, remove and burn them; this disease usually puts in an appearance if the soil is allowed to become too dry. If the plants have been mulched properly and watered regularly they are seldom troubled by this disease. To check mildew, spray the plants with a solution of sulphide of potassium (one ounce to three or four gallons of water). Sulphide of potassium may be procured from any chemist; it is cheap, but very strong smelling, and should be kept in an air-tight box.

Celery.—Early Celery is now growing fast and earthing up should be proceeded with. A light application of an approved fertiliser, and a thorough watering should, however, be given a day previous to performing this operation.

FIG. 30.—ROSES AND IRISES COVERING A BANK IN A PROVENÇAL GARDEN.
(see p. 67.)

Swedes.—When thinning Swedes, a few of the seedlings may be transplanted. These should be kept well supplied with water until they become established, when frequent stirring of the soil between the rows with the Dutch hoe will prove beneficial.

FOR NORTHERN GARDENERS.

By JOHN HILL, Gardener to ANDREW ARTHUR, Esq., Rosemont, Monkton, Ayrshire.

Vegetables.—When lifting early Potatos, it is advisable to select sets of a suitable size from the best stools only, if the strain is to be kept up to the mark. Plants with a goodly number of evenly-sized tubers, without many under-sized specimens, should be chosen. These seed tubers are best lifted green (or unripe) and laid out in boxes to weather before storing, as, when so treated, they start away earlier than matured tubers. Ground cleared of early crops should be planted with Leeks, late Cabbages, Asparagus Kale, or early Cauliflowers. Summer Spinach may also be sown to provide a crop for autumn use, while seeds of Globe Beet may still be sown on an early border. Cultivate all crops regularly so long as it is possible to get among them without damaging the leaves.

Cuttings.—For rooting cuttings of alpine plants and many kinds of shrubs and also herbaceous plants, a cold frame should be prepared, placing a layer of compost consisting of equal parts of loam, leaf-mould and sand in it and covering this with a layer of pure rough sand, about half-an-inch deep, making the whole quite level and firm. Soft cuttings, which will root in a few weeks, should be kept apart from those of more woody subjects, which will take much longer to root. They all, however, will require similar treatment. Do the work speedily to prevent wilting of the cuttings, and water them directly they are inserted. I have proved that a thin coating of whitewash on the glass is much to be preferred to mats, as it prevents burning while allowing the heat of the sun to warm the interior of the frame, thus greatly accelerating the rooting process. The sashes should be kept closed, even on the hottest day, air being given during the cool of the night, when no wilting will take place. Spray the cuttings frequently. Where heel-cuttings of shrubs can be secured, these should be used, and in all cases short, well-grown growths should be secured in preference to soft, thin wood. In ten days or a fortnight the softer growth-cuttings should be given more air gradually, until normal conditions are reached. Where a frame is not available, quite good results may obtained by digging a pit or hole in the ground, about one foot in depth, and making a cutting bed as advised above in the bottom of it. After inserting the cuttings and watering them in, a strip of scrim canvas should be stretched over the top and secured all round against wind; if this is kept frequently moistened it prevents too rapid moisture evaporation, and gives a certain degree of closeness necessary to root formation. A position not likely to be flooded, with a good, open subsoil, is necessary for this latter purpose.

Pyrethrums and Paeonies.—Should these require transplanting, now is a suitable time to attend to them—just as they pass out of flower. The ground to receive them should be double-dug and manured heavily, as both are gross feeders, especially Paeonies. Divide the crowns carefully, and should the weather be dry afford plenty of water at the roots and damp the foliage well in the evenings until root action is proceeding again. Pyrethrums should be divided with a sharp-edged tool, but care must be taken not to shake the roots free of soil, or the plants may receive too great a check.

PLANTS NEW OR NOTEWORTHY.

HELIOPHILA INTEGRIFOLIA, LINN.

A CRUCIFEROUS plant received recently at Kew for determination from Messrs. Sutton's Trial Grounds at Slough proved to be a species of Heliophila. As the plant promises to be of considerable decorative value for the cool greenhouse, its precise determination and botanical history seem to be desirable. At Slough it is at present grown in hanging baskets for which it is particularly suitable with its long, gracefully arched branches and deep sky-blue flowers. Seeds were collected in South Africa by the Hon. Mrs. Ryder, of Durns, Beaulieu, Hampshire.

The species has a considerable botanical history. It was first described in 1763 by Linnaeus in the *Species Plantarum* (Ed. 2, pt. 2, p. 926) as Heliophila integrifolia. As the name implies, the leaves of the type specimen are entire; in examination of herbarium and fresh material, however, this would appear to be something of a botanical misnomer, as the leaves in the majority of cases are lobed to a lesser or greater extent. Specimens are found in which both types occur, the upper leaves, and those on young plants, being entire, and a gradual transition is found to exist from these to deeply-lobed leaves. It would, therefore, appear that this character is extremely variable and no great stress should be laid on the lobing of the leaves. However unfortunate it may be that the type described by Linnaeus should be peculiar in this respect, there can be no doubt as to the identity of plants referred to the same species, and the name Heliophila integrifolia must remain.

In 1789, Linnaeus described the same plant as Cheiranthus africanus (*Amoenitates Academicae*, p. 90); as in Heliophila integrifolia the leaves are given as "lanceolate, entire." Lamarck in the same year described Heliophila pilosa (*Encyclopédie Méthodique Botanique*, III, p. 90), which may be undoubtedly considered as synonymous. Here the lobing of the leaves is noted, for to quote Lamarck's own words, "*Quelques individus se trouvent, à la vérité, à feuilles toutes très entières; mais la plupart ont des feuilles, les unes entierès et les autres découpées même profondément vers leur sommet.*" Probably on account of the more appropriate name, the plant has been known as Heliophila pilosa since the time of Lamarck. Sonder, in the *Flora Capensis*, maintains this species, and although he describes the leaves as "entire or sometimes lobed near the apex," he creates, among others, the variety integrifolia, with entire leaves, to which he refers the original Heliophila integrifolia, L. The distinction between his varieties, however, is not tenable, and the species should be considered a variable one, to which the oldest name of Heliophila integrifolia must be given.

From the above short historical account it is seen that the plant has been known for a very long time. It is an annual and native exclusively of South Africa. The branches are long and drooping, gracefully upturned at the apex, glabrescent, or more usually covered with long, spreading, white hairs. The leaves, which are alternate as in most members of Cruciferae, vary from about 1—6 cm. in length; they are lanceolate to oblanceolate, acute to subobtuse, at the apex, narrowed to a subsessile base, entire or three or more lobed towards the apex, in some instances the lobing reaching almost to the base, glabrous or hirsute as the stems. The inflorescence is an elongated raceme, terminal on the main and lateral branches. The pedicels, barely 1 cm. long in flower, lengthen slightly in fruit, and are softly pubescent as are also the sepals; these have a narrow, membranous margin, and the lateral pair are but slightly saccate at the base. The flower is open, with the petals spreading, and measures about 1·5 cm. across; the petals are obovate in shape, a beautiful bright blue in colour, with a green, white-edged patch at the base and a lateral nectary. The mature siliqua is about 6 cm. long, cylindrical, with straight margins or slightly torulose, capped by the persistent swollen base of the style. *Marion B. Moss, Kew.*

[In our issue for June 22, Fig. 233, p. 461 (Vol LXXXV), we gave an illustration of a plant which received an Award of Merit from the R.H.S. on June 11, under the name of Heliophila linearifolia, and this has since been determined a H. longifolia, *D.C.*; it is, apparently, distinct from the plant here described. EDS.]

INDOOR PLANTS.

ABUTILON MOSAICUM.

UNDER the name of Abutilon mosaicum a useful greenhouse shrub is occasionally met with, yet it is a plant of merit which flowers freely from spring until autumn, and seldom fails to yield a few blossoms during the remaining part of the year. At first sight it is not unlike A. megapotamicum, but the sepals of the flowers are shorter, giving them a singularly beautiful, shallow-campanulate appearance. The tessellated leaves are mottled with yellow in true mosaic pattern, and here this feature of plant life, so much dreaded in some races of plants, fills the purpose of added beauty in this particular species.

Of relatively slow growth, A. mosaicum eventually makes a bush of considerable size, and there is an example in the conservatory at Warwick Castle which is an object of rare beauty. Some ten feet high, with an umbrella-like spread of eight or ten feet, and carrying many hundreds of its campanulate flowers, which hang like myriads of miniature Chinese lanterns, it compels admiration. The flowers are of that deep brick-red shade which is so appealing in a flower, and the mosaic foliage adds to their charming setting. *A. M. W.*

FREESIAS FOR MARKET.

THERE are some flowers which are well worth growing, not only for their beauty, but also from a commercial point of view, and the Freesia may justly claim to be in this category. Year by year millions of Freesia corms are grown for market, but to get the best prices for blooms, the bulbs should be planted so soon as obtained.

With regard to the methods of cultivation, those adopted by Guernsey growers are worthy of note. The corms are planted in boxes two feet long by one foot wide and four inches deep. About seventy to eighty first-size corms, 120 second-size, or 150 (sometimes more) third-size corms are sufficient for boxes of this size. Some old, decayed manure is put into the boxes to a depth of about one inch, over this well-worked garden soil to a depth of about one-and-a-half inch spread evenly, and the corms are placed on this, and covered to a depth of one inch. The boxes, when planted, are placed in a sheltered position; on no account is the soil allowed to become dry.

In four or five weeks' time, when so planted, the growths commence to peep through the soil. Beyond weeding and watering, nothing more is required until the first week in November, when they should be removed to a greenhouse. If there is a congenial temperature in the house the plants will commence to bloom in January, but if the house has no heat at all, the flowers will not appear until February or March.

If the Freesias do well, as they should do under these conditions, they should produce at least four times the quantity of corms planted; for example, suppose one bucketful of corms is planted, then one may expect four times the quantity as the crop, unless they are heavily forced—the use of artificial heat does not, as a rule, result in first-size corms. The largest will only be considered in the trade as "seconds," and should be planted out for one year.

Although F. refracta var. alba is the variety most sought after, the mixed sorts are coming into prominence with market growers, chiefly because many are constitutionally stronger and more sweetly-scented than F. refracta var. alba.

Where the Freesia is only grown for the production of blooms, the second and third size corms will be quite good enough for this purpose. *G. B.*

TREES AND SHRUBS.

AESCULUS INDICA.

THE Indian Horse Chestnut, as this tree is commonly termed, flowers a month to five weeks later than the Common Horse Chestnut, and, although a native of the Himalayas, a number of trees of it at Kew withstood twenty to twenty-five degrees of frost last winter without damage to a single twig. Several trees have flowered freely, one in particular, near the Refreshment Kiosk, being covered with the cylindrical panicles of white blossoms flushed with rose. Even when not in flower the luxuriant, shining, dark green foliage of this Aesculus gives it a value surpassing that of the Common Horse Chestnut for ornamental purposes.

Now that good seeds are produced on the Kew trees, and elsewhere, in most seasons, would-be planters should have no difficulty in obtaining trees for pleasure ground, avenue and park planting. The Indian Horse Chestnut promises to equal in size the Common Horse Chestnut in all but the coldest parts of Britain. As a wild tree in Northern India, it is stated specimens have been measured exceeding one hundred feet in height. *A. O.*

OLEARIA GUNNIANA.

THIS Tasmanian Daisy Bush is a shrub with several aliases. The medley of names is somewhat disconcerting to anyone who may find it masquerading as Eurybia stellata, or Olearia stellulata. Despite a doubtful reputation for hardiness, it came through the past severe winter in a Glasgow garden almost unscathed. Indeed, the experience would seem to have spurred it to exceptional effort, for seldom has it been so florally effective as during the past few weeks. The loose, Michaelmas Daisy-like heads of white, yellow-disked blooms, which, individually, are an inch in diameter, borne at the apices of the previous season's growths, are conspicuously noticeable in the shrub border, the effect being enhanced by the environing, darker foliaged subjects.

Olearia Gunniana is of hoary appearance, by reason of the silvery tomentum coating the leaves and stems of the young shoots. Apart from its decorative value as a single specimen, it is a showy subject for a hedge; not in the formal garden, where much trimming would be required, but for a position where its naturally dense and upright habit of growth would suit the special requirements without the too frequent use of the knife. *Jonathan Fiona.*

HARDY FUCHSIAS.

IT is claimed that many of the new, large-flowered hybrid Fuchsias are perfectly hardy, but it is only in favoured localities in the south that they make handsome bushes or ornamental hedges, and although under less favourable climatic conditions they may survive the winter and become, in effect, herbaceous plants, this change in habit detracts somewhat from the charm of the plant, which is more appealing as a graceful shrub.

But of all the forms of hardy Fuchsias, few are more interesting and useful than F. macrostemma var. gracilis and F. Riccartonii, two of the oldest sorts grown, the former having been raised in the Edinburgh Botanic Garden from seeds sent from Mexico in 1822, and the latter appearing a few years later in Riccarton Gardens, near Edinburgh.

There seems to be considerable confusion existing between these two plants, and this is probably due to the fact that they have several characters in common. Both plants have small, pendant flowers with oblong, pointed, scarlet sepals considerably longer than the deep violet petals; the stamens and styles are very long; the leaves small, opposite or whorled, and slightly denticulated, but here the similarity ends.

F. m. var. gracilis is much more graceful in habit and produces elongated, arching branches of flowers, whereas the branches of F. Riccartonii are much stiffer, the leaves shorter, the flowers larger and more open, and the young shoots more decidedly tinted red.

Both do particularly well near the seaside, but are good inland; both flower in great profusion, and under favourable conditions both make handsome bushes of high decorative value. *A.M.W.*

AESCULUS PAVIA.

A native of the southern United States, Aesculus Pavia, the Red Buckeye, is seldom seen in gardens in this country, although it is sufficiently attractive to merit inclusion in shrub collections, and makes an attractive specimen shrub or small tree for planting on lawns or in other prominent positions. For, although not so striking as some of the hybrid, red-flowered Horse Chestnuts, it is yet very beautiful when in blossom—during early June—and it is of compact habit, while it never attains large dimensions; as a shrub it will grow to twelve feet in height, but it is most attractive as a standard, for which purpose it is usually grafted upon another species. Grown in such a manner, it forms a compact, rounded or pyramidal head, its lower branches being quite pendulous.

Its leaves are lighter than those of the common Horse Chestnut, and are composed of five narrow, obovate or oblong leaflets which are bright green and glossy on the upper surface, and lightly furnished with down beneath, the margins being irregularly and sharply toothed.

This season, A. Pavia flowered very freely and made a very charming picture for, although the blooms never open out widely, they are so richly coloured as to attract the eye at some distance, and are borne in panicles five or six inches in length. The individual flowers are about one-and-a-half inch long, and are slender, the four petals, which have glandular margins, never expanding fully, although they open wide enough to disclose the yellow shaded throat, which tones with the rich red of the corolla.

A. Pavia, known also as Pavia rubra and Aesculus humilis (it was figured in the *Botanical Register*, t. 1,018, under the latter name), and in the tree state sometimes referred to as Pavia pendula, owing to its drooping lower branches, would appear to require no special soil conditions, and as it came through last winter unscathed, it may reasonably be classed as quite hardy.

DIERVILLA FLORIDA VAR. FOLIIS PURPUREA.

When visiting the Royal Botanic Gardens, Kew, early in June, a shrub which appealed specially to me on account of its exceptional freedom of blossoming and rich colouring was the above variety of Diervilla florida; when grouped in a bed by itself it makes a grand display. It would appear to be not so tall as the type, and is rather smaller in both flower and foliage, while it is of spreading habit, its branches not being so erect and arching as those of D. florida proper.

As stated, D. f. var. foliis purpurea is very free-flowering, for its growths were wreathed with flowers, which are rosy-purple on the outside and paler within, and combine well with the dark green, purplish edged and shaded foliage. This subject should be ideal for the rock garden of moderate size, or for the front of the shrub border.

Another striking variety of this popular flowering shrub is that with variegated foliage, *i.e.*, D. f. var. variegata. This variety has deep rose-coloured flowers and bright green leaves edged with yellow. There is a dwarf form of it known as nana, with pale pink flowers and creamy-white edged leaves. *M. W.*

ROSE GARDEN.

ROSE LADY WATERLOW ASSOCIATED WITH IRIS FLORENTINA.

The accompanying illustration (Fig. 30) depicts a very effective method of planting a bank, as practised in a Provencal garden.

Long branches of the pink Rose Lady Waterlow are pegged down, and the bank is planted with the pale heliotrope Iris florentina? The Rose, when in full flower, makes a charming groundwork for the lovely Iris, whose stately flower trusses rise above it. *C. Sandeman, La Calline, Valbonne.*

ROSA RUGOSA VAR. REPENS.

I was extremely pleased to learn of an old Rose, which I remember seeing about the time it was put into commerce in 1903, by Messrs. George Paul and Son, namely, R. rugosa repens alba (see p. 27). This was a drooping bush about three feet high, in my recollection. Visiting the nursery again in 1916, I found that the same bush, in the same place, had covered an area something like ninety-six feet in circumference.

R. rugosa var. repens is described as of weeping habit in at least two modern catalogues. In an official catalogue of the National Rose Society it is described as "creeping, weeping standard." The larger, original bush was allowed to grow naturally, and sprawled over the ground with its stout, tortuous stems, which sent up more or less erect flowering branches with a wealth of single white blossoms. I have also seen a smaller, sprawling bush, in a suburban public park.

It would appear that this same Rose has reached America, for Alfred Rehder, in his *Manual of Cultivated Trees and Shrubs* (1927), describes it as R. rugosa × arvensis, a procumbent shrub with large, white flowers in corymbs. He quotes Paul's name for it, but renames it R. Paulii, Rehd. They are fond of giving botanical names to garden plants in America; besides, it could not be considered a variety of R. rugosa from a botanical point of view, if it is a hybrid.

I do not know the origin of R. rugosa repens rosea. If it is of the same habit as the original, it could easily be a colour sport. The white one is certainly a fine plant for covering banks.

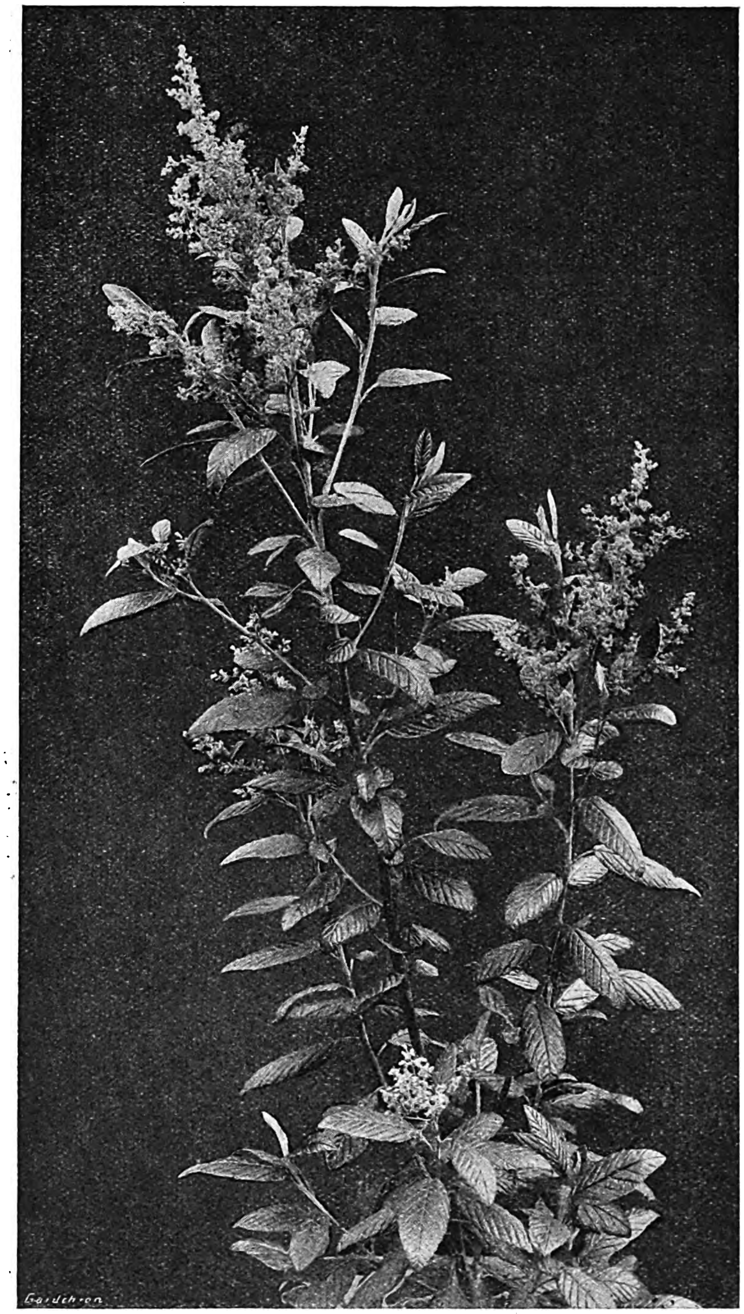

FIG. 31.—POMADERRIS APETALA.
(see p. 69.)

ROSA CALOCARPA.

In nursery catalogues the above Rose is listed as a variety of R. rugosa and described as bright rose, succeeded by rich scarlet fruits. This is the hybrid (R. rugosa × chinensis indica) which originated before 1891, yet it is not so common as one might expect. The R. rugosa parentage is quite obvious, but the leaves are smaller and almost smooth (not wrinkled). The stems, flower stalks, fruit and calyx are less bristly than is R. rugosa. This I have seen from Woburn, the Duke of Bedford's garden, and the flowers are quite vivid in colour, and single. *J. F.*

ALPINE GARDEN.

GENTIANA DECUMBENS.

It is difficult to understand why the late Reginald Farrer was so averse to this Gentian, dismissing it as of "ugly rankness," and as suitable for only "the coarsest parts of the garden" (*The English Rock Garden*). Surely such condemnation is unwarranted. True, if relegated to the rough life suggested, it will become rank and unattractive, producing its naturally ample foliage in excess, and at the expense of its blossoms; but given a suitable position, in practically full sunshine, and in deep, loamy soil, it will prove very attractive, and produce its blossoms profusely from mid-summer onwards.

Under such conditions, G. decumbens forms a close clump of long, glossy, rich green leaves, from among which will be produced, in early July, masses of rather stout, leafy stems, semi-erect, or nearly prostrate, and in the axils of the leaves will appear clusters of rich blue—with just the slightest tinge of purple—flowers, these wreathing the stems for eight inches or so, and leading up to a large, terminal cluster.

Climatic conditions would appear to exercise a marked effect upon the flowering of this Gentian, which is, incidentally, a good perennial, for in a dry season like the present it is flowering with almost unseemly abandon, much more profusely than is usual,—although when treated with respect, it is never niggardly—and at the present time it forms one of the brightest patches in the rock garden. *W.*

MYOSOTIS SPATHULATA.

A very small Forget-me-not grown under the above name possesses a quiet beauty of its own, and is certainly deserving of a place in the choicest collections of alpine plants. The compressed cushions are starred with a multitude of milky-white blossoms, and a colony of the little hummocks is quite an intriguing feature. The plant enjoys a gritty soil, but will not submit to drought, and it should be surrounded with chips or half buried pieces of sandstone. It is a very charming subject for the alpine house if grown in a small pan and arranged with a few pieces of stone about it.

M. caespitosa var. Rehsteineri is another charming sort deserving of wider cultivation. In a cool, moist corner the dense mats of foliage will be liberally covered, in April and May, with rich, pure blue flowers. It thrives and spreads rapidly in a genial situation, persistently hugging the ground and providing a delightful foil to the rarer Snowdrops, Crocuses and other choice early bulbs. *Ralph E. Arnold.*

CAMPANULA KEWENSIS.

Many are the gems among the Campanulas which delight the cultivator of alpines, and he is always glad to know of fresh arrivals which may await his appreciation. The great influx of new plants from China and Tibet has to some extent retarded the advance of others, and hence the charming hybrid Campanula kewensis has been rather slow in attaining much popularity. Nor is it as yet very plentiful in nurseries, although when catalogued it is quite an inexpensive plant. Folks pay much higher prices for far inferior subjects because they are introduced under higher recommendations. I have no record of the date of origin of C. kewensis, and conclude that it has probably been sent out within the last ten years.

Its parentage is stated to be between two rather "difficult" Campanulas in the eyes of many alpinists—C. arvatica and C. excisa—but it is not a difficult subject. I am growing it in a moraine, mulched with whinstone chips, and it is apparently very happy there. This is the position recommended for it by some growers, and it is wise to adopt it with a first plant at any rate.

C. kewensis grows about three inches high, and has neat, light green foliage and pretty upright bells of a lilac tone, open and highly attractive. It is free-growing under favourable conditions and soon lends itself to propagation by division or cuttings.

DIANTHUS CAESIUS VAR. ARVERNENSIS.

Our native Dianthus caesius, the Cheddar Pink, loses nothing in comparison with its sister flowers from other lands, although there are inferior and poorly-coloured forms among the seedlings so frequently sold, and even among the wildings of its native district. In association, possibly, with other Pinks it has given some curiously little dwarf and inferior forms, such as the writer has seen in the crevices between stone pavements; so poor, indeed, were they that it was difficult to trace a family resemblance to the best varieties of D. caesius.

D. suavis, to which some accord specific rank, is hardly distinguishable from D. caesius, but D. c. var. arvernensis, a geographical form, is quite distinct. It may be described as a miniature D. caesius, forming close-growing tufts of leaves of a grey-green, which, in May and June, are almost entirely obscured by the hosts of charming little flowers of a bright rose-pink, on stems two or three inches high. It is growing here in the rock garden on a flat ledge and in a compost of loam, a little leaf-soil and some sand and grit. It is truly an exquisite little Dianthus, worthy of being cultivated in the most exclusive collection of alpine plants.

SEDUM ALBUM VAR. MURALE.

Our most sincere thanks are due to Mr. R. Lloyd Praeger for his admirable synopsis of the genus Sedum in the *Journal* of the Royal Horticultural Society, Vol. XLVI, 1920-21. It is a masterly contribution, and should be in the hands of everyone interested in the genus. It clears up many points which have puzzled growers. One of these has been the true name of a very attractive Sedum, which has been grown in gardens, sometimes as C. turgidum, and sometimes simply as S. murale. According to Mr. Lloyd Praeger, it is only a form of S. album, a very common species, and is named by that author as S. album var. murale.

One cannot dispute the decision of such an eminent authority, but from a garden point of view, C. album var. murale is a very distinct plant, much superior for garden purposes to any other form of S. album. Its distinctive features are that its leaves, stems and sepals are purple, and its flowers pinkish instead of white. Otherwise it differs little from the type but does not appear to be so aggressive. Mr. Lloyd Praeger states that its origin is unknown to him, and tells us that it is "a very useful plant for the rock garden." This it certainly is, and it makes a good wall plant also. I have a large number of plants of it here, and was surprised to find that a leading alpine grower in the trade did not know its name, and that several amateurs could not identify it either.

GENTIANA SEPTEMFIDA.

A well-known writer on flowers has justly stated that Gentiana septemfida is a "friend of man," in alluding to its ease of culture and its great beauty. Even in a genus comprising so many delightful plants, G. septemfida takes a worthy place and cannot well be omitted from any garden laying claim to the possession of a representation of the best hardy flowers. That it is as easy to cultivate in the border as in the rock garden is a strong point in its favour, as there are many who cannot congratulate themselves on the possession of even a small rock garden, let alone a large one. I am impelled to write this note after seeing a number of good plants in the front of borders of hardy flowers in a delightful garden I visited the other day. These plants were pictures of health and beauty, with their oval, pointed leaves and heads of glorious blue flowers, giving evidence of the suitability of the garden for their welfare. The garden in question is splendidly cultivated and no doubt the Gentians profited by the liberal supplies of old manure which are supplied to the borders alternately. The soil is not naturally a good one, with a large proportion of granite sand and grit in it, and all plants need to be well cared for to obtain the successful results shown. Loam and peat are recommended as a suitable compost for this glorious Gentian, but the peat may be omitted, if not obtainable, while a little old manure well below this fine plant will afford much assistance. *S. Arnott.*

HARDY FLOWER BORDER.

CORONILLA ELEGANS.

The genus Coronilla is not a very extensive one, and not many of its members are hardy in our climate, but the subject of this note, C. elegans, is a little-known plant which is worth a place in herbaceous borders.

A native of Serbia, it was distributed from the Belgrade Botanic Gardens some twenty years ago, but although it is of very easy cultivation and is readily propagated both by division and by means of seeds, which it produces freely, it is still a relatively rare plant.

Of elegant habit, it is very distinct and has smaller flowers than the better-known C. varia, resembling rather those of an Orobus than those of a Coronilla. They are freely produced in umbels on long stalks produced from the axil of every leaf, and maintain a display from June until August, their bright rose colour giving them an attractive appearance. *A. M. W.*

LUPINUS POLYPHYLLUS VAR. MOERHEIMII, AND OTHERS.

It was with pleasure that I read the note by *W.* in your issue of June 29, p. 478, and I cordially agree with what your contributor states regarding the merits of L. p. var. Moerheimii. It is indeed a very fine variety which I have grown for years with ever-increasing pleasure. Another grand Lupin, which was raised by the same firm, Messrs. B. Ruys, of Dedemsvaart, is the variety Princess Juliana. It is dwarfer than the variety Moerheimii, and gives very shapely spikes of light pink and white flowers. It is universally admired in my garden.

Another herbaceous Lupin worth bearing in mind is the variety Lavender Bee, sent out by the noted firm of Messrs. Bees, Ltd. It is of good habit, rather taller than var. Moerheimii, but not much, and produces long, handsome, many-flowered spikes of flowers of lavender and white.

Still taller, also, and with very fine spikes, is the one named Sunbeam, raised by Messrs. Oliver and Hunter in 1924. It has long spikes of pale salmon, and is a very effective border plant. These are not mentioned with any desire to depreciate the magnificent varieties raised by Mr. G. R. Downer and others, but to bring before readers a few from other sorts which are also worthy of inclusion in their gardens. *S. Arnott.*

BULB GARDEN.

ALLIUM NARCISSIFLORUM.

The late Reginald Farrer, in his invaluable work, *The English Rock Garden*, placed this species at the head of the list, describing it as the glory of its race, and undoubtedly it deserves this honour for, although several other species approach it closely in floral grace and colouring, yet none of them possesses the complete charm of A. narcissiflorum, which combines attractiveness of foliage with freedom and ampleness of blossom, and unique colouring; its one drawback is its unwholesome odour—which can be forgiven in an Allium.

A. narcissiflorum is well deserving of a warm, sunny nook on the rock garden in moderately light and well-drained, loamy soil, or in the moraine. It forms a close mass of narrow, grey foliage, among which, during July, arise numerous stout stems to a height of nine or ten inches, each crowned with a drooping cluster of short-pedicelled flowers, varying from a few to six or eight in number. And these flowers are of exquisite form, large, and bright vinous-red or rosy-purple in colour, covered on the exterior with a slight "bloom."

A. narcissiflorum hails from the European Alps and is, apparently, widely distributed, being found in stony screes at high altitudes. Despite this, it responds well to garden culture, asking no special favours in the way of after care, and caring for itself when once planted in a congenial position. *M. W.*

LILIUM PHILADELPHICUM.

Strolling over dryish ground on the outskirts of a wood in early July, I was attracted by several glowing masses of orange-red colour which lit up the recesses of lightly shaded situations. Closer investigation proved these to be the upright flowers of the Wood Lily—Lilium philadelphicum—a species which is common from New England to Ontario and southward to North Carolina. It is a glorious species but, unfortunately (according to Bailey), it does not do so well under cultivation as in the wild.

The stems are from one foot to three feet in length, and bear linear-lanceolate leaves, usually in whorls of from three to eight, but scattered leaves sometimes occur between the whorls. The lower part of the stems is usually devoid of foliage. The apex of the stem terminates in from one to three, or occasionally more, flowers, arranged in umbellate fashion. They are held stiffly erect on pedicels nearly as long as the corolla segments. Each flower is three or four inches in diameter, with the sepals two-and-a-half to three inches long and narrowed to a claw-like base. The segments are quite smooth, the inside being of a rich orange-red hue, tinged with yellow towards the centre, and spotted with maroon or purple markings. The outer side is paler in colour and the anthers are dark red.

A variety known as L. p. var. andinum occurs further west; it is distinguished by the leaves being nearly all scattered and by having larger or more richly-coloured flowers, besides being a stronger grower.

L. philadelphicum possesses no scent, but it is exceedingly attractive in the wild state and would be equally so in the garden, where conditions favour its growth. *T. H. Everett, New York, U.S.A.*

POMADERRIS.

The accompanying photographs (Figs. 31 and 32) are of two New Zealand shrubs that are little grown in this country, viz., Pomaderris elliptica and P. apetala. The genus Pomaderris consists of about twenty species, whose distribution is confined to the Australasian region. Five are found in the northern part of New Zealand, and of these, three are found in Australia also.

As might be expected from their natural habitat, these plants are not hardy in this country; but they are not difficult to grow in a cool greenhouse.

P. elliptica (Fig. 32), called by the Maoris Kumarahou, is a small shrub which may reach four or five feet high, and in New Zealand is a beautiful plant when in full flower. If raised from seeds it may be expected to flower in March of its third year, when about twelve to eighteen inches high. The small, bright yellow flowers, in close clusters, give it a very gay appearance, but its rather dull, greyish foliage, and its awkward habit of growth, prevent it from taking a very high place among ornamental shrubs.

P. apetala (Fig. 31), known to the natives of New Zealand as the Tainui, is a taller and more shapely shrub, which reaches fifteen feet in its native land. In contradistinction to the Kumarahou the foliage of this species is admirable. The leaves are two to four inches long, of a deep but very bright green, and often margined with a creamy variegation. The under surface of the leaf is covered with hairs which are white, except on the prominent ribs, where they are reddish-brown. These hairs well repay examination with a strong lens; for they are then seen to consist of a beautiful series of stars and have somewhat the appearance of a bed of Sea Anemones in miniature.

The Tainui is well worth growing for its foliage, and early in its third year it throws up large, terminal trusses of bloom. But those who expect a glorious reproduction of the brilliant flowers of the Kumarahou will be sadly disappointed when the flowers expand towards the end of April. As the name implies, the flowers have no petals, and the result is an unconvincing mass of dull yellowish-green.

New Zealand plants are ridiculously prone to cross-fertilisation, but, so far, I have not heard of a hybrid between these two species. Could one be obtained which would add to the splendid foliage and the magnificent truss of the Tainui, the brilliant individual flowers of the Kumarahou, it would be glorious indeed.

With regard to P. apetala, the Maoris have an interesting tradition, owing to which they regard this plant with an almost religious veneration. Somewhere about the twelfth century, the Maoris made their great voyage from Hawaiki to take possession of the then uninhabited islands now known as New Zealand. This voyage would be one of nearly 4,000 miles, but for the first 3,000 miles there would be many Islands at which they could stop on the way. This great expedition was made in a fleet of sea-going canoes; each of these consisted of a pair of large dug-out canoes hacked from the trunks of single trees. Each pair was joined by a deck bridging over the space between them; and on this deck would be small deck-houses. Craft of this kind would hardly meet the requirements of the Board of Trade for an ocean journey, but the Maoris were troubled with no regulations.

Now, for the purpose of running these heavy and unwieldy canoes up the shore when landing, each carried a number of rollers made of suitable sections of round-stemmed trees and shrubs. One of the members of this remarkable fleet was named the Tainui, and the rollers carried on this ship were stated to have been sections of the stems of the shrub now known as Pomaderris apetala. When the Tainui reached New Zealand and had been run up the shore, one of these rollers was driven into the soil to be used as a mooring post. Miraculous to relate, this post took root, grew into a flourishing shrub, and became the ancestor of all the shrubs of this kind in New Zealand! Consequently, it was ever after known as Tainui.

So firmly was this tradition held that it was accepted by the early botanists, and the plant was at one time known as Pomaderris Tainui. It is a shame to discredit so picturesque, although unlikely, a story; but later investigations show that, besides the improbability of this thick trunk taking root after its lengthy voyage, there are the following objections against accepting it: (a) No plant of this species is known in any of the Polynesian Islands, or in any of the islands which they touched on the way; (b) in the neighbourhood of the place at which the canoe Tainui is known to have landed in New Zealand this species has not been found, and (c) this species, like 368 other members of the New Zealand flora, is common to both New Zealand and Australia, and Australia was certainly not touched by the canoe Tainui. *A. H. Williams.*

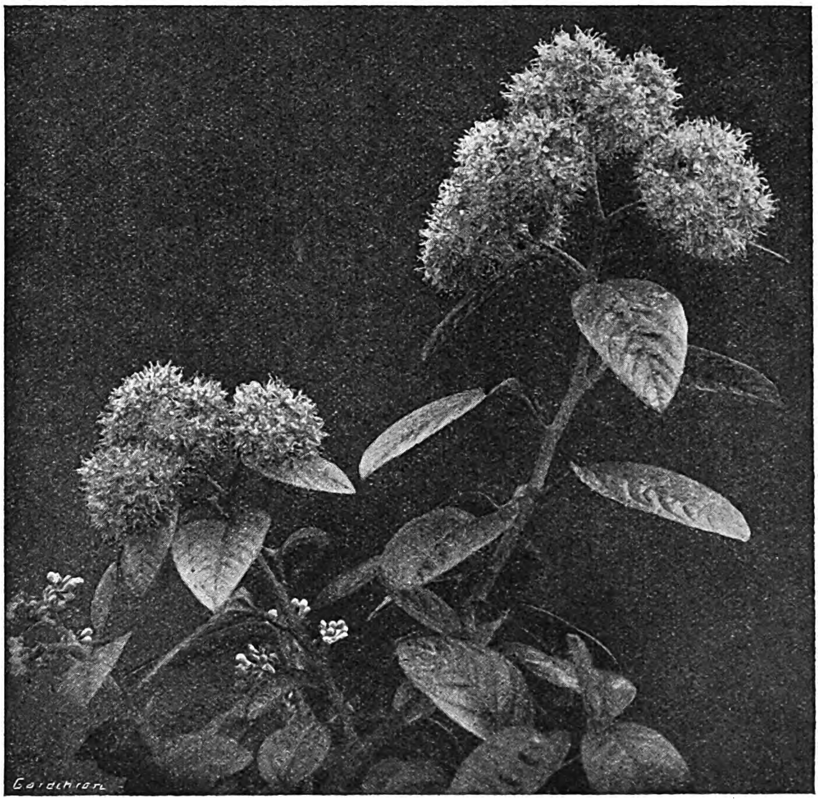

FIG. 32.—POMADERRIS ELLIPTICA.

HARDY FERNERY.

ADIANTUM PEDATUM.

Two species of the genus Adiantum occur in temperate North America, and of these the plant under notice is by far the more common, the other being A. Capillus-veneris, which also occurs in Europe (including Great Britain) and in this country is limited to more southern latitudes than A. pedatum.

The slender, creeping rootstock of A. pedatum is chaffy, and roots along its whole length, sending up dark, polished, chestnut-brown stipes which are dichotomously forked at the summit, the stipes being up to two feet in length. In outline, the frond is obliquely orbicular, the pinnae of which it is composed arising from the upper sides of the two main branches of the stipe, and are disposed in radiate manner. The pinnules are arranged alternately, almost in herring-bone style They are almost oblong with the exception of the terminal one, which is fan-shaped. They are very short-stalked, with the lower margin entire and slightly curved. The inner margin is also entire, while the upper and outer margins are cleft and lobed and bear the linear-oblong sori.

Adiantum pedatum is found in rich, moist woods, being at its best in June and July. Its delicate green colouring and graceful appearance render it an object of admiration when seen in a shady nook in its native home, and not less beautiful is this worthy Fern when given a congenial place in the hardy Fernery, wild garden, or rock garden. *T. H. Everett, New York, U.S.A.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XXVI.—THE ALPS AT LAST.

OUR one desire now was to reach the alpine region. Our camp stood on the lip of a gulf, whose mouth narrowed gradually to the deep ravine below Tablekon; at its head, this gulf broadened out into a funnel, bounded by the two arms of Kaso, which met at an obtuse angle below the final peak. The whole funnel head was jammed with forest, and its steep sides were striped with gullies which drained the semi-circular rim and met the apex below to form the Tablekon torrent. Thus we looked straight across the funnel to Kaso, but to reach the mountain we had to go right round the outer rim, following the ridge. Had it been a straightforward climb, we could have reached the alpine region in an hour, from our camp; but the ups and downs of the ridge added miles to the distance, besides robbing us of height, and it turned out to be a good three hours' march to a point on the ridge where we stood clear of the last stunted Larch and Fir trees.

The monsoon had not yet definitely broken, so we decided to celebrate June 4 by a big climb—Buttercup being an old Etonian. We breakfasted at 6 a.m., and by 7.30 were on the way. No time was wasted on the first part of the ascent, and we soon reached the rocks, the next landmark being Buttercup's well. Then came the Water Cliff, whence our supply of drinking water was drawn, reached in thirty-five minutes, followed by the Look Out, Primula Rock, and Isopyrum Cliff. Passing up Gloomy Glen, we reached Calostrotum Ridge, hoping for a view ahead; but by this time clouds had blacked out everything. The open ridge here was covered mainly with scrub Birch and Rhododendrons, among the latter being the pink 'Barbatum,' tawny 'Roylei,' scarlet 'Thomsoni' called 'Coals of Fire II,' gory 'Sanguineum' and plum-coloured 'Brachyanthum.' The gory 'Sanguineum' has very dusky flowers, the colour of dried blood, but there was another rarer species mixed up with it, having much brighter scarlet flowers, and a buff-coloured distemper on the under leaf surface. Mixed up with the Rhododendrons were bushes of Viburnum and an undergrowth of small-leafed Ilex.

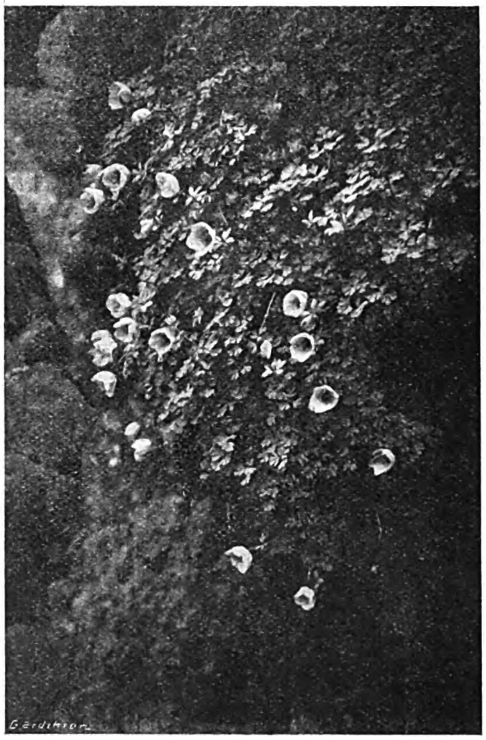

FIG. 33.—ISOPYRUM GRANDIFLORUM, ON THE CLIFF FACE: 11,000 feet altitude.

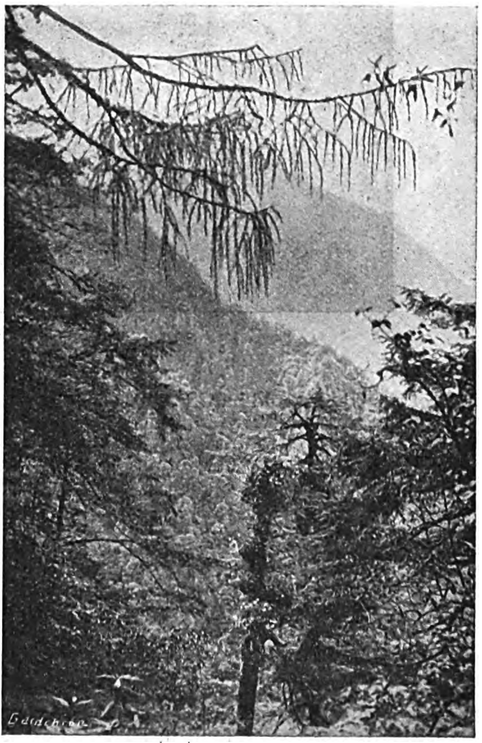

FIG. 34.—CONIFER FOREST AND EPIPHYTIC RHODODENDRONS: 11,000 feet altitude.

A sharp ascent now brought us as it seemed to the verge of the alpine zone, as we tramped over a nodding sea of purple 'Saluenense' Rhododendrons; but all that followed was a long descent through Abies forest, and we tramped on without noticing any material change in the vegetation. Presently, however, the ridge erupted in an outcrop of bare rock, and one side was cut away in a cliff; here we met with our first Primula, a nice-looking yellow-flowered 'Nivalis.' I write 'nice-looking' advisedly; there was nothing at all startling about it. The leaves are strap-shaped, rather leathery, dark green above, silvered beneath; the circular corolla is a good, douce yellow, paler in the centre owing to meal, about an inch in diameter; height twelve to fifteen inches, with three to six flowers in a head. I fancy it is a new species; nor does it look exacting to grow.

Half-a-mile further on we came to another outbreak of alpineness, where grew plants of the 'Denticulata' Primula and Cassiope, and also a pretty, dwarf, bearded Iris. This last is a rhizomatous species and grows in bulky clumps on the steep, alpine turf slopes, but although full of flower, the clumps rarely ripen more than two or three capsules, these being flush with the ground. The flowers, which have the falls prettily mottled and skeined with violet and white, are faintly fragrant. However, this is probably the same species as the one collected in the Seinghku valley in 1926, although that had distinctly purple flowers.

Another ascent brought us at last within sight of the open ridge, and traversing round a bump covered with scrub Rhododendrons, among which we noticed a glorious 'Haematodes,' aflame with big, crimson bells, we reached the alpine zone, and the first patches of snow.

On our right, the ridge dropped very steeply into the funnel, the upper part of which was filled with scrub Rhododendrons; on our left, a gentler slope led down into a series of shallow alpine valleys, mostly filled with snow. Two Rhododendrons instantly attracted our attention. The first was a sulphur-yellow 'Souliei' of the type commonly met with along the rainy alpine ranges from the Tsangpo gorge in Tibet, eastwards to the Burma-Yunnan frontier. 'Yellow Peril,' collected on the Doshong La in 1924, and the sulphur 'Souliei' from the Seinghku valley, 1926, were both of this type, whose chief charm lies in its new foliage which, by autumn, has turned a startling verdigris-green. This 'Souliei' grew all over the place, forming solid seas of yellow on north slopes between the snow channels.

The other conspicuous Rhododendron species was found growing only on the south rim of the funnel, where it formed impenetrable thickets of gnarled and twisted branches. It had small, oval, thick leaves, dark matt-green above, and covered below with what looked like a layer of wet wash-leather. The flowers, borne loosely in trusses of three to six, varied; they were pink in bud, but opened more or less cream, although often retaining a pink glow, and liberally sprinkled with maroon-coloured spots. Both foliage and flowers suggested all I could recollect of R. lanatum, and I am not prepared to deny the possibility of it being that species, until I have had an opportunity to compare them. On the face of it, perhaps, it is unlikely that a Sikkim species should be found so far east; but I have already pointed out that the distribution of individual species, both of Rhododendron and Primula, is wider than was formerly supposed, along narrow belts to north or south of the line of high peaks. The difficulty is, of course, to lay down the exact direction of that line of high peaks! But we were in no difficulty as to how we were situated with regard to it in 1928!

Proceeding along the narrow crest of the ridge over carpets of dwarf and scrub Rhododendrons, chiefly 'Sanguineum' and 'Saluenense' with here and there a mat of 'Rock Rose' (Fig. 35), we halted at 11.30 to eat our lunch, an operation we were forced to hurry through as we found that, meanwhile, the sand flies were lunching off us. The weather was fine, at least, no rain fell, but there was a cold breeze urging the mist up the funnel below us; every now and again, although the clouds would break, and through the rifts, we would get tantalising peeps. We found that we were close to the great north snowfield of Kaso, and evidently it would be some time before all this snow melted and the summer flowers bloomed. I went a little further up the ridge and found 'Scarlet Runner' (Rhododendron repens!) running over the rock ledges in blood-red rivulets, and other dwarf species not yet in bloom; and then slid down a long snow slope into one of the valleys on the north face. The first thing that took my eye here was Primula calthifolia. The leaves were not developed, but the pale yellow flowers were opening bravely on their reddened stems in the bleak desolation. The plant grew in hundreds on the sodden turf and mud slopes on the edge of the snow drifts, where scarcely a blade of green showed, and much which before was obscure now became plain.

---

Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; March 2, 16, 30; April 13, 27; May 18, 25; and June 1, 15 and 29, Vol. LXXXV; July 13, 1929.

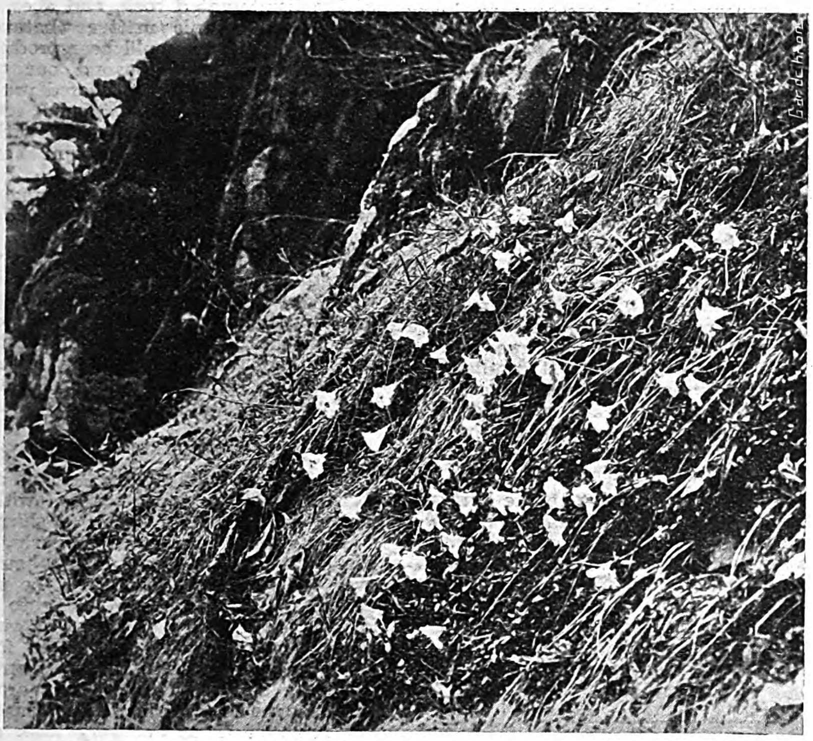

FIG. 35.—A PATCH OF RHODODENDRON ROCK ROSE.

In June, 1926, I found a single clump of a yellow-flowered Primula up a gulley, in the Seinghku valley, which was subsequently named P. calthifolia by Professor Wright Smith, who placed it in the section Petiolaris. So rare was the plant that I collected only a single specimen, intending to get seeds from the two or three specimens remaining. In October, 1926, I returned to the gulley, and at the spot where I had collected P. calthifolia, I found half-a-dozen plants of a Primula in seed, which I naturally supposed was the yellow-flowered species collected in June. It was an obvious 'Nivalis,' with long, strap-shaped leaves, and a long, sausage-shaped capsule, and I was rather surprised when Professor Wright Smith assigned P. calthifolia to section Petiolaris, contending that it was really a 'Nivalis.' Unfortunately, the 'Nivalis' collected in October was also rare, and although I got some seeds of it, I did not preserve a specimen.

There the matter rested until June, 1928. When I saw P. calthifolia again, I recognised it at once, and when it had finished flowering and the coarse leaves had developed, I saw my mistake. The two plants collected in that Seinghku gulley, at almost the same spot, in June and October, 1926, were not the same species, and, therefore, the numbers of P. calthifolia (type) and the seeds assigned to it, do not conform. There were no seeds of P. calthifolia (K.W. 6,897) collected in 1926; conversely, Primula *seeds* K.W. 6,897 were not of P. calthifolia, but a 'Nivalis' species, of which there is no corresponding herbarium specimen. Professor Wright Smith was perfectly correct in assigning P. calthifolia to the Petiolaris section, as my present herbarium material will amply confirm.

On the north slopes, a big fat-headed Rheum was bursting through the mud, Ferns were unwinding their springs, Monkshoods peeping, and other herbs of the alpine meadow preparing to display themselves; the only other Primula in flower here was P. vernicosa, but I noticed P. capitata on a rock, with the white-flowered Androsace geranifolia. From every cliff hung shivering bunches of the dark-flowered Isopyrum grandiflorum (Fig. 33). On the way back it rained, and we reached camp wet and cold after ten hours climbing, with a fair amount of alpine booty. *F. Kingdon Ward.*

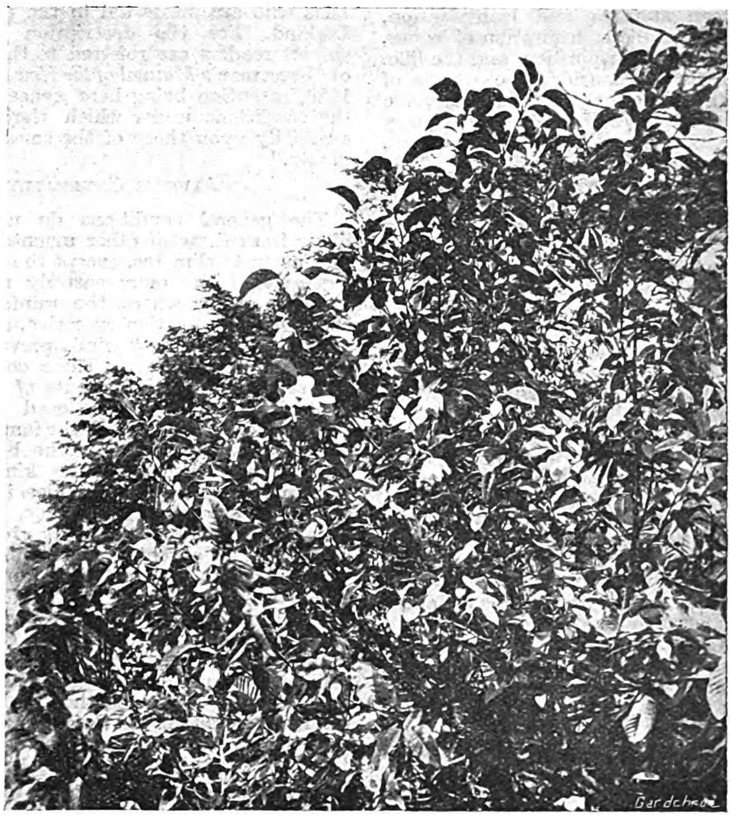

FIG. 36.—MAGNOLIA GLOBOSA IN FLOWER: 9,000 feet altitude.

PROBLEMS OF PLANT LIFE.*

V.—THE SIGNIFICANCE OF WILTING.

WHAT is meant when we say that a plant has wilted? The dictionaries often omit the word, and rarely give a satisfactory definition. We usually think of it as synonymous with withering, fading and decaying, and regard it as a bad sign suggesting drought, malnutrition or disease. But to wilt also means to droop, and drooping may, in reality, be a sign of health and ready response to the conditions in which the plant is found. We may find an analogy in the human system. One hears a good deal to-day about blood pressure. It may be too high or too low, and in either of these cases there may be danger. There are times, however, when the pressure varies in response to circumstances, and this is a sign of health. It is so with the plant which droops when the soil is dry and revives on the application of moisture. Active and passive states and conditions are characterised by a suitable response. In the case of plants, wilting or drooping usually means loss of turgidity due to the water content being low. But from a physiological point of view, this act of wilting may be good, and our present object is to deal with this recent problem in plant life from that standpoint. Our contention is that under certain conditions wilting may be a sign of health, and play an important part in the economy of plant life. Until quite recent years it was assumed that the plant drooped only for want of water, and that the remedy was either to give it a fresh supply, or, if this were impossible, to allow the process of wilting to go on to the bitter end. Even yet our knowledge of the subject is very imperfect. This is, in part, due to the fact that until well into the present century everyone looked on wilting pathologically, and did not observe that it is frequently quite a normal mode of behaviour, a sign of vigorous health, and a spontaneous action of great economic significance in the life of the plant.

Wilting may be defined as a flaccid condition, a loss of turgidity, resulting in an altered appearance of the plant, due to its drooping or modifying the position of its parts. The cause usually is to be found in the low water content or readjustment of the water pressure in response to the environment. It may be transient or permanent, and it may be stated as a general rule that, while permanent wilting is pathological, transient wilting is a sign of health and a spontaneous safeguard against undue evaporation and other exhausting or debilitating processes.

---

* Previous studies appeared in our issues of April 13 (p. 279-80), June 15 (p. 446-7), Vol. LXXXV, July 13, (p. 30), and July 20 (p. 50).

Significance has been given to this subject by the fact that the culture of plants often has to be carried out under dry conditions. It is important, therefore, to learn how plants in a state of nature meet their needs in circumstances such as these. The study of desert plants, and such vegetable forms as are able to survive long periods of drought, has taught us that many devices have been adopted, and careful observation has shown that what is known as wilting is one of these. Although the subject has only been studied systematically and scientifically during the present century, the bibliography is already extensive, and the specialist need have no difficulty in finding many excellent memoirs and text-books for his guidance. Viewing the subject historically, we may note that at the close of the last century the study of transpiration received a good deal of attention both at home and abroad. Piche, in 1872, described in French an instrument for measuring evaporation. In 1887, Henslow made a contribution to the study of the relative effects of different parts of the solar spectrum on the transpiration of plants, and Areschoug, about the same time, wrote concerning the influence of climate on the organisation of plants, especially on leaf structure. These and similar researches led to a re-investigation of the stomata—their position, number, structure and action under various stimulating agencies; but the bulk of the work on wilting has been done within the last two decades. The new century has brought new points of view. Thus we find F. Darwin, so long ago as 1898, publishing some observations on stomata, while in 1914-16, he takes up the subject afresh, and writes on the relation between stomata and transpiration, the effect of light on the transpiration of leaves, methods of studying transpiration, and the like.

When we come to consider the causes of wilting in plants we find that they vary. In some instances, even although the soil is sufficiently moist, wilting is seen to follow when a hot, dry wind is blowing. This may be due chiefly to two causes. Either the root system is not sufficiently developed to convey the necessary water to the leaves and thus maintain their turgidity, or the plant is itself unable to conduct the water upwards owing to the nature of the tissues and the shape of the leaves. This is rendered clear by the fact that the parts which first show signs of wilting are those which are furthest removed from the water supply, such as the tips of linear leaves and the margins of the broader kinds. Such wilting, however, is usually temporary. Permanent wilting is more frequently due to soil drought. If a plant cannot obtain water from the ground, or if its supply is unequal to that which is lost by transpiration, wilting ensues. It sometimes happens, however, that both causes are in operation at the same time, and it is under these circumstances that the test is most severe. In dry weather a plant with abundant roots and a good water supply may wilt without suffering, but plants which live in dry soil must have special means of protecting themselves.

Among the means which nature has devised to meet this emergency, three may be specially named. Some plants are able to check the loss of water through transpiration by such means as a deposit of a waxy film over the leaves, a thickened cuticle, or hairs which reflect the light and so reduce the rate of absorption of solar radiation. In the next case, we find succulent plants which have the ability to lay up a store of water, after the fashion of the camel, and thus withstand a long continued drought. Roots, tubers and underground organs so well as leaves and stems,may be utilised as tanks for this purpose. And this leads us to the third and most important means of all, viz., the development of a system which is capable of withstanding the effects of drought, such as one finds in certain Ferns, Lichens, Mosses and allied plants.

To fully understand the bearing of wilting on plant economy it is necessary to know something about the stomata, usually to be found in the under surface of the leaves. These vary greatly in number, size, situation and responsiveness to atmospheric and other influences; and much that is new and instructive has been learned by their intensive study during recent years. Experiment shows that the phenomena of transpiration are extremely complex, and that it is not easy to state what are the conditions which govern those phenomena. Fundamental to all is the water supply. If this is inadequate the plant may wilt in order to reduce transpiration, just as stranded folk with a limited water supply will ration themselves. In other words, wilting is frequently a device for ekeing out the supply of moisture, and so securing a longer lease of life. It results from "an excess of loss over intake of water," the volume of the cells decreasing *pro rata* with the loss of water, and thus causing the loss of turgidity. This reacts on the stomata and reduces the rate of transpiration.

Wilting is, therefore, of value to the horticulturist in that it indicates the condition of the tissues in relation to the water content. It may be a sign of distress, showing that the soil is too dry, or the atmosphere too parching. If placed at once in moist conditions and screened from drying winds, the plant will usually soon recover; but permanent wilting may follow neglect, and this will prove its undoing. *Hilderic Friend.*

ALPINE AND SHINGLE PLANTS OF NEW ZEALAND.

The following account is designed to be of assistance to growers resident in the British Isles who are interested in the plants of New Zealand. For the description of particular species readers are referred to the last edition of Cheeseman's *Manual of the New Zealand Flora*, 1925, attention being here concentrated upon the conditions under which they grow, more especially upon those of the so-called "shingle plants."

Alpines Generally.

The general conditions do not materially differ from those of other mountainous regions in temperate climates, except to some degree in the case of the more easterly ranges of the southern Alps, where the rainfall is scanty, the degree of insolation excessive, and extremely violent, hot, parching winds prevail during the whole of the summer. These conditions have favoured the growth of plants of the mat form generally, and have produced certain quite distinctive plants, of which the famous Vegetable Sheep (Raoulia eximia) is the best known by reputation. This, with the kindred species, R. mammillaris and R. bryoides, is restricted to the drier eastern ranges. Thus, at Mt. Cook, R. eximia occurs on the spurs of the mountain itself, but is absent from the Sealey Range, which is only a mile or two distant on the west. The strong north-west winds deposit nearly all their moisture on the western ranges, and reach the eastern as very dry gales, bringing only occasional sharp showers and flurries of rain or sleet which can be of but little benefit to plant life. This must, then, be considered an essential condition for their growth, and must seriously militate against success in growing them anywhere in the British Isles.

Raoulia eximia, which may be taken as typical of the whole group, including Leucogenes grandiceps (Edelweiss), grows at the altitude of from 4,000 feet to 6,000 feet on dry rocks or rocky faces, especially where the rock is loose or more or less disintegrated. It always prefers sunny situations. The young plant usually appears on the surface of the rock, where it is more or less split, so that the roots are flattened between the two surfaces in a very remarkable manner; as it grows, it forces the rocks asunder and so makes room for its thick, woody stem. The roots run back into the looser material, which consists of the dust and small gravel of the disintegrated rock, and does, of course, contain no organic matter whatever. These edaphic conditions could be reproduced easily, but the insolation is beyond our control, so that success must be considered problematical. Other plants to which this applies are the three species of Haastia, together with Raoulia Youngii (formerly Helichrysum Youngii) and several species of Helichrysum.

Haastia recurva, a very striking and ornamental plant, grows at great altitudes, usually from about 5,000 to over 7,000 feet. It occurs on the top of ridges and among rocks where very few other plants are found. It is a large plant with very numerous roots which are not very long—not much more than one foot. These run down into a gravelly dust much mixed with small stones. It is always fully exposed to sun and wind. The other species of Haastia grow under exactly similar conditions.

The Shingle Plants.

The eastern Alps of New Zealand are characterised by steep slopes covered with detritus, which are generally called "shingle-slides." "shingle-slips," or, more properly, "screes." They extend in altitude from about 2,500 to over 6,000 feet, and represent the pure débris of the upper rocks on its way to the lower levels. They offer a habitat to a very curious assemblage of plants—unique, in fact—which are specially adapted to life in this environment. As many as twenty-five species are reckoned by Cockayne as occurring only in this formation, but some of these are very rare, and some, such as the grass, Poa sclerophylla, would not repay cultivation, except as curiosities. The rock is exclusively greywacke; the stones are always on the move; the situation is always fully exposed to both sun and wind.

The stones are naturally of all sizes, from large boulders down to mere gravel, but the average size of the stones where these plants grow best is from half-an-inch to one inch or two inches in diameter. The top layer is usually from three to four or five inches in depth, and it is very important for the grower to note that if the depth is either much more or much less than this, the plants are not found. Where the substratum lies bare, as often happens when the gradient is too steep for them to find even a temporary lodging, there are no plants of this class at all. And, on the other hand, if they collect too thickly and lie to a depth of, say, one foot, again no plants are to be found. As in the case of the alpines already noted, the dry climate is a necessary condition, and we find "shingle slides" on the more westerly mountains which seem to resemble those of the eastern in every particular, yet have no true shingle plants upon them at all.

Beneath the top layer of stones we find a damp, cold substratum of very closely compacted material to any depth. This material still consists largely of small stones and gravel, but it has a very distinct consistency, and there is always a perfectly clear line of demarcation between the loose stones on top and the more solid material beneath. It is of such hardness that it can be readily dug into with an ordinary strong stick, and offers a fair foothold for the heels of strong boots, if one should wish (or be obliged) to travel upon it. It is evident that both the top layer of loose stones and the substratum of compacted gravel are absolutely necessary conditions for the growth of these plants, but some of them are not quite so particular in these respects as others. I observe that Stellaria Roughii, for instance, frequently manages to find a footing in places where no other species is present, especially where the top layer of stones is deeper than the others can exist in.

How the Shingle Plants Grow.

Ranunculus Haastii may be considered first being one of the most interesting and distinctive of the group, and the one which, in my opinion would best repay cultivation.

This plant has a strong, thick rhizome which lies exactly on the surface of the substratum, so that the stems of the leaves are embedded in the loose stones, and are colourless for the necessary distance. The roots are very thick and very numerous and run out from the rhizome in all directions, but more especially up the hill; they tend to be more or less horizontal at first, and later run right down. The thick, cord-like roots are devoid of rootlets until they near their end. As they are very long, the rootlets are found at a distance of from one to two feet from the rhizome, and they are disposed along the last six inches or so of the root. Thus they penetrate into the wetter and colder parts of the substratum for their sustenance. A very deep supply of stony and closely compacted material would, therefore, seem to be another essential for the successful growing of this plant. It must, of course, be able to withstand a very low degree of temperature, as severe frosts are to be expected before the snow covers the shingle for the winter. The heat which it can withstand must also be very great, for the upper surface of the stones becomes exceedingly hot for long periods in the height of summer.

As is the case with all these plants of the shingle, the individuals grow far apart from one another, never forming anything like a close covering of the surface, but this fact would not seem to have any special significance for the gardener. I notice, however, that when a plant of this particular species is examined closely, it is sometimes found that two have come up together and seem to the eye to form one only. The stones are, naturally, not water-worn, and have very sharp and irregular edges; it would be as well to reproduce this condition in attempting to grow the plants, even although we cannot see that it is necessary or useful to the plant.

Stellaria Roughii, the most widely spread of all this group, is often found at the very bottom of the shingly slopes so well as very high up. As mentioned, it is able to maintain itself under more trying conditions than others of this group, so that it should not prove hard to grow. The roots run in the same manner as those of Ranunculus Haastii, mostly up hill, but they are extremely fine and difficult to extract from the ground without breaking. They are astonishingly long for the size of the plant, which is rarely so much as six inches high, and I have traced them to a distance of over three feet. Like those of the Ranunculus, they are provided with rootlets only towards the end.

Cotula atrata is another very common plant of the shingle. Its manner of growth and rooting are similar to that of the Stellaria, but the roots are not nearly so long.

Lobelia Roughii is a very small plant growing commonly at an elevation of from 3,000 to 6,000 feet. It maintains itself very well where the stones are not lying at all deeply. The roots are rather fine and less numerous than those of Ranunculus Haastii; they run out in all directions to about six or eight inches only.

Notothlaspi rosulatum, generally known as the Penwiper, is a most attractive plant with a delightful perfume, and attempts have been made both in New Zealand and in England to grow it, but, so far as I can learn, without success. It does not only grow on the shingle-slides as here described, but in similar situations, such as stony beds of mountain streams. It differs from the other plants here dealt with in that it has a single tap-root. This root is not very long, a plant about twelve inches high having a root about nine inches long, with the rootlets confined to the last three inches. It holds the ground but feebly, and easily comes away in the hand. It is very unlikely that it can be grown except under the conditions above described. As other plants which grow in its vicinity, and under similar conditions, have been quite successfully established in Sussex gardens, I think it probable that this beautiful subject may yet prove to be amenable to cultivation in England, if as near an approach as possible be made to its natural conditions. Like all the plants here mentioned, it will require all the sun that may be available. *Arnold Wall, Canterbury College, Christchurch, N.Z.*

SOME GARDENING FALLACIES, ANCIENT AND MODERN.

(*Concluded from p.* 52).

In order to avoid purely destructive criticism I would make the suggestion that much benefit would be derived from research in the matter of tools. Suggestions and criticisms should be invited from actual users, and experiments conducted with a view to finding out the best design for each tool and for each set of circumstances. It is not that the problem is difficult of solution, but that in the past it has not been regarded as of sufficient importance for organised research. But its importance is too obvious to need emphasis, and it is doubtful whether the manufacturers of horticultural tools generally are as progressive as the manufacturers of agricultural tools.

Perhaps it may not be out of place to refer to one other fallacy which seems in a singular degree to be directed against the gardener, the fallacy that a man is too old at forty. One has only to follow the advertisements to realise that the boycott of age is not imaginary. A man may be a cabinet minister, an archbishop, a doctor or a lawyer to an advanced age, but the logic that entrusts the morals, lives, and destinies of a nation to the intellects and capabilities of men of seventy and upwards, cannot entrust the care of gardens to men approaching their prime. Why? Undoubtedly the underlying reason is the fallacious argument which is similar to that of the tool makers, that a man's capacity for physical labour declines with advancing years. Like the English tool-maker, the English employer often assumes that brute strength is everything. The more soil that can be got on the spade at once the more will be shifted in a day! The younger the operator the more sustained his efforts, and so on! It may well be asked whether the success of the gardener depends wholly or even chiefly on physical strength. Surely not! There is hardly another profession where the ripe experience, which only comes with years, is of such practical advantage. A good gardener never ceases to learn, and in respect of knowledge his usefulness continually increases with age. The decline of physical vigour in a class of men following such a healthy, outdoor occupation is scarcely appreciable, and is certainly more than balanced by the added efficiency arising from wisdom and experience. The gardener of advancing years asks for nothing more than trial, and judgment by results, but he must continue to assert that pre-judgment by age alone is a fallacy.

It is not an uncommon opinion that the average woman gardener is inferior to the average man gardener, but my experience is that it is only when sheer physical strength is needed that the woman shows any inferiority. In much of the work appertaining to gardening she holds her own easily and often excels in such work as seed-sowing, disbudding, Grape-thinning and floral arrangements, while we must at least give her equal place in her ability to conceive and carry out the many phases of colour-scheme gardening so essential to our craft in these days. And it is good that the young man gardener of to-day should meet this competition, the keenness of which is likely to increase rather than decrease, for we are on the eve of labour mechanisation, and the greatest handicap to the total efficiency of the woman will be largely eliminated.

Finally, it may not be irrelevant to suggest that probably the greatest fallacy of mankind is to imagine that his fellow man is his real enemy. On the surface, this may not appear to be apposite to this article, but no race of men is brought so closely into touch with the potential destruction of pests and diseases and its relation to food production as gardeners. It is largely due to the warning of Sir W. Crookes, in the latter years of the nineteenth century, that there was danger of lack of nitrogen depressing the world's crops and causing starvation, that we may now obtain practically all the nitrogen we want direct from the atmosphere.

Many deep thinkers of the type of Sir W. Crookes believe that the next great war will be between man and the lower organisms. It would be a tragic end to man's existence if, while he is devoting his energy and knowledge to the production of engines for the destruction of his fellow man, he fails to find means of combating these organisms with sufficient energy to prevent his own destruction. *W. Auton.*

THE GENUS PRIMULA.

(*Continued from p.* 49).

PAULIANA (W. W. Sm.). Paul's P.

(Cortusoides-Geranioides).

A beautiful, robust, deciduous, perennial species of tufted habit with minutely hairy leaves six to eight inches long, with orbicular-ovate blades two to three-and-a-half inches long, heart-shaped at the base, borne on distinct, minutely hairy stalks; margins cut into about seven coarsely toothed lobes fringed with minute hairs. Flower stem nine to sixteen inches tall, slender, flexuous, covered with minute down and bearing a long, loose, one-sided raceme of twenty to thirty pale yellow blossoms with orange-coloured eyes and tubes, borne on slender stalks a quarter-of-an-inch to three-eighths-of-an-inch long. Corolla nearly flat, about three-quarters-of-an-inch across, with egg-shaped, notched lobes; tube about half-an-inch long, narrowly cylindrical, with an obscure ring in the throat. Flowers in August and September. In cultivation in 1923.

Grows in open mountain meadows and on the margins of thickets and forests, on the mountains south-east of Yungning, in south-western Szechuan, western China, at 11,000 to 12,000 feet above sea-level.

Culture: Good fibrous loam and leaf-soil, with protection from severe frost and damp in winter, are the conditions indicated.

PAXIANA (Gleig). Pax's P.

(Cortusoides-Geranioides.)

A tall, robust, perennial species with a large tuft of more or less erect, membranous leaves with rounded or kidney-shaped blades so much as six inches across; they are heart-shaped at the base and supported on slender, rounded, slightly downy stalks six to nine inches long; margins divided into seven to twelve short, broadly triangular, pointed lobes which are furnished with small, saw-like teeth; the nerves are sparsely covered with fine down. Flower stem fourteen to seventeen inches tall, slender, sparsely downy, bearing three to four superposed umbels of four to six bluish-lilac blossoms. Corolla about one inch across; lobes egg-shaped, deeply bifid; tube cylindric, about three times as long as the calyx. Introduced in 1909.

Grows in damp, grassy places on a rocky sub-soil, on the Lauschan mountains, near Dongerow, in the province of Kweichau, central China, at about 1,000 feet above sea-level.

Culture; Grow it in a mixture of good fibrous loam and sand, in a cool greenhouse.

PECTINATA (Balf. f.). Plume-leaved P.

(Souliei.)

A charming dwarf sub-species of P. incisa (Fr.), with rosettes of non-mealy leaves three-quarters-of-an-inch to one-and-a-half inch long, with oval or nearly circular blades, abruptly contracted into a stalk equalling the blade in length; margins pinnately incised; teeth oblong, entire, pointed, and fringed with minute hairs; both surfaces clothed with minute, meal-producing hairs, the underside being paler than the upper. Flower stem three to four inches tall, covered with minute, glandular hairs and bearing an umbel of about eight pale blue blossoms on rather long stalks, all facing the same direction on the stem. Corolla about five-eighths-of-an-inch across, with egg-shaped, bilobed segments. Flowers in August.

Grows in damp, rocky situations on the Muli mountains, in south-western Szechuan.

Culture: Good friable loam and grit, and a damp, open spot, are indicated.

PEDEMONTANA (Thomas). Piedmont P.
(Auricula-Erythrodrosum).

This attractive perennial species produces a tuft of narrowly-oval, egg-shaped or oblong-lance-shaped, fleshy, blunt or pointed leaves which gradually taper to a winged stalk, in all from three-quarters-of-an-inch to four inches long; margins entire or toothed, furnished with thick, reddish, glandular hairs; both surfaces nearly smooth. Flower stems three to six inches tall, glandular hairy, bearing an umbel of many rich, rosy-pink, white-eyed or rarely pure white blossoms, on stalks up to five-eighths-of-an-inch long. Corolla three-quarters-of-an-inch to one-and-a-quarter inch across, divided into five broadly heart-shaped, notched lobes; tube longer than the calyx, dilated upwards, covered with reddish, glandular down. Flowers in June and July. Introduced in 1826. *Bot. Mag.*, t. 5,794.

Grows on high, stony alpine ridges and moorlands, in peat, usually on a limestone formation, in the Graian and Cottian Alps.

Culture; Good calcareous loam and peat in a well-drained, open spot suits it; it fails in soil which is water-logged in winter.

PELLUCIDA (Franch.). Pellucid P.
(Malacoides).

This small annual species is probably closely related to P. Forbesii; it produces a weak tuft of intensely green, thin, membranous leaves from one inch to two-and-a-half inches long, including the slender stalk; the blades are oval and sparsely clothed with fine hairs, especially on the nerves beneath; they are heart-shaped at the base and their margins are furnished with rather widely-separated, blunt teeth. Flower stem hairy or smooth, from one inch to five inches tall, bearing one or two superposed umbels of pale, purple-violet or rosy-lilac blossoms, on stalks from three-eights-of-an-inch to three-quarters-of-an-inch long. Corolla three-eighths-of-an-inch to half-an-inch across; lobes broadly heart-shaped, cleft to the middle; tube cylindric, two or three times as long as the calyx. Not in cultivation.

Grows in damp, rocky places near Yunnan-Sen and Tchenfonchan, in Yunnan, western China.

Culture: As for P. Forbesii. *A. W. Darnell.*

(*To be continued*).

NURSERY NOTES.

MESSRS. R. WALLACE AND CO., LTD.

SITUATED on the outskirts of Tunbridge Wells, amid picturesque surroundings, are the nurseries of Messrs. R. Wallace and Co., Ltd., which are very appropriately known as "The Old Gardens." Upon entering the nurseries by the main entrance, on the Tunbridge Wells—Frant Road, the first impression is that of being in a large and old-established garden, rich in specimen trees and shrubs of great antiquity and charmingly laid out, with broad, winding paths edged with borders devoted to all manner of trees and shrubs, many of them rare and not often seen in this country.

The specimen Magnolias, for instance, are exceedingly fine, a tree of M. acuminata being of outstanding stature, while one of the quaintest features of the garden is a grand old tree of Sequoia gigantea var. pendula, which, with many others, was planted by the late Thomas Cripps, the founder of the nurseries. Giant trees of such Conifers as Libocedrus decurrens, Abies bracteata and an attractive pendulous form of Cedrus atlantica var. glauca, add to the charm to the scene, but the chief contributors to the general "long-established" effect are the wonderful bush and standard Rhododendrons, which, at the time of our visit, converted the nurseries into a paradise of colour.

The shrub borders are so designed as to remain attractive throughout the year, flowering and evergreen shrubs and Conifers being skilfully arranged, with here and there standard trees of flowering Cherries and Pyruses, and other subjects, including a good selection of Laburnums, noteworthy among which was L. vulgare var. Alschingeri, a late-flowering and distinct form with deep golden-yellow inflorescences. The specimens of Picea pungens var. Kosteriana and Juniperus chinensis var. Pfitzeriana, were specially interesting, and we also noticed what must be a very ancient specimen of Crataegus Oxycantha var. inermis compacta, very slow and close-growing, and now about six feet high.

The large plants of Liquidambar styraciflua, and the various Maples, must provide brilliant colouring in the autumn, while at the present season the numerous Brooms and Genistas; the various Diervillas, Styrax Obassia, various species of Roses, and many other shrubs, are flowering gaily.

We noticed a grand collection of Cistuses, while behind the shrub borders were large beds of various Conifers, standard Roses, ornamental Vines, American Thorns and ornamental flowering trees.

As stated, the Rhododendrons were the chief source of attraction, the "Rhododendron Drive," about a quarter-of-a-mile in length and forming an avenue of large standard trees of many grand old hybrids, with bushes of innumerable varieties and spaces beneath them, being a grand feature of the nurseries. Messrs. R. Wallace and Co. would appear to have a very extensive collection of species of Rhododendron, including many recent introductions by Farrer, Forrest and Kingdon Ward, and although, of course, these latter have not yet attained great size, many interesting plants were observed among them. Of the numerous species seen, mention may be made of R. muliense, R. coccinopeplum, R. yungningense and R. Wardii, R. Souliei, the low-growing R. kamtschaticum, and such large-leafed sorts as R. sino-grande, R. ficto-lacteum and R. Hodgsonii, with a host of the small-leafed, dwarf sorts, of the R. intricatum type. Very special species, of which we saw grand specimens, were R. Williamsianum, R. repens and R. orbiculare, the last-named belonging to the 'Thomsoni' series.

The hybrid Rhododendrons were legion. There were beds of many of the newer sorts, including Betty Wormald, with large, rich rose-coloured trusses of blooms; Hugh Wormald, cerise, with white stripes; Mrs. Lindsay Smith, a lovely pure-white variety; Sensation, white, flushed with rosy-lavender; and Kathleen Wallace, a grand late-flowering hybrid with lovely trusses of bright, glowing pink flowers.

The land to the left of the drive is devoted to various collections of shrubs and trees, such as Birches, Tilias, Crataegus, Azaleas, Maples, both American and Japanese, for which this firm is far-famed; Elms, among which Ulmus parvifolia was especially noteworthy; various Willows, including the lovely Salix magnifica; Magnolias, Deutzias, Philadelphuses and Diervillas. A very ancient specimen of the variegated form of the Tulip Tree, Liriodendron Tulipifera, is to be seen in this section, other good specimens being of the uncommon Maackia americana, and the American Red Oak, while we also admired some vigorous young plants of the much sought Davidia involucrata.

The shapely specimens of Japanese Maples—A. palmatum var. dissectum rubrum, together with the forms purpureum and palmatifidum—were also of special interest here, being richly coloured mounds quite six feet high, and wonderfully symmetrical in outline. There was also a unique collection of Barberries, both evergreen and deciduous, red-fruited sorts, the latter including such wonderful hybrids as B. rubrostilla, B. Autumn Beauty, B. Coral, B. Autumn Cheer, and several others, all of which originated at Wisley.

The collection of Olearias was also very interesting, a grand specimen plant of the uncommon O. virgata being noted, its slender growths having passed through last winter unscathed.

To the right of the Rhododendron Drive the ground rises, and from the summit is obtained a grand view of Tunbridge Wells and the Weald of Kent. In this section of the nurseries are yet other collections of shrubs, together with herbaceous and alpine plants, Liliums and other subjects.

There are large plantations of standard ornamental Apples and Plums, etc., various forms of Pyrus Aria, including the lovely variety lutescens and P. pinnatifolia var. Gibbsii, of comparatively recent introduction. Among the Sorbuses of note were Pyrus Vilmorinii, a free-fruiting Chinese species with very attractive foliage; P. Aucuparia var. discolor; P. rufo-ferruginea, of very graceful habit, and a valuable subject for autumn effect, its foliage taking on rich and varied tints, and P. pohuashanensis, a species from northern China, closely related to P. Aucuparia.

Messrs. R. Wallace and Co., Ltd., are famous throughout the world as purveyors of Irises and of Liliums, of both of which they have very representative collections; in fact, they would appear to have very comprehensive collections of every type of herbaceous and alpine plant, although space will not permit their enumeration on this occasion. A day is insufficient for the visitor to become acquainted with all the plants grown in these beautiful nurseries, but sufficient was seen during our short visit to convince us of the enormous variety of hardy plants, and especially of Rhododendrons, grown by this famous firm, and seldom have we seen so clean and well-cultivated a nursery, or such a grand collection of rare subjects.

FRUIT GARDEN.

SUMMER-PRUNING BUSH FRUITS.

MOST of the Black Currant fruits have now been gathered, except those on bushes growing in cool situations, or on those with a northern aspect. The bushes should be looked over, and much of the pruning necessary may be accomplished now, thus saving such work during the winter season. This pruning applies chiefly to the old and established bushes, as younger stock will require little pruning beyond the cutting out of the weakest branches that are inclined to hang too low. With the older bushes, however, the objects in pruning are to remove, or shorten, all the oldest wood that has fruited, and to retain so much of the young wood as possible, without undue crowding. This thinning will permit all the light and air to reach and ripen the young shoots on which are obtained the finest fruits each year. The crops here, this year, have been clean and excellent in every way. The variety Boskoop Giant is par excellence as an early jam variety, and is followed by Seabrook's Black, Goliath and Baldwin, in order of ripening.

Red and White Currants also are greatly benefited by summer pruning, and with these it is not necessary that the crop should first be cleared. The bushes should be gone over with a pair of secateurs, and all lateral growths not required for rejuvenating purposes should be cut back to four or five leaves from the base, and the leaders, or extension shoots, to ten or twelve inches. This shortening of the shoots improves the size and quality of the fruits hanging, and the basal buds are "plumped up" and ripened by the concentration of food, and the additional light and air. Those who have not grown Laxton's Perfection Red Currant should give it a trial. It bears a very heavy crop of fruits of the largest size, and produces bunches three to four inches in length, with as many as twenty-six fruits in each.

Gooseberries should be pruned in the same way as the Red Currants. This seems to be absolutely necessary in the case of bushes up to the age of six or eight years, especially if they are growing in fairly rich soil. The growths on these young bushes are usually so strong that a great many snap off at the base, causing the bushes to become one-sided and badly shaped. This is particularly annoying in the case of the main leader shoots. These should be shortened slightly so that they can withstand the strain. All lateral growths should be cut back to four or five leaves, any well-situated shoots on these main branches being reserved, where space permits, to replace the old ones as time goes on. This is essential in varieties with a pendulous habit. *H. H. Cook, Reading University Horticultural College.*

HOME CORRESPONDENCE.

[*The Editors do not hold themselves responsible for the opinions expressed by correspondents.*]

A Spineless Thistle.—The above title might be applied to Cnicus montanus, more often named Cirsium montanum on the Continent, for the few small bristles on the margins of the leaves do not feel prickly to the fingers. The involucral leaves surrounding the flower-heads also feel soft to the touch. The heads themselves are deep purple, and borne in a cluster of three to six at the top of stems about four feet high. Among all the species of Thistle that have been introduced to this country at different times, I cannot find any reference to its introduction, although it has found its way into some private gardens. I had a specimen of it from Mr. F. J. Hanbury, Brockhurst, East Grinstead. In Europe, it grows in woods and ravines in the Lower Alps, the Maritime Alps, the Tirol, Liguria, Croatia and Transylvania. As a garden plant it could be grown in the herbaceous border, while its ample leaves would make it suitable for the wild garden. The flowers of these Thistles are mostly scented, the mild, musky odour being agreeable, rather than otherwise. *J. Fraser.*

Flowering of Actinidia chinensis.—In view of the correspondence occurring on pages 208, 307 and 487 (of *The Gardeners' Chronicle*, Vol. LXXXIV (1928)), with reference to the flowering of this climber, the enclosed blossoms are interesting. They were taken from a plant growing on a pergola at the Municipal Gardens, York House, Twickenham, and, as far as the oldest employee remembers, this is the first occasion this plant, although established for a long period, has produced flowers. Annual spurring back may have been responsible for its failure to flower hitherto, although some writers appear to recommend this treatment. It is interesting, however, that in this case no pruning has taken place for a period of three or more years. Another specimen growing against a wall, and enjoying the same aspect and soil conditions, but annually spurred, shows no sign of flowering. This Actinidia is a climber of exceptional beauty, and when fully established is very free-growing the finely-pointed tips of the young shoots being densely covered with a conspicuous mass of red hairs, which, together with the rich, elegantly-formed foliage, makes it a subject of prominence and great merit. *H. G. King, Twickenham.*

Nurserymen's Descriptions of Flowers.—I think that gardeners, professional and otherwise, have a very just cause of complaint against nurserymen and seedsmen for their descriptions of the colours of plants. The descriptions often are so exaggerated that it is really laughable, and sometimes disastrous for the poor gardener, if he has any child-like faith left in him in reference to colour and seedsmen. A gardener may wake on a sunny morning with the thought that his bed of Petunia Crimson Scarlet should be looking well. What does he find ? A bed of black flowers, for all practical purposes ! Then he tries with Silene Scarlet, for a bordering plant. It looks so neat and charming that he feels sure he has got a real gem as an edging to a bed of small-flowered scarlet Begonias ! It flowers—with sad results ! All the same, the Silene is a beautiful little plant in the right place. *Samares.*

Lonicera nitida.—In *The Gardeners' Chronicle* of September 24, 1927, appeared a note on this species by *A. O.*, who referred to the yellow flowers and blue berries, and I shall be glad if he can give any hints as to soil and treatment to ensure flowering and fruiting, because, although this shrub is grown commonly about here for hedges, etc., everyone I have asked seems never to have seen it in flower, although in some cases it is in bush form six feet or more in height. Mr. J. Fraser suggests that possibly it requires more sun than is generally available in this country ! If that be so, then this year, with its abnormal allowance, should be favourable. Will any reader who successfully flowers and fruits it, give us the benefit of his advice as to treatment ? Probably severe clipping is undesirable. *C. Nicholson.*

SOCIETIES.

WOLVERHAMPTON FLORAL FÊTE.

This annual flower show and fête is now very largely in the hands of the Corporation, and has thus been saved from the extinction that threatened it after the appalling wet weather experienced during the function of two years ago. Many additional attractions are now offered, including a military tattoo during the evening.

The exhibition held in West Park on July 16, 17 and 18 was the largest and best we have seen at Wolverhampton, and certain enthusiastic members of the Committee stated that it occupied more space than the Southport Show. Trade displays were unusually numerous and extensive, and the largest tent was filled with them, two very notable displays being the gardens and floral designs exhibited by Messrs. Bakers and Messrs. Knight.

Competition was, on the whole, keen, and there was such a rush of entries just before the books were closed that two extra tents had to be provided. This threw a good deal of extra work upon the judges, few of whom finished their task before 1.30. If the extent of the fête is maintained or increased, the management should seriously consider the appointment of more judges and an earlier hour for them to commence their duties. A minor matter is the time of the luncheon ; on this occasion it commenced about forty minutes after the time stated, with the result that several visitors who had long journeys before them and had to leave the grounds by two o'clock, were unable to take full advantage of the hospitality that had been offered them.

Groups and Plants.

There was a falling off in the big group classes, the competition being confined to Sir G. H. Kenrick (gr. Mr. J. Macdonald), Whetstone, Birmingham, and Messrs. Jas. Cypher and Sons, Cheltenham. The former won first prize for a miscellaneous group, artistically displayed on a space twenty-eight feet by twelve feet, with an elegant display wherein Palms, Codiaeums, Ferns, foliage Begonias and Humea elegans were associated in pleasing fashion, and such bold flowering plants as Fuchsias, Liliums, Francoa ramosa, Thunias, Oncidiums and Cattleyas. Messrs. Jas. Cypher and Sons received second prize, but in the class for a display of ornamental foliage plants arranged on a space of two hundred square feet, the Cheltenham firm beat Sir G. H. Kenrick, with a very fine contribution in which the leading features were Caladiums, Codiaeums, Palms, foliage Begonias, Alocasias, Nandina domestica, Dracaenas, Ferns and Asparagus. Mr. Macdonald's second prize group was, of course, a thoroughly praiseworthy exhibit by this veteran and clever grower.

J. L. Swanson, Esq., showed the best amateur's group of plants and made a fine display with Humeas, Calceolaria Clibrani, Codiaeums, Nandinas, Liliums and Francoa ramosa, and an edging of Nertera depressa ; second, G. Mason, Esq. (gr. Mr. Clark) ; third, P. Jones. Esq.

J. L. Swanson, Esq., won first prize for a collection of decorative plants and cut flowers, arranged for effect on a space six feet by four feet ; he used Lilium Henryi, Carnations, Codiaeums and Begonias skilfully ; second, F. E. Sankey, Esq., who staged Francoas, Carnations, Clarkias and Statice Suworowii.

In the class for a group of one kind of flowering plant, F. E. Sankey, Esq., led with Heliotropes, followed by Sir Charles Fenn (gr. Mr. Ratcliffe), Kingswinford, with Francoa ramosa.

Messrs. Jas. Cypher and Sons led for fifteen plants in pots, with a bright and attractive set.

Major S. J. Thomson exhibited the best dozen flowering plants of one kind in the amateurs' section, winning with fine Begonias ; second, G. Mason, Esq., also with Begonias ; third, F. F. Sharpe, Esq. (gr. Mr. Cotton), with Fuchsias.

The class for a group of Fuchsias was well filled, and as Fuchsias are again becoming popular, the class proved very interesting. First prize was won by Messrs. Ramsbotham and Co., Bletchley, with neat plants of Amy Lye, Bluebell, Jock French, Favourite, etc. ; second, Mr. F. F. Sharpe ; third, Mr. F. E. Sankey.

Tuberous-rooted Begonias were shown splendidly, and the several competitors in the class for a group arranged on a table space of twenty feet by four feet produced a fine bank of colour. The Challenge Trophy presented by Messrs. Blackmore and Langdon was won by Major S. J. Thompson (gr. Mr. J. White), Oaken, with a display of finely grown plants that would have been a credit to the donors of the Cup ; double and single varieties, and pendant sorts in hanging baskets, were all splendidly grown ; second, Alderman A. B. Bantock (gr. Mr. M. Woodham) ; third, J. L. Swanson, Esq.

Roses.

Roses soon felt the effects of the bright sunshine and heat. Messrs. Gunn and Son had the finest collection of cut Roses, and produced a striking effect with pillars, baskets and vases of Mabel Morse, Gwenneth Jones, Lady Inchiquin, Golden Emblem, Doris Trayler, Desmond Johnson, Betty Uprichard, and other fine varieties ; second, Messrs. W. Lowe and Son ; third, Mr. Elisha J. Hicks ; fourth, Messrs. Horton Brothers.

In another class for a smaller collection, Mr. M. Townsend was the leading prize-winner, and showed fine examples of Mabel Morse, W. H. Drew, Los Angeles and Mrs. Henry Morse ; second, Mr. Charles Gregory ; third, Mr. J. Mattock.

Mr. George Prince led for nine perpetual-flowering Roses, and the Donard Nursery Co., led for six Roses, three blooms of each. Mr. C. Gregory showed the best eighteen Roses.

Dowty's Rosery, Wolverhampton, contributed a goodly collection of Roses, winning first prize with capital flowers of Angele Pernet, Hortulanus Buddé, Mrs. Henry Morse, Mrs. H. Stevens, Mrs. Barraclough and other notable varieties ; second, Mr. G. Prince ; third, Mr. J. Mattock.

C. B. Worsey, Esq. (gr. Mr. A. Davis), and Jarratt Thorpe, Esq., were successful amateur exhibitors of Roses.

Hardy Flowers.

Messrs. Bees, Ltd., secured first prize for an arrangement of hardy flowers, with one of their splendid displays wherein a few of the best kinds were Lilium pardalinum, L. regale, L. Henryi, Centaurea macrocephala, and various Delphiniums and Phloxes. Mr. D. Green scored for Antirrhinums, followed in order by F. E. Sankey, Esq. (gr. Mr. R. Maybury), Wolverhampton ; and Mr. P. Adams ; all showed well.

Messrs. Bees, Ltd., were easily first prize-winners in the class for a collection of Delphiniums, and their spikes were in fine condition, despite the weather ; theirs was a grand exhibit of varieties of this popular flower, and it covered a space twenty-four feet by eight feet ; second, Messrs. Hewitt, Ltd.

Mr. L. E. Holland, had the best half-a-dozen bunches of hardy flowers and also the best three bunches of old-fashioned flowers, showing Antirrhinums, Larkspurs and Poppies. Mr. G. H. Brookshaw, Crewe, led for annual flowers ; second, Mr. W. J. Robinson, Banbury.

Sweet Peas and Carnations.

The best set of bouquets or baskets of Sweet Peas was the one arranged by Davis Green, Esq. (gr. Mr. W. Thorneycroft), whose Gleneagles, Hero, Olympia and Magnet were particularly good ; second, Mr. G. H. Brookshaw, Crewe ; third, Mrs. N. N. Richards (gr. Mr. Horton), Denbigh.

Mr. F. Tennant, Clent, and Mr. S. Roberts, Finchford, and Mr. F. Marsden, won prizes for Sweet Peas in the amateurs' classes.

Jarratt Thorpe, Esq. (gr. Mr. Bircher), Hucclecote, Gloucester, showed the best set of twelve varieties of Sweet Peas, and Mr. J. Robeson, Banbury, won second prize. Mr. J. Thorpe also won first prize for a display of Sweet Peas, with Mr. J. Stevenson, second. Sir R. Baker (gr. Mr. A. E. Usher), Ranston, Blandford, had a very fine collection of Sweet Peas that included Gold Crest, Pinkie, Southport, What Joy, Mammoth, R. Felton, Powerscourt, Magnet and Model; second, Mr. A. Challoner, Balterley, Crewe.

Mr. Charles Wall contributed the finest display of Carnations, and included in his group excellent flowers of Laddie, Topsy, Spectrum and Saffron; second, Messrs. C. Engelmann, Ltd. Mr. Charles White was the most successful exhibitor of border Carnations and Picotees, followed by S. Pye, Esq. (gr. Mr. Holmes), Garstang; and Mr. A. Reynolds.

Table Decorations.

Sir E. H. Kenrick won first prize for a table decoration, in the open section, with a charming arrangement of Gloriosas, Oncidiums and Epidendrums; second, Mr. A. A. Yates, Warwick; third, J. L. Swanson, Esq. (gr. Mr. F. W. Cosling), Wolverhampton.

In the amateurs' class for a table decoration, Mrs. Q. W. Hosier, Willenhall, led with a design in Madame Butterfly Roses; second, Mrs. A. E. Reeves, Walsall, with Golden Ophelia Roses; third, Mrs. H. Hands, Bridgenorth.

Vegetables.

H. S. Pitt, Esq. (gr. Mr. J. Cook), Kingswinford, won the first of Messrs. E. Webb and Sons' prizes for a collection of eight distinct kinds of vegetables with well-grown examples of Potatos, Onions, Peas, Carrots, Cucumbers, Cauliflowers, Tomatos and French Beans; second, A. H. Hickman, Esq. (gr. Mr. J. Parker), Cookley; third, Mrs. P. Adams (gr. Mr. Pugh), Kidderminster.

Medal Awards.

Large Gold Medal and Silver Challenge Trophy.—For the best non-competitive exhibit in the show. To Messrs. Bakers, Wolverhampton, for formal garden, rock garden and floral designs.

Large Gold Medal and Special Cultural Commendation.—To Lord Leconfield (gr. Mr. Streeter), Petworth, for a collection of vegetables.

Large Gold Medals.—To Messrs. Sutton and Sons, for a display of Sweet Peas; Messrs. E. Webb and Son, for a group of flowers, fruits and vegetables: Mr. Thomas Robinson, for Roses; Messrs. Knight, for a sunk garden; and to Messrs. Blackmore and Langdon, for Begonias and Delphiniums.

Gold Medal.—To the Wolverhampton Corporation, for a group of plants.

Silver-gilt Medals.—To Messrs. Murrell, Shrewsbury, for Roses; Messrs. Toogood and Son, for flowers and fruits; and to Messrs. Dobbie and Co., for Roses.

Silver Medals.—To Messrs. P. and F. Smith, Ltd., for a rock garden; Messrs. Isaac House and Son, for Scabious; Messrs. T. Grove and Son, for hardy flowers; Messrs. Maxwell and Beale, for hardy and alpine plants; Mr. H. Ellison, for Ferns; and to Messrs. Jarman and Co., for hardy flowers.

BRITISH CARNATION.

July 18 and 19.—For the second successive year, the British Carnation Society and the National Carnation and Picotee Society joined forces and held a combined show at Westminster. It was hoped that the new Horticultural Hall would have been filled entirely with Carnations and allied flowers, but while this hope was not materialised, there was a very attractive show. The arrangements were well conceived and the first impression—always an important matter—was admirable. Immediately on entering the hall, the visitor saw a most magnificent group of Carnations, and was enveloped with their delicious fragrance. In both sections the quality of the blooms reached a high standard of excellence, but there is room for more exhibitors in most classes, although there was a welcome revival in the class for growing plants in pots, in which four admirable collections were arranged. The trade members ably supported the show, and their handsome collections were of immense value. The various arrangements under the two enthusiastic new Hon. Secretaries, Mr. F. W. Alesworth and Mr. A. E. Amos, worked smoothly and well.

Trade Classes.

The nine varieties in competition for the right to hold the *Daily Mail* Challenge Cup for a year were set out in the dais. The Cup is offered for the best-scented Carnation not in commerce prior to 1927. The Cup was rightly awarded to the pale pink Mavis, shown by Messrs. Walter Hemus, Ltd., which won the Cup two years ago. It is a well-formed, serrated bloom of most delicious fragrance. Other varieties in the competition included Guy Allwood, a sweetly scented pink variety, shown by Messrs. Allwood Bros.; G. F. Phillips, fragrant, deep crimson, shown by Messrs. Hewitts; Dorcas, a medium-sized, compactly-formed, sweet, rich crimson variety, shown by Messrs. C. Engelmann, Ltd.; Sonny Boy, rose pink and of fair fragrance, shown by Mr. A. F. Dutton; and Fragrance, a small scarlet, fragrant flower, also shown by Mr. A. F. Dutton.

Only Messrs. C. Engelmann, Ltd., staged twenty-five blooms each of seven distinct varieties, but this was a magnificent exhibit and fully deserved the first prize. The varieties were Brilliant, Saffron, Master M. Stoop, Hebe, Blanche, Sunny and Topsy. The first prize for three vases, twelve blooms in each, of British novelties, was shown by Messrs. Allwood Bros., who staged exceedingly good blooms of Brilliant, Rapture and Guy Allwood. Messrs. C. Engelmann, Ltd., were a good second. In the class for twenty-five blooms of Spectrum, the positions were reversed, and Messrs. C. Engelmann, Ltd., won the American Carnation Society's Cup with splendid blooms.

There were five superb exhibits of a vase containing not fewer than one hundred blooms of any one variety, and here Messrs. C. Engelmann, Ltd., were first with an excellent vase of Laddie; and Messrs. Walter Hemus, Ltd., were second, with Dora. Showing Laddie, Red Laddie, Topsy and Blanche, of high quality, Messrs. C. Engelmann, Ltd., were first in the class for a vase of fifty blooms in four varieties, and Messrs. Allwood Bros. were a good second. The best twenty-five blooms of a British-raised variety were those of Pink Seedling, shown by Messrs. Allwood Bros., while Startler, shown by Messrs. C. Engelmann, Ltd., must have been a close second. Topsy, staged by Messrs. C. Engelmann, Ltd., was the best fragrant crimson variety.

The colour classes were of interest and value as showing the best exhibition varieties in the various sections. Showing Sunny, Laddie and Red Laddie, Messrs. C. Engelmann, Ltd., were first in the class for twenty-five blooms, each of distinct colours. White Pearl, shown by Messrs. Allwood Bros., was the best white Carnation, and Messrs. C. Engelmann, Ltd., were second with the same variety, and their first prize flowers of Laddie in the class for a light pink variety were distinctly the finest blooms in the show. Mary Allwood was shown both by Messrs. Allwood Bros. and Messrs. C. Engelmann, Ltd., in the class for a medium pink variety. Master M. Stoop, shown by Messrs. C. Engelmann, Ltd., was the best deep pink, and Red Laddie, of superb quality, and by the same exhibitors, was the best red Carnation. Topsy, shown by Mr. H. T. Mason, who was first, and by Messrs. C. Engelmann, Ltd., who were second, was the best variety of its class. Wivelsfield Claret Improved, shown by Messrs. Allwood Bros., was the best purple or mauve variety, and the same exhibitors were first with Wivelsfield Buttercup in the class for a yellow or yellow Fancy variety. Chintz, shown by Messrs. C. Engelmann, Ltd., was the best Fancy Carnation other than yellow, and Coral Glow, by the same exhibitors, was first in the class for twenty-five blooms of Carnations of apricot and yellow shades.

Amateurs' Classes.

The four exhibits of twelve plants of perpetual-flowering Carnations were all highly creditable to the growers and made a very attractive feature of the show. The first prize was won by Lord Woolavington (gr. Mr. E. W. Fuller), Lavington Park, Petworth, whose splendid plants were of Eileen Low, Topsy, Lady Hindlip, Mary Allwood and Saffron. Lady Emsley Carr (gr. Mr. J. Doe), Wonford, Walton-on-the-Hill, showing fine plants of Lady Hindlip and Philip Sassoon, was a worthy second, and Mr. William Holder, New Lodge Clinic, Windsor, was third, with plants which at some former shows would have won the first prize.

The three decorative arrangements of cut Carnations also were of high quality. Lady Emsley Carr was first with a handsome display which included Philip Sassoon, Lady Hindlip and Red Ensign, of high quality. E. Martin Smith, Esq. (gr. Mr. G. J. Miller), Codicote Lodge, Welwyn, was a good second, and Lady Brodie Henderson (gr. Mr. W. Eggleton), Epping House, Hertford, was third. Mr. W. Holder won the Stuart Low Challenge Cup with a splendid vase of Carnations.

Lady Melchett, D.B.E., Melchet Court, Romsey, who staged good rose, cerise, yellow, scarlet and Fancy seedlings, was first in the class for seedlings raised and grown by the exhibitor. Mr. Henry Atkins won first prizes for a decorative vase of not more than twenty-five blooms, with Laddie, in the light pink class; and White Pearl, Topsy and Maine Sunshine in the colour classes. First prizes in these classes were also won by the Hon. George Herbert, Knowle House, Salisbury, with Master M. Stoop and Red Laddie; Lady Melchett, with Mrs. H. Fellowes; E. Martin Smith, Esq., with Iona, and a vase of mixed Fancy varieties. F. V. Wharmby, Esq., Thornton Heath, and W. E. Tucker, Esq., Bournemouth, were the most successful exhibitors in the classes for amateurs who do not employ a full-time gardener.

In the decorative classes the amateur exhibitors clearly outshone the professionals, whose exhibits were mostly heavy and massive. The first prize dinner table decoration of Carnations was arranged by Miss M. Woolven, Wadlands, East Grinstead, who used Fancy shaded varieties very effectively. J. G. Miller, Esq., was second. Both Mrs. A. Swann, Haywards Heath, and Miss Woolven, who were first and second, respectively, in the class for a dinner table decoration of Dianthus Allwoodii used the variety Sylvia very tastefully. Mr. William Holder was first with a well arranged bowl of Carnations, and Mrs. Swann was first with a bowl of Dianthus Allwoodii. The baskets of Carnations were especially successful, and Miss Woolven was first with a delightful arrangement of Spectrum and Croton leaves.

In the Florists' Section, Messrs. Selfridge were first in the dinner table decoration class, and Messrs. Robert Green, Ltd., won the other first prizes. As we have stated, the arrangements were inferior generally to those of the amateurs; the exception was a bowl of red cerise Carnations and yellow Croton leaves, arranged by Messrs. Robert Green, Ltd., which was of considerable artistic merit.

The classes for pots or pans of Rock Dianthi did not appear to bring any exhibit. R. Chetwynd Stapleton, Esq., Headlands, Berkhamstead, who showed Rhodo, Barbara and Nora, was first for six vases of Pinks and Hybrid Pinks. Lady Brodie Henderson was first with three vases. Mr. Henry Atkins was first with a vase of Malmaisons, and E. Martin Smith, Esq., was first with Sweet Williams and seedling Carnations.

There were five boxes of Carnations in the class arranged to test their travelling and keeping qualities. The boxes were sent by post to the secretary at the hall where they were opened and flowers were placed in water. The judging took place on the following day when the W. E. Wallace Cup and first prize were awarded to Messrs C. Engelmann, Ltd., for their box of Laddie.

Non-Competitive Exhibits.

A magnificent display of first-rate Carnations was made by Messrs. C. Engelmann, Ltd. Their group was composed of baskets and ornamental jars, which contained all the best market varieties, and it was arranged with consummate taste and skill. The raised baskets were filled with such varieties as Brilliant, Rouge and Master M. Stoop, while at the corners there were jars of Cupid, Saffron, Mab and Canadian Pink. Other varieties which helped to make this memorable display were Madge, Nero, and Sheila Greer, of the Fancy varieties, Red Laddie and Mrs. Walter Hemus.

In a tasteful oblong group of fine Carnations, Messrs. Allwood Bros. included very good vases of the Malmaison varieties Princess of Wales and Old Blush, which were deliciously fragrant. Their perpetual-flowering varieties embraced Guy Allwood, Mary Allwood, Buttercup, Shot Silk, Mrs. E. W. Ward, Edmund Allwood, Topsy, Triumph and Spectrum.

On a wall space, Messrs. Keith Luxford and Co. had a collection of perpetual-flowering Carnations which suffered a little in decorative value from a too free use of pot Ferns. The Carnations included good vases of Spectrum, Lady Hindlip, Mikado, May Day and Mrs. Walter Hemus.

NATIONAL CARNATION AND PICOTEE.

Although the section of the show arranged by this Society was not so big nor so imposing as that of the British Carnation Society, there was, nevertheless, a bright display of border Carnations, and despite the trying weather conditions, which had a restricting effect on the number of entries, many grand and exquisite blooms were staged, especially by Miss Shiffner, Lewes, who was the chief prize-winner.

Mr. J. Douglas, Messrs. Lowe and Gibson, Ltd., and Miss Shiffner shared the premier awards in the open classes. The first-named exhibitor was first for seven blooms of a pink or rose self-coloured Carnation, showing grand blooms of Dora Spendlow; for a dark red or maroon variety, showing Rhoderic Dhu, crimson, shaded with velvet; for a buff or terra-cotta variety, with Homer, delicate terra-cotta; for any other self-coloured variety, showing Misty Morning; for a yellow-ground Picotee, with Fairy, a small bloom, creamy-yellow edged with pink; and for a Clove-scented variety, showing lovely blooms of Edenside Clove.

Messrs. Lowe and Gibson, Ltd., secured the premier awards in the classes for seven blooms of a white border Carnation, showing Snowflake in good condition; a yellow variety, with Mary Murray; and a white-ground Fancy, with Florence Wellstead, white, edged and flecked with red; while Miss Shiffner was placed first for seven blooms of a red or scarlet variety, displaying exceedingly well-grown blooms of Bookham Scarlet; a yellow or buff-ground Fancy, with Kitro, orange-buff with purple markings; and for any Fancy variety, other than with a yellow or buff ground.

In the second division, for amateurs, Miss Shiffner led in twelve out of the sixteen classes, showing grand blooms in every instance; the other first-prize winners in this section were Mr. J. Fairlie, Acton, for three varieties of white-ground Picotees, and for one variety of a self Carnation, of any colour not mentioned in the special colour classes; and Mr. E. Charrington, Limpsfield, for a white-ground Fancy; Miss Shiffner and Professor F. W. Burstall, Birmingham, shared the second prize in the class for a pink or rose self-coloured variety, no first prize being given.

In Division 3, also open only to amateurs, Mr. E. Jones, Moseley, was the chief prize-winner, securing eight first prizes out of nine, Captain E. M. Wilkinson, Southampton, securing the remaining premier award; while in Division 4, Mr. J. T. Standfast was first for one vase of self-coloured Carnations; Mr. H. Charles, Birmingham, led for one vase of yellow-ground Fancies; for one vase of white-ground Fancies, and for one vase of Clove-scented Carnations; and Mr. W. Lamb, Chigwell, was successful in the class for one vase of Fancies other than white or yellow-ground.

Mr. H. Dellow, Chingford, was successful in the Novices' Class which required one vase of five blooms, one or more varieties, showing good examples of Woodpark, Montrose, Joan Wardle, Mrs. R. Carpenter and Sheila Gibson. Mr. G. D. Murray was first for one or more vases of seedling Carnations, while in the special class for affiliated societies, the only Society to stage an exhibit of twelve blooms of border Carnations was the Liverpool Victoria Horticultural Society, which was awarded the first prize.

In the competition for the President's Silver Challenge Bowl, for a trade exhibit of border Carnations and Picotees on a space eighteen feet by six feet, Mr. James Douglas was first with a charming collection, his outstanding varieties being Dora Spendlow, Bookham Pink, Rattachan, scarlet; Highland Mary, Snowflake, Kate Seaton, Prince John, Misty Morning, St. Joan and Fancy Free; second, Mr. H. Woolman, who included lovely blooms of Undine, Plum, Florence Grisby, Bookham Rose and British Legion; third, Messrs. Lowe and Gibson, Ltd.

The last-named firm was first in the open class for fifteen vases of not less than ten varieties, with a grand set which included lovely blooms of Peach Blossom, Florence Grisby, Viceroy, Corinthian, Joan Wardale and Maisie Lowe; second, Mr. J. Fairlie, whose best blooms were of Sam Griffiths, Ravenswood, May Morning, Bookham Beau and Steerforth.

Miss Shiffner secured the Edith Drake Challenge Cup, for a decorative vase of fifteen blooms; Messrs. Lowe and Gibson, Ltd., showed the best decorative vase of eleven blooms, and Mr. E. Charrington was first for a vase of seven blooms of hardy border Pinks.

Non-Competitive.

These were not numerous. Mr. C. H. Herbert had a collection of his well-known border Pinks, including such varieties as Prince of Wales, pale cerise; Othello, deep, crimson; Mrs. Herbert, bright pink, blotched with red at the base; and Fire King. Messrs. Allwood Bros. staged an extensive collection of border Carnations, and also had groups of Allwoodii Pinks and Dianthus Sweet Wivelsfield; while Messrs. P. S. Hayward and Sons showed a distinct strain of Dianthuses, in several unique colour forms.

NATIONAL ROSE.

July 23.—The show of New Roses which now has become an annual fixture with the National Rose Society, was held in the new Horticultural Hall, Westminster, on this date. Although in some districts an almost tropical downpour was experienced last Saturday, the chief Rose-growing districts did not share the welcome rain, and as the great heat continued, first-grade exhibition Roses were not to be expected; in fact, it was to all intents and purposes a show of garden Roses and, in spite of all the drawbacks of the season, it was a very good show. The trade growers supported the show admirably, and the two classes of groups of representative Roses were especially delightful. The amateurs also set up many good exhibits. There were over fifty new seedling Roses submitted for award, but it must be confessed that even after making allowances for the season, they were not altogether a distinguished gathering. There was no Gold Medal Rose, and in awarding six Certificates of Merit the Council were more than a little kind. Generally, the best of the fifty odd new Roses were those which have previously received the Certificate of Merit, but none of these gave any present impression of being a serious candidate for the higher award, although well worthy of the present position.

Certificates of Merit.

Caledonia.—A substantial and well-formed H.T. variety which is recommended for exhibition and garden purposes. It is of good habit, and the shapely blooms are borne on long and sufficiently stout stems. The foliage is good, and the colour is paper-white with a lemon-yellow glow in the heart of the bloom. Shown by Messrs. Dobbie and Co.

Katherine King.—We are inclined to suspect that the award to this variety is of the nature of an encouragement. Although classed as a H.T. it is more suggestive of the H.P. type. The foliage is abundant, probably too abundant for popular favour, the colour is pink, and the flowers are pleasantly scented. Shown by Mr. G. Marriott, Carlton, Notts.

Lucie Marie.—An H.T. variety recommended for the garden and bedding. The blooms are shapely but of very variable shades of colour, ranging from yellow to a soft orange tint. Some of the petals are lightly lined with peach-pink. The foliage is stout and dark, shining green, and the blooms have a slight fragrance. Shown by Messrs. Alex. Dickson and Sons.

Senorita de Alvarez.—A very beautiful and fascinating, large, single H.T. Rose of the same type as the popular Isobel, which it is likely to rival and even surpass. The flower measures between four and five inches across. The substantial petals are of bright satiny-pink colour. The small cluster of yellow stamens is surrounded by a narrow zone of rich golden-yellow. Shown by Messrs. B. R. Cant and Sons.

Tom Barr.—A pretty H.T. variety of slightly variable colouring, which appears to have distinct garden value. The flowers are of medium size, fully double, and the general colour tone seems to be apricot, flushed with rosy-cardinal. The plants have neat, shining foliage, and the flowers are lightly scented. Shown by Messrs. S. McGredy and Son.

W. E. Chaplin.—A fully double H.T. Rose of rather more than average size, good shape and deep rose-pink colour. Shown by Messrs. Chaplin Bros.

Other New Roses.

As we have suggested, several of the novelties which have previously received the Society's Certificate of Merit disclosed distinct attractions even although they did not warrant promotion in the honours list. The best of these were the deep rosy-salmon Rose Berkley, the bright rose and gold Cherry, and the golden-salmon Portadown Fragrance, raised by Messrs. S. McGredy and Son, and the china-pink hybrid Musk Felicia, raised by Mr. J. H. Pemberton. The more recent novelties of merit included Lady Leslie, a very fragrant, glowing rose-cerise H.T., shown by Messrs. S. McGredy and Son; Marchioness of Linlithgow, a rich velvety crimson H.T. of decided fragrance and a rose-scarlet glow on the blooms, raised by Messrs. Dobbie and Co.; Joan Cant, a very sweet H.T. of Malmaison pink in the centre and a paler pink on the mature petals, shown by Messrs. B. R. Cant and Sons; and Gloria Mundi, an intense scarlet Polyantha Rose, shown by Mr. A. de Ruiter, although, unfortunately, there is something lacking in its habit.

Groups of Roses.

The large groups of representative Roses filled the wall space and contained very beautiful Roses. The first prize was won by Messrs. S. McGredy and Son with a tasteful arrangement which included handsome pillars of Mrs. C. Lamplough, which was decidedly the Rose of the show; Mrs. Henry Bowles and Hortulanus Budde. They also had generous baskets of McGredy's Ivory, Lady Inchiquin, Patience and Mrs. A. R. Barraclough. In their good second prize group, Messrs. Chaplin Bros. had many clean and well-coloured blooms of Waltham Cross, Mrs. Henry Bowles, Innocence, Isobel, Los Angeles and Mabel Morse. Mr. H. J. Pemberton, who was third, used Mermaid, Pax, Madame Butterfly, Paul's Scarlet Climber, and Bernice to good effect. Messrs. B. R. Cant and Sons were fourth with a very pretty group.

The best of the many smaller groups of cut Roses was set up by Messrs. Harkness and Co., and this contained magnificent baskets of Mrs. A. R. Barraclough and Mrs. C. Lamplough, with stands of Lady Inchiquin and Madame Butterfly, and an arch of Allan Chandler. The centre of Mr. George Prince's group was composed of Mabel Morse, and the *Daily Mail* Scented Rose, flanked by Dame Edith Helen, Madame Butterfly and Allan Chandler. Mr. C. Gregory was third, and the Dowty's Rosery fourth.

The baskets of Roses were of good quality. The best three were those of Lord Charlemont, Ruth and Margaret Anne Baxter, shown by Messrs. T. Smith and Son, while Mr. G. Burch was second. The first prize in the class for twenty-four exhibition Roses was awarded to Messrs. T. Smith and Son, and Mr. C. Gregory was second, both staging blooms so overdressed that their character was spoilt. Messrs. B. R. Cant and Sons were third with a more pleasing exhibit. A first prize was awarded to Mr. G. Burch for a very good collection which included Mrs. A. Carnegie, Dean Hole, George Dickson, and Mrs. C. Lamplough. Mr. Henry Drew in his good second prize exhibit, had particularly good blooms of Mrs. C. Lamplough, Mrs. E. J. Hicks and Mrs. Foley Hobbs. Mr. Henry Drew, showing Mrs. A. R. Barraclough and Mrs. Henry Bowles, of great beauty, was the first of the seven exhibitors of two baskets of Roses. Mr. C. Gregory was second.

Amateurs' Classes.

In his first prize exhibit of exhibition Roses in boxes, Mr. H. F. Spicer included, in George Dickson, the best bloom of the section, and also staged creditable specimens of Dame Edith Helen, Candeur Lyonnaise and Madame Louise Crette. Mr. J. E. Rayer was second, and he showed Mrs. C. Lamplough and H. V. Machin, of good quality. Mr. W. E. Moore had the best six blooms, and his best were Mrs. C. Lamplough and Mrs. E. J. Hudson. Mr. Norman Fletcher showed good blooms of Ethel and Mrs. C. Lamplough. In the class for six vases of decorative Roses, Mr. S. E. Tattershall was first with very good vases of Padre, Lady Gay and Joana Bridge. Mr. R. C. Wallhead was similarly successful with Paul's Scarlet Climber, Excelsa and Souvenir de Claudius Pernet. Mr. E. H. Pleasance won a first prize with George Dickson, Coronation and other good varieties; while in the next class, Mr. George Marriott showed particularly good examples of Golden Emblem, Los Angeles and Souvenir de Claudius Pernet.

The decorative classes were all well contested. Mrs. Tisdall was first in the Nurserymen's Dinner Table class, with a tasteful arrangement of Roselandia, and was also first with a bowl of the same variety. In the amateurs' section, Mrs. Courtney Page was first with a charming dinner table of Emma Wright, and Mrs. Charlton was first with a well arranged bowl of mixed Roses.

CHERRY AND SOFT FRUIT SHOW.

Seldom before has such a grand display of soft fruits, and of Cherries in particular, been staged in London, as was seen on the occasion of the Sixth Cherry and Soft Fruit Show, held under the auspices of the Kent Branch of the National Farmers' Union, at the new Horticultural Hall, in conjunction with the meeting of the Royal Horticultural Society on July 16. Fourteen Challenge Cups, in addition to several pieces of plate and numerous silver egg-cups and egg-spoons, were competed for, and attractive money prizes were also offered. Large numbers of entries were recorded in practically every class, and the general quality of the fruits displayed was very high.

In the classes for single 4-lb. chip baskets of distinct varieties of Cherries, the first prize winners were:—Messrs. F. and T. Neame, Faversham, for Roundell or Bedford Black; Messrs. Smeed, Dean and Co., Ltd., Sittingbourne, for Waterloo, and for Noble; Messrs. Wakeley Bros., Ltd., for any other black variety; Mr. Walter F. Wood, Chekes Court, near Sittingbourne, for Napoleon (the champion basket of Cherries in the show); and for Amber (Kentish Bigarreau); Messrs. G. H. Dean and Co., Ltd., for any other white variety; and Mr. Frank Maylam, Ham Street, Ashford, for any red (sour) variety.

There were eleven grand exhibits in the class for baskets of three distinct black varieties, the first prize being awarded to Mr. J. D. Maxted, Teynham, Sittingbourne; second, Messrs. G. H. Dean and Co., Ltd., while competition was also very keen in the corresponding class for white fruits, the last-named exhibitors securing the premier award with grand fruits of Florence, de Mezel and Napoleon; second, Messrs. Smeed, Dean and Co., Ltd.

Mr. J. D. Maxted was first in the class for a collection of varieties (not exceeding twelve) in 1-lb. punnets, with a fine set, Messrs. G. H. Dean and Co., Ltd., being placed second, and Messrs. W. Brice and Sons, Higham, third.

There were four classes for Gooseberries, and each was well filled, Mr. W. C. Ballard, Strood, was first for one 4-lb. chip basket of any red variety, showing grand fruits of Lancashire Lad; second, Messrs. Smeed, Dean and Co., Ltd., while for one basket of Leveller, Mr. Sydney Wakeley, Rainham, was first, with enormous fruits, Messrs. H. and A. Hales and Mr. W. Alexander being second and third, respectively. For one basket of any green, white or yellow variety, other than Leveller, Mr. G. Setterfield, Ash, near Canterbury, was first, and Messrs. Wakeley Bros., Ltd., second.

Some grand fruits were shown in the class for 1-lb. punnets of not more than four varieties of Gooseberries, Messrs. W. Brice and Sons, Higham, securing the premier award, their varieties being Leveller, Careless, Lancer and Gunner; second, Messrs. Wakeley Bros., Ltd.

Mr. J. F. Foat, Ash, was placed first in the class for a basket of any variety of Red Currants, showing grand fruits of Fay's Prolific; second, Messrs. Wakeley Bros., Ltd., with Daniel's Perfection; while in a similar class for Black Currants, in which there were twenty-one entries, Mr. T. J. Hasell, Bromley Common, who showed the variety Edina, was first; Mr. W. West, Crabwood, near Winchester, with Seabrook's Black, second; and Mr. W. Alexander, Eynsford, with Davidson's Eight, third. Competition was also keen in the Raspberry class, which required 1-lb. punnets of any one variety, Mr. S. Austin Smith being the successful exhibitor, with good fruits of Lloyd George, followed by Messrs. G. H. Dean and Co., Ltd.

In the Tomato class, Messrs. G. Fairs and Son, Kingston-by-Sea, Sussex, were first, with a box of uniform and well-coloured fruits of Edmund's No. 2, Mr. John Buries, Hockley, Essex, who showed good fruits of Wright's A.1., being placed second; while for a standard tray of Cucumbers, one variety, packed as for market, the latter exhibitor was placed first, his variety being Butcher's Improved; Mr. S. Austin Smith was second, showing Butcher's Disease Resister.

For a tray of one dozen Peaches, one variety, packed for market, Messrs. G. Fair and Son were placed first for grand fruits of the new variety Princess Elizabeth, very dark-skinned and of good size and texture; second, Mr. A. T. Goodwin, Roseholme, Maidstone.

There was one class to which amateurs were admitted, for a collection of Cherries and soft fruits grown in the open, but no amateurs exhibited, and the first prize was awarded to Messrs. R. and D. Mitchell, Wateringbury, who showed a splendid collection of Cherries, Raspberries, Gooseberries, Red and Black Currants, and Strawberries.

LONDON AND SOUTH OF ENGLAND PANSY AND VIOLA.

A small show was staged by this Society on July 16, in conjunction with the fortnightly meeting of the Royal Horticultural Society. The exhibits were not numerous, but some very good blooms were shown.

Mr. J. H. Little secured the first prize for three distinct species, and also for three distinct Violettas; while Mr. M. Mitchener, Croydon, was first in the important class for six vases of exhibition Violas, showing good examples of Jack Milner, Essie Johnson, Melcombe Milner, Moseley Ideal, Walter Kaye and Andrew Jameson; second, Mr. C. Luckin, East Grinstead, and third, Mr. R. W. Spicer, Alton, both with good sets.

Mr. M. Mitchener was again successful in the class for three vases of exhibition Violas, distinct, showing good vases of John Adamson, Moseley Ideal and Walter Kaye, Mr. R. W. Spicer and Mr. E. Noble, Ponder's End, being second and third, respectively.

The best single vase of a white self exhibition Viola was staged by Mr. J. H. Little; second, Mr. M. Mitchener, the latter exhibitor securing first place for four pans of exhibition Violas. Mr. M. Mitchener was first for one vase of a white, cream or primrose, edged or banded, exhibition Viola, with good blooms of Mrs. H. J. Milner, cream, edged lavender; and for one vase of a yellow self Viola, showing John Adamson.

For one vase of a yellow-ground, edged or banded, exhibition Viola, Mr. C. Luckin was awarded the first prize, showing, in this instance, the best blooms in the show, and he was also placed first for one vase of a dark self-coloured exhibition Viola, and for one vase of a Fancy or striped exhibition Viola, showing Andrew Jameson in good condition.

Mr. C. G. Clark, Bishop's Stortford, was successful for a single vase of six varieties of exhibition Violas, followed by Mr. H. R. Day, Brentwood, and the former exhibitor also led for a single vase of an exhibition Viola.

For twelve blooms of Fancy Pansies, Mr. R. W. Spicer was awarded the first prize, and he also showed the best set of six blooms.

Mr. T. Philpot led for one pan of a self-coloured bedding Viola, his variety being Archie Grant, and also for one pan of a bicolor bedding Viola, showing good blooms of Mrs. Marrison.

ROYAL HORTICULTURAL.

The following awards have been made to the undermentioned flowers and vegetables by the Council of the Royal Horticultural Society, after trial at Wisley.

Alpine Phloxes.

Awards of Merit.

(7) *Lavinea*, sent by Miss M. C. Taylor, Reigate; (19) *Sprite*, by Messrs. G. Arends, Ronsdorf; and (20) *Seraph*, sent by Messrs. Barr, Ltd., Covent Garden.

Highly Commended.

(15) Moerheimii, sent by Messrs. Bakers, Codsall; (21, 22) Fairy, by Messrs. Bakers and Messrs. Hemsley, Crawley; and (39) atropurpurea, sent by Messrs. Bakers.

Polyanthus.

Award of Merit.

Barrowby Gem, sent by Mrs. MacColl, Harrogate.

Perennial Lupins.

Awards of Merit.

(2) *Edna*, sent by Messrs. W. H. Simpson, Birmingham; (15) *Highlander*, by Messrs. W. H. Simpson; (29, 70) *Northern King*, by Messrs. W. H. Simpson and Messrs. Dickson and Robinson, Manchester; (31) *Exquisite*, by Messrs. W. H. Simpson; and (82) *Northern Fire*, sent by Messrs. Dickson and Robinson.

Highly Commended.

(5, 55) Ada, sent by Messrs. W. H. Simpson and Messrs. Harkness, Bedale; (6) Elizabeth Arden, by Messrs. W. H. Simpson; (21) Saint George, by Messrs. W. H. Simpson; (22) Delight, by Messrs. W. H. Simpson; (30) Emperor, by Messrs. Downham, Calgate; (33) Twilight, by Messrs. van Tubergen, Holland; (38, 76) Northern Lass, by Messrs. W. H. Simpson and Messrs. Dickson and Robinson; (41) Artist, by Messrs. van Tubergen; (45) Victoria, by Messrs. W. H. Simpson; (67) Northern Beauty, by Messrs. Dickson and Robinson; (71) Northern Torchlight, by Messrs. Dickson and Robinson; (89) Taplow Blue, by Messrs. Barr and Sons; and (27) Rosalind, sent by Messrs. W. H. Simpson.

Trollius.

Awards of Merit.

(7, 21) *Goldquelle*, sent by Messrs. B. Ladhams, Southampton, and Messrs. van Tubergen; (9) *Newry Giant*, by Messrs. Ruys, Holland; (16) *asiaticus var. Salamander*, by Messrs. Ruys; (24) *europaeus var. superbus*, by Messrs. Amos Perry, Enfield; (20) *Lightball*, by Messrs. Ruys; and (51) *His Majesty*, sent by Messrs. Ruys.

Highly Commended.

(2, 18) Orange Princess, sent by Messrs. Bakers and Messrs. van Tubergen; (4) Golden Wonder, by Messrs. Ruys; (6) Fire

Globe, by Messrs. Ruys; (10, 12) Orange Globe, by Messrs. B. Ladhams and Messrs. van Tubergen; (14, 25, 57), Etna, by Messrs. B. Ladhams, Messrs. Van Tubergen and Messrs. Ruys; and (44) T. Smith, sent by Messrs. Ruys.

Mossy Saxifrages.

Awards of Merit.

(42) *Bee's Pink*, sent by Messrs. Ruys; and (64) *Triumph*, sent by Messrs. Arends.

Highly Commended.

(25) Mrs. E. Piper, sent by Messrs. R. V. Roger, Pickering.

Commended.

(33) Enchantress, sent by Messrs. Barr and Sons; and (45) Beauty of Ronsdorf, sent by Messrs. Ruys.

Canterbury Bells.

Awards of Merit.

(4) *Single White*, sent by Messrs. Dobbie and Co., Ltd., Edinburgh; (8) *Calycanthema White*, by Messrs. E. Webb and Sons, Wordsley; (38) *Single Mauve*, by Messrs. Hurst and Son, Kelvedon; (32) *Calycanthema Mauve*, by Messrs. Hurst and Son; and (62) *Double Rose Carmine*, sent by Messrs. Haage and Schmidt, Germany.

Highly Commended.

(14) Single Rose, sent by Messrs. E. Webb and Sons; (19, 20) Calycanthema Rose, by Messrs. W. H. Simpson and Messrs. E. Webb and Sons; (36) Single Mauve, by Messrs. Daniels Bros., Norwich; and (63) Double coerulea, sent by Messrs. Haage and Schmidt.

Rhubarb.

Awards of Merit.

(24) *Hawke's Champagne**, sent by Mr. W. Poupart, Walton; and (25) *The Sutton*†, sent by Messrs. Sutton and Sons, Reading.

Highly Commended.

Alike (9, 14) Collis's Seedling,† entered by R.H.S. Gardens; (28) Buck's Early Red,* entered by R.H.S. Gardens; (34) Appleton's Forcing,* sent by Messrs. Appleton, Northwick; (38) Cutbush's Seedling,* sent by Messrs. Cutbush, Barnet; (40) Crimson Queen,* sent by Messrs. J. Kelway and Son, Langport; and (41) The Streeter,† sent by the Hon. Vicary Gibbs, Elstree.

Commended.

(1) Laxton's No. 1, sent by Messrs. Laxton Bros., Bedford.

GUILDFORD GARDENERS'.

This Society, composed of very enthusiastic gardeners—amateur, professional and trade—held its annual exhibition in the grounds of Stoke Park on July 17. The exhibition was a good one, despite the trying conditions imposed upon mid-Surrey gardeners by the long period of dry weather. The weather was brilliant, competition good, and trade displays excellent. As Stoke Park is above Guildford town, the generous hospitality extended by the President, Alderman W. T. Patrick, to the judges, committee and principal exhibitors, and the Councillors and their ladies, was very greatly appreciated.

The Gardeners' Chronicle Silver-gilt Medal, offered for the best non-competitive amateurs' exhibit, was awarded to Mr. A. E. Tylecote, for a fine display of Sweet Peas.

Gold Medals were awarded to Messrs. Spooner (Guildford), for an array of floral designs, Hydrangeas and Gladioli; and to Messrs. Sale and Son, for a glorious exhibit of Roses.

Mr. J. Denyer showed floral designs, and Messrs. Fogwill displayed Sweet Peas and hardy flowers; each received a Silver-gilt Medal.

Silver Medals were awarded to Messrs. Scott, for Carnations; the Godalming Nurseries, for hardy flowers; the Crastock Nurseries, for Roses, and Messrs. Luff and Son, also for Roses.

The best six vases of Carnations were shown by E. L. Louddras, Esq., who had fine examples of White Pearl, Coral Glow, Mary Allwood and Sunset; second, Mr. Coutts. Major H. Howard (gr. Mr. W. H. Cook) led for nine vases of Sweet Peas with a fine set of Pinkie, Fluffy Ruffles, Avalanche, Blue Bird, Warrior, Grenadier and George Shawyer; second, the Beach Hotel (gr. Mr. Wilby), Littlehampton. In a very keen competition, Mrs. Combie (gr. Mr. T. Young) led for a dozen kinds of hardy herbaceous flowers, and contributed goodly sheaves of Heleniums, Delphiniums, Campanula lactiflora, Achillea Eupatorium, Chrysanthemum Lothian Bell and Lilium candidum; second, R. H. Haslam, Esq. (gr. Mr. T. Boole). A Silver Cup accompanies the first prize in this class.

D. R. Lyle, Esq. (gr. Mr. G. A. Thorsworthy), gained first prize for a collection of four kinds of fruits, and W. T. Patrick, Esq. (gr. Mr. Gill), came second. F. F. Smallpiece, Esq. (gr. Mr. W. F. Binfield), had the best collection of choice fruits, showing Black Hamburgh Grapes and Dymond Peaches in excellent condition; second, J. J. Joicey, Esq. (gr. Mr. J. Mackay).

Major Howard showed the best collection of six kinds of vegetables, and was followed closely by Gordon Stewart, Esq. Mr. A. Norman excelled for a display of Roses, and showed Mrs. H. Morse, Captain Harvey Cant, Margaret D. Hamill, Mrs. H. Stevens and Etoile d'Holland, in good form; second, J. G. Gordon, Esq. (gr. Mr. C. Howell). All the foregoing were open classes.

In the division for members only, P. A. Molteno, Esq., won first prizes for Begonias, and Delphiniums; the Hon. Mrs. Abel Smith, for herbaceous flowers, for fruits and vegetables; F. F. Smallpiece, Esq., for annual flowers, and for Phloxes; and J. N. Cross, Esq., for Roses.

General Sir Alfred Edwards, Mr. E. J. Malyon, Miss A. C. Crookenden, Mr. A. G. Scorer, Mr. Bowyer and Mr. Portsmouth were other successful exhibitors.

The cottagers' and allotment holders' classes were well filled, and there was a capital display of Fuchsias grown by the school children of Guildford.

All the arrangements were excellent, and Mr. Pettit is proving a most capable show secretary.

ROYAL CALEDONIAN HORTICULTURAL.

At the recent meeting of this Society there was a general discussion on the subject of Plant Diseases. Mr. J. S. Chisholm produced specimens affected by the more common diseases and suggested remedies. For cluster cup of Gooseberries, he advised picking and burning all affected leaves and fruits, together with good cultivation; spraying for this disease is practically useless. For powdery mildew of Apples (Sphaerotheca Mali) spraying with lime-sulphur is beneficial, but the prompt removal of affected leaves is an essential part of the treatment. For "reversion" of Black Currants no treatment has yet been discovered that will cure it, and the only method of attack so far is to cut out and burn all affected branches. In Raspberries this season, there has appeared what seems to be a disease causing the canes to die off, but this has arisen through the severe frost in February having burst the bark of the canes. In every case strong, healthy shoots are springing up which ought to give a good crop of fruits next year.

The Glasgow City Parks Department exhibited a group of Hydrangeas, Pear Gynt and Pasteur, Cannas and Alonsoa, for which they were awarded a Cultural Certificate. There were also exhibits of Roses by Messrs. Alex. Dickson and Sons, and early Carrots by Mr. W. G. Stott, Murrayfield.

A seedling Dianthus named Royal Stuart, exhibited by Mr. George Stuart, obtained an Award of Merit.

In the competition for two vases of Roses, Mr. R. B. White, Murrayfield, obtained the first prize, and Mr. Francis Glass, Murrayfield, the second. For six Tomatos, Mr. W. McDowell was first, and Mr. W. Crighton, Mortonhall, second.

PROFESSIONAL GARDENERS'.

By the kind invitation of the Mayor and Chairman of the Huddersfield Park Committee, some thirty members recently visited the Huddersfield Parks. Greenhead Park was first visited, where members were met by Councillor Johnson (Deputy Chairman)—the Mayor and Chairman being unavoidably absent—Captain Irons (Superintendent of Parks), and Messrs. Forbes and Martin of Ravensknowle and Beaumont Parks. Councillor Johnson extended a hearty welcome, and the itinerary began.

Greenhead is a fine and imposing park, the sport-loving public being remarkably well catered for, the tennis courts, bowling greens, putting greens, being maintained at a very high standard. The Rose garden was almost at its best, and the carpet bedding was seen to great advantage. The party was next conveyed to Ravensknowle Park, smaller in area, but containing unique features. Several beds of the comparatively rare Pelargonium Black Vesuvius were noted and admired. A very delightful corner devoted to sub-tropical bedding, with Succulent plants and Cacti, was particularly interesting. Beaumont Park was then visited; this is a park unique in its natural formation of, towering rocks and cliff, rock gardens and pools gorges filled with Ferns, and magnificent terraces commanding a grand view of the surrounding hills and dales. The subjects in the greenhouses were particularly well-grown—also stove plants, which are now becoming rare.

By the kindness and hospitality of the Parks Committee, tea was provided at the Park Café. Mr. J. T. McCormack (President) proposed a hearty vote of thanks to the Mayor, Chairman, Deputy Chairman, Captain Irons, Messrs. Forbes and Martin for their kindness and hospitality. Mr. Tully (Batley Parks) seconded the vote in suitable terms, and was supported by Mr. G. Reid, Organising Secretary.

The party then repaired to the headquarters of the Huddersfield branch of the P.G.A., where a profitable and pleasant evening was spent, new members being elected, and business discussed.

Obituary.

George Burrell.—We regret to announce the death, last week, from pneumonia, of Mr. George Burrell, Parks Superintendent to the Beddington and Wallington Urban District Council. Mr. Burrell, who held a similar appointment at Ashington for many years before going to Wallington in June, 1928, was a keen horticulturist, and made great improvements in the parks under his control during the short time he was at Wallington. He was very popular with the members of clubs and residents using the grounds and gained the respect and confidence of the members and officials of the Council.

Mr. Funatsu.—The greatest of all Cherry lovers has passed away. My last Japanese mail brought me tidings that my old friend, Mr. Funatsu, had recently died. I believe he devoted most of his life to the study and cult of this tree—to talk to him, it almost seemed as though his very soul was steeped in the beauty of their blossoms. His delightful personality and undisguised enthusiasm had an almost irresistible charm. Mr. Hayashi, the Secretary of the Japanese Cherry Society, pays just tribute to his late colleague:—"Mr. Funatsu's death is an irreparable loss to the Sakura-no-Kwai (the Japanese Cherry Society). We had hoped to do many things—among them, the making of a Cherry park. All is now over. There is no one left in Japan to take his place." A portrait of Mr. Funatsu and a brief appreciation appeared in *The Gardeners' Chronicle* of November, 20, 1926. *Collingwood Ingram.*

---

* = Award recommended for earliness.
† = Award recommended as a late variety.

R. Jones.—A wide circle of friends in the horticultural world will be deeply grieved to hear of the death of Mr. Richard Jones, which occurred at a nursing home at Leamington on the 13th instant. Mr. Jones, who was sixty-seven years of age, served as a journeyman in such famous gardens as those of Penrhyn Castle, Floors Castle and Dover House. Thirty-seven years ago he was appointed gardener to the late C. A. Smith-Ryland, Esq., Barford Hill, near Warwick, and sixteen years later was promoted to the post of estate agent, a position he held up to the time of his death. Mr. Jones, who endeared himself to the hearts of all he came in contact with, took a leading part in the activities of village life, and his remains were laid to rest amid signs of the deepest sympathy, in the cemetery at Barford, on the 16th instant. At one time Mr. Jones was a prominent exhibitor of Chrysanthemums at Birmingham and other midland shows, where his exhibits won high honours in severe competition. As a staunch friend ever ready to help forward any good cause, or to extend a helping hand to the struggling, he will be greatly missed; and as a fine cultivator and enthusiastic horticulturist, his memory will be esteemed by a large circle of gardeners.

ANSWERS TO CORRESPONDENTS.

BRASSICAS ATTACKED BY CABBAGE FLY.—*H. W. J.* The plants of Cauliflower and Brussels Sprouts are attacked by the larvae of the Cabbage fly, Chortophila brassicae. This pest may be defeated by the use of tarred felt discs, which are placed around the stems of the plants when planting them out from the seed beds. The result is satisfactory, provided the soil is in fine tilth so that the collar lies flat on the surface of the soil. Another method is to sprinkle naphthalene (Grade 16) around the plants, at the rate of a quarter-of-an-ounce per plant. Three applications should be made at intervals of seven days.

CLASSIFICATION OF MUSHROOMS.—*A. P.* Yes, the Mushroom is certainly classed as a vegetable.

GLOXINIA DISEASED AND TOMATO LEAF SPOTTED. *T. J. C.* Both plants were scorched with sulphur fumes. The brown mottling on the Gloxinia leaves was due to the presence of immature thrips, which may be seen along the midrib.

NAMES OF PLANTS.—*P. C.* 1, Oenothera Fraseri; 2, Lysimachia verticillata; 3, Campanula lactiflora (dark form); 4, Escallonia langleyensis; 5, Cistus ladaniferus; 6, Spiraea Douglasii; 7, Erigeron speciosa var.—*G.* 1, Lychnis coronaria; 2, Campanula glomerata; 3, Lathyrus grandiflora; 4, Tradescantia virginica; 5, Paeonia officinalis var.; 6, probably a Hieracium; 7, Eryngium Violetta; 9, Potentilla hybrid, badly damaged; 13, Lilium tigrinum. The remainder were lost or badly damaged in the post.

TOMATOS FAILING TO COLOUR.—*F. G. P.* The Tomatos are quite healthy. The lack of colour is due to shortage of potash in the soil. Apply a light dressing of nitrate of potash and water it in.

TREATMENT OF CRASSULAS AFTER FLOWERING.—*B. B.* The plant you sent was Crassula coccinea. After flowering is over, cut back the plant, and increase it by cuttings.

VINES UNHEALTHY.—*J. H. and A. M.* Your Vines are suffering from scalding. This may arise from insufficient ventilation or, more often, from failure to open the top ventilators sufficiently early in the morning. By ventilating the house very early the fruits and leaves become drier than they would otherwise, before the sun is very powerful, and this is necessary in order to prevent scalding.

REMARKS.—Conditions are very unsatisfactory, the present weather being unfavourable for the distribution of cut blooms, therefore prices in general are very low; the heavy supplies of Carnations and Roses and all outdoor blooms are too large for present requirements. The newest arrival in this department is double white Gypsophila paniculata and the variety Bristol Fairy, Statice latifolia and S. incana. A few more bronze and yellow Chrysanthemums have been offered, but there is very little demand for these at present. In the plant department trade is somewhat dull. There is little demand for Ferns and other foliage plants. The most attractive lines in flowering plants are blue and pink Hydrangeas in various sizes, Marguerites, Viscarias, Calendulas and some very fine giant Daisies in pots. Hydrangea paniculata var. grandiflora is the newest arrival in this department.

REMARKS.—Although trade does not seem particularly active there is a very large volume of produce passing through the market. Hothouse Grapes are selling moderately well, Peaches, Nectarines and Figs are quoted lower, the highest-class trade being not quite so brisk as of late. Raspberries have been abundant and cheap. Melons are also plentiful, but figures in that section are being fairly well maintained. Black Currants have been, and still are, a weak department, and although prices are low there is no life in the demand. Red Currants remain in steady request. Cherries have sold well, practically all varieties and grades going out at prices which are more or less satisfactory to the growers. Gooseberries of the Leveller type are in ample supply, and prices are not too bad. Tomato supplies are heavy and prices inclined to be on the low side. Cucumbers remain steady in supply and demand; Mushrooms are not plentiful, the recent hot weather having more or less exhausted the beds. Vegetables of practically all kinds have been a bad trade, and Cauliflowers in particular are not wanted. The warm weather is probably making itself felt in the kitchen so far as cooking is concerned. Salads are a brisk trade. The Potato market is quiet.

GLASGOW.

The feature of the cut flower market last week was the abundant daily supply of Carnations from English growers, and the low prices that ranged from 8d. to 1s. per dozen. Depression, however, was general and acute. Irises were worth from 1d. to 4d. for 6's; Roses, 6d. to 1s. 6d. per dozen; Sweet Peas, 1d. to 6d. per bunch; Gypsophila, ½d. to 3d.; Calendula, Pyrethrum and Sweet Williams, 2d. to 3d.; Marguerites, 1½d.; Pinks, 1d. to 2d.; Scabious, 3d. to 5d.; Stocks, 2d. to 4d.; Gaillardias, 2d.; Liliums, 1s. 9d. to 2s. 6d.; and Gladioli, small, 4d. to 5d. for 6's; and large, 1s. to 1s. 6d.

Fruit prices showed irregular movements. Strawberries were scarce and realised from 10d. to 1s. 9d. per lb. for table qualities, and 7d. to 9d. for preserving; while English Black Currants were a glut in the market and were difficult to move at 5d. to 6d. per lb.; Scotch-grown supplies averaged 8d.; Red Currants fluctuated between 5d. and 6d. per lb.; Raspberries, 8d. to 1s. 2d.; green Gooseberries, 2d.; red, 1½d.; sulphur, 6s. to 7s. per sieve; Muscat Grapes, 3s. per lb.; Peaches, 7d. to 1s. 2d. each; Melons, 6s. each; Canteloupes, 2s. each; Gages, 18s. per sieve; Plums (Californian), 16s. per tray; Apricots, 8s. 6d. to 9s. (20 lbs.); Grape Fruits, 35s. per ase; New Zealand Apples, 22s. to 24s.; Californian Oranges, 22s. to 26s.

Most vegetables were cheaper. Cucumbers sold from 3s. to 8s. per dozen; Lettuces, 6d. to 1s.; Scotch Cauliflowers, 5s. to 6s. 6d.; Peas, 5s. to 6s. 6d. per pot of 40 lbs.; Beans, 1s. to 1s. 2d. per lb.; Mushrooms, 2s. French Carrots and Turnips, 10d. to 1s. per bunch; home-grown Turnips, 3d. to 4d.

WEATHER IN JUNE.

Until within a few days of its close, the predominating winds during June were westerly. The weather was therefore rather cool, although quite a considerable amount of sunshine was experienced. The principal feature, however, was a continuance of the deficiency of rainfall, the month forming the seventh consecutive one in which the normal precipitation was not reached. From 8 a.m. to 8 p.m. (G.M.T.) hardly any rain was recorded during June, and there was very little more in the evenings. The only wet period was from 1 a.m. to 7 a.m. The month's mean temperature was 56°, or half-a-degree below the average. There were 265 hours of bright sunshine, or 53 hours more than the normal duration. This compared very favourably with some of the sunniest south coast resorts; at Worthing only 237 hours were recorded. Rain fell on 12 days, or merely one fewer than usual; but the total amounted to no more than 1·22 inches, that being 0·94 inch below the average. At Birkdale, however, 1·57 inch was measured. Distant thunder was heard on the afternoons of the 8th and 14th. *Joseph Baxendell, The Fernley Observatory, Southport.*

Flower Shows and other Rural Amenities.

Whether there are or are not too many large horticultural exhibitions held annually throughout the country is at present a debatable point among exhibitors, and especially among trade exhibitors. The competition for space for trade displays at these leading shows is severe, and such displays are necessarily costly ; the principal nurserymen and seedsmen make larger and more effective displays year by year, consequently the traders with fewer facilities and limited financial resources have small chance to obtain the highest or even other medal rewards offered. In this connection the line taken by the Guildford Gardeners' Association is worth consideration. The Committee offers a certain number of medals for trade displays, but in two series, one set for exhibits over fifteen feet in length, and one for groups exceeding that space ; this allows all the trade exhibitors a fair chance of securing an award. But whatever the feeling with regard to the increasing number of big shows, every one will agree with the Minister of Agriculture that village shows are acquiring added importance and becoming part of the amenities of rural life. He might have added that village shows are of great importance horticulturally, because of the incentive they afford and the encouragement they provide for local growers—amateur and professional—to excel in the production of garden produce. The higher the general level of skilled cultivation is raised, the better for the country at large. When opening a flower show at Upshire, Waltham Abbey, Mr. Noel Buxton referred to the efforts of the National Gardens Guild, of which the Queen is the Patroness, to bring beauty and colour into the towns. Modern activities, motoring and so forth, have planted many hideous features on the countryside. Petrol stations raise their pale, forbidding heads on red posts, and there are other harsh features along our modern roadways. The Gardens Guild, which is now extending its activities into the country villages, is doing a great service in promoting competitions aiming at beautifying the countryside, while daily papers encourage gardening in large cities, such as London and Sheffield, and good work is being done by Road Beautifying Associations. Horticulture has its more material aspect—the growing of fruits and vegetables—and here the Ministry of Agriculture plays a notable part in improving the technique of cultivation. Mr. Buxton urged local authorities to provide model allotments and demonstration fruit and vegetable plots, and stated that the Ministry was already helping local Councils with money to provide these demonstration allotments. The Lea Valley, in which Upshire Show was held, contains an extensive glasshouse industry, the annual value of the output of Tomatos and Cucumbers alone being over £2,000,000. The Ministry assists research in glasshouse problems by a grant of over £3,500 a year to the Cheshunt Research Station. Mr. Buxton added that he was eager also to promote village amenities, and the Ministry of Agriculture, through the Development Fund, was ready to make grants for the promotion of village halls. Nothing could be more conducive to happier conditions than a place where villagers and the country people around could meet together. The Rural Industries Bureau, also assisted by Government grants, helps to promote handicrafts, such as basket-making, and the Minister commended these activities for the improvement of social amenities to the notice of every village.

Teddington Lock Garden.—Many of the lock-keepers on the Thames are keen gardeners, and their efforts are encouraged by the Thames Conservancy Board, which offers prizes for the best efforts. This year the Sir Reginald Hanson Challenge Cup has been awarded to Mr. A. E. Allen for the charming garden he has tended so skilfully at Teddington Lock, just above Richmond.

The Foundling Hospital Site.—On Tuesday, August 6, a large holiday play centre, organised by the Children's Play Centres Committee, will be opened by permission of Lord Rothermere on the Foundling Hospital Site, for the benefit of the children in the densely populated areas east and south of the site. Throughout August the old grass lawns, under the ancient Plane trees, will be open as a playground for the children for seven hours each day, and during September they will be admitted after school hours. A play-centre for " toddlers " has been organised in another part of the grounds.

Sutton Bonington Horticultural Conference.—At a recent Conference of Horticultural Organisers and Inspectors, held at the Midland Agricultural and Dairy College, Sutton Bonington, Loughborough, Mr. R. V. Harris, of the East Malling Experimental Station, gave a very interesting account of the lines of investigation pursued at that station, with special reference to their practical application to commercial fruit production. The speaker first dealt with Dieback of Stone Fruit Trees, particularly of Plums and Cherries. These diebacks are not influenced by soil factors nor by the stocks, but different varieties show different susceptibilities. Victoria Plum and Giant Prune are very subject to the disease, which is most serious on young trees up to five years old. It has been shown that the disease can by induced by inoculations of bacteria obtained from diseased plants. In Cherries, dieback is not so serious as in Plums, as its effect is usually limited to portions of the trees. Mr. Harris then explained the methods of spraying to be adopted for control of Apple Scab and mildew. The use of lime-sulphur was advocated. The difference in susceptibility according to the different stocks was noted, and the different effects of the spray on such Apples as Cox's Orange Pippin and Stirling Castle was emphasised, after which he dealt with the various Raspberry diseases. He gave full details of the serious disease known as Cane Spot, and showed how spraying with Bordeaux mixture will reduce the damage. He pointed out how lime-sulphur appeared to control the disease, but, unfortunately, injured the plants for future cropping. Mr. Harris stated he considered the Mosaic Disease the most serious menace to the Raspberry-growing industry. The disease was little understood yet. It had been shown that it was transmissible by grafting and different varieties exhibited varying susceptibilities to the disease. Laxton's Abundance was virtually immune, and Bath's Prolific very resistant. Red Cross, Beaumforth's Seedling and Pyne's Royal do not suffer much, but Superlative and Norwich Market are very susceptible. A very interesting discussion followed, and Mr. Harris was heartily thanked for his most interesting and valuable paper, which was illustrated throughout with lantern slides.

Recreation Grounds for Tilbury.—On July 27, Mr. W. L. Tourle, Clerk of the Works of the R. E. War Department, Chatham, formally handed over to the Tilbury Urban Council the lease of a portion of the lands and premises of the old Tilbury Fort situated outside the actually fortified area. It is the intention of the Council to use the acquired area for recreation purposes. A promenade, with a bandstand, will be constructed, and a field will be set aside as a playground, while it is proposed to clean out a portion of the moat and to convert it into a bathing pool and model yacht pond.

Edinburgh v. Kew.—An interesting event took place on Kew Green on Wednesday, July 24, when teams from Kew and Edinburgh Royal Botanic Gardens met to play a friendly cricket match, which, after a keen struggle, terminated in favour of Edinburgh. This may lead to future matches between these famous botanic gardens, and further cement the bonds of friendship which at all times have existed between these establishments.

Foremarke Cup for Gladioli.—The annual competition for the Foremarke Challenge Cup for Gladioli will take place this year at the Royal Horticultural Society's fortnightly show in the new hall, Greycoat Street, Westminster, on August 13. The Cup is offered for the best twenty spikes of named Gladioli in not fewer than ten varieties. Not more than two spikes of any one variety may be shown. The competition is open to both amateur and trade growers. Entry forms may be had on application to the Secretary, Royal Horticultural Society, Vincent Square, Westminster, S.W.1. Entries close after the first post on Wednesday, August 7.

Arrowe Park, Birkenhead.—Birkenhead's spacious open space, Arrowe Park, is at present the home of fifty thousand Boy Scouts, representing forty-two nations. The park is well-wooded, and an ideal setting for the great international Jamboree. It has been stated that Arrowe Park is the largest open public space in the country, but we are doubtful whether it is entitled to this distinction. Perhaps our readers may help us to discover which is the largest public open space.

Strawberry Crop Failure in North-east Scotland.—The bright prospects engendered some weeks ago of a bumper Strawberry crop have failed to materialise, and the market gardeners in the north-east of Scotland are faced with heavy financial loss in connection with the crop.

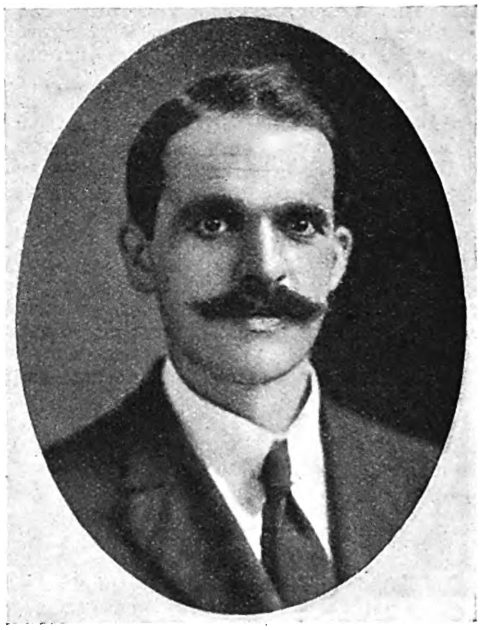
The failure is not due to the disease reported from Clydeside and Lanarkshire, but to the extreme drought and brilliant sunshine which has prevailed for weeks past. Whole areas under Strawberries have been turned completely brown, leaving little to show for the time and money expended. It is computed that where a hundredweight of Strawberries was gathered last year there will this season be only a few pounds. This is all the more tantalising when it is remembered that in late spring and early summer the plants looked wonderfully well and bloomed profusely. All the conditions then pointed to a successful season, but it has turned out one of the poorest for many years Coming late, as they do compared with the English crop, Scottish Strawberries are always sure of a good market in the south. Happily, much more favourable reports have to be given of the Raspberry and Black Currant crops. These are looking exceedingly well, and provided nothing untoward occurs, should give excellent returns.

Summer Meeting of the Royal English Arboricultural Society.—An interesting programme has been arranged for the summer meeting of the above Society. The headquarters for the meeting will be at Sheffield, and visits will be made to various estates in Lincolnshire and Yorkshire during the week commencing August 26. The Manby Estate will be visited on August 27, and the Brocklesby Park Estate on August 28, both of these being owned by the Earl of Yarborough. The Wentworth Estate and the Doncaster Estate, owned by Earl Fitzwilliam, will be visited on August 29 and 30, respectively. The tree-felling competition, confined to members of the Society in Lincolnshire, Yorkshire, Nottinghamshire and Rutland, or men regularly employed by members in these counties, will be held in Brocklesby Park on the afternoon of August 28, and the Annual General Meeting of the Society will be held at 9 p.m. on the same day, at the Grand Hotel, Sheffield.

Control of the Codlin Moth by Parasites.—It is reported in a recently issued *Daily Science News Bulletin*, published by Science Service, Washington, D.C., that an attempt is being made to control the Codlin Moth in the Walnut groves of California with the aid of a minute Chalcid egg-parasite, by adopting the mass-rearing and liberation of the parasite (Trichogramma minutum). The Chalcid is known to attack a great variety of insect eggs, and those of the Grain Moth are stated to have proved specially suitable for breeding purposes. It is stated that, in a building with a floor space twenty-five feet by thirty-six feet, one million parasites are reared per day. Packages containing 100,000 parasitised eggs of the Grain Moth are sent by mail to growers troubled with the Codlin Moth, and when the parasites emerge from these eggs they are released in the Walnut groves, where they soon seek out the eggs of the Codlin Moth. It is hoped that by raising the Trichogramma population in the Codlin Moth infested areas, the wholesale destruction of the eggs of the latter will result.

Cliveden Reach.—We learn that Lord Astor has offered to preserve, as a private open space, certain lands at Cliveden, by the Thames, above Boulter's Lock. This is being done in conjunction with the Town Planning Committee of the Eton Rural District Council, and will ensure the preservation of the beauties of one of the loveliest spots in the Thames valley.

"The British Fern Gazette."—Special features in the final part (No. 12) of Vol. V of *The British Fern Gazette;* which is edited by F. W. Stansfield, M.D., F.L.S., and published by the British Pteridological Society, are a frontispiece of an exceedingly fine frond of Polystichum angulare divisilbum plumosum deltoideum, which was raised by the late Mr. H. Stansfield; a review by Mr. S. P. Rowlands of Professor Bower's Presidential Address to the Yorkshire Naturalists' Union, at York, entitled "The Evolutionary Relations of the British Ferns"; and an account by Mr. E. A. Elliott of the Fern planting that has been carried out at the Staffordshire Nature Reserve. This reserve is at Hawksmoor and lies on high, well-wooded and; its superficial area is given as 200 acres, but taking into account the valleys and hills, the area is stated to more readily approximate 400 acres. Some thirty species of Ferns have been recorded in Staffordshire, but the majority of these are now rare, and some extinct, and in September, 1928, a small party, including Mr. Elliott, met at the reserve and planted many of these species. The various Ferns planted, and their positions, are recorded in Mr. Elliott's interesting account, and the hope is expressed that they will escape the vandals, who have already appeared on the scene.



MR. F. W. MILES.

Mr. F. W. Miles.—The Horticultural Lecturer and School Garden Organiser for the County of Hertfordshire is Mr. F. W. Miles, who had a long and varied horticultural experience before taking up his present duties in 1919. He commenced his gardening career at Kelston Park, Bath, in the gardens of the late Major-General Inigo Jones, and afterwards worked for two years in the pleasure grounds at Camerton Court, Somerset, followed by two years as fruit journeyman at Latimer House, Chesham, Bucks. For one year he was plant journeyman at Vale Royal Abbey, Northwich, and then proceeded to Stubbins House Gardens, Maidenhead. Subsequently he was appointed gardener at Ware Park, Ware, Hertfordshire, and held that position for five years. His next appointment was that of Horticultural Superintendent of the Y.M.C.A. Training Centres for Discharged Soldiers and Sailors, and during eighteen months' tenure of this post arranged displays of ex-Servicemen's garden produce at the Free Trade Hall, Manchester; St. George's Hall, Liverpool; Winter Gardens, Blackpool, etc. In 1919, he obtained his present position. In 1926, when the Bath and West and Southern Counties' Show was held at Watford, he superintended the making of a model school garden, a quarter-of-an-acre in extent. The garden was made in ten weeks, and when the exhibition opened it attracted much attention, containing, as it did, vegetables, fruits, flowers, experimental and demonstration plots, together with an up-to-date meteorological station. While in charge of the school garden exhibit at the recent Royal Jubilee Show of the Hertfordshire Agricultural Society at Hatfield Park, he had the honour of being presented to their Royal Highnesses the Duke and Duchess of York. In 1927, Mr. Miles took a Rural Science course at Homerton College, Cambridge. For six years he was Technical Secretary of the St. Stephens (St. Albans) Society, and for two years Show Secretary of the Watford and Home Counties Society, and this year acted as the first Press Secretary of that young but vigorous organisation. Mr. Miles has broadcasted practical gardening talks on six occasions from 2 L O and for many years has written gardening articles for the technical and lay press, contributed to *Black's Gardening Dictionary* and *The Complete Amateur Gardener*. He is also the author of *Jottings from a Gardener's Notebook*, and *Gardening in Practice and Theory.*

National Institute of Agricultural Botany.—At the eighth annual general meeting of Fellows of the National Institute of Agricultural Botany, at Cambridge, on July 26, the Chairman of the Council, Dr. Beaven, reviewed in turn the principal activities of the Institute and their development in the past year. Two important branches of the work, the official seed-testing station, and the Wart Disease of Potatos immunity trials, are delegated to the Institute by the Ministry of Agriculture, and these functions are supplemented by cognate investigations into germination problems, Potato virus diseases and the yield and maturity of Potato varieties. The Potato Synonym Committee, of which Dr. Salaman is the Chairman, had within the last year been able to report a substantial improvement in the nomenclature of Potatos; the Council hoped to win the co-operation of seedsmen in extending this work to cereals in the near future. This would be undertaken by the Crop Improvement Branch as a part of its main function of sorting the good from the bad among old and new varieties of farm crops, and so helping each farmer to choose the variety which would best suit his particular requirements. Dr. Beaven referred to the encouragement offered in the last century by the Royal Agricultural Society to plant breeders and, after tracing the relationship between animal and plant breeding and the influence of Mendel's work, pointed out that field trials of the kind undertaken by the Institute would be needed for many a year to come. The difficulty of the task and the value of the results were alike illustrated by the series of Barley trials completed in the past year. Two varieties raised by systematic methods of plant breeding had been shown to be generally and significantly more profitable to farmers than any others, and records collected independently by the Official Seed Testing Station and the Essex County Farmers' Union not only confirmed this conclusion but showed that these two varieties are now grown more widely than any others. The study by competent critics of these and the similar results now being obtained at the Institute would win for it the support of agriculturists which alone could make effective its motto—"Better Seeds, Better Crops."

Scottish Sweet Pea Trials, 1930.—The Committee of the Scottish National Sweet Pea, Rose and Carnation Society has decided to continue the trials of Sweet Peas, not in commerce, in 1930. Twenty-five seeds of each variety must reach the Secretary, Mr. John Smellie, Westwood Cottage, Helensburgh, Dumbartonshire, not later than the last week of September, so that all may be sown on October 1. Five shillings for each variety must be sent along with the seeds.

Birmingham and Midland Counties Gardeners' Mutual Improvement Association.—This Association was established in 1880, with the late Sir Thomas Martineau as President, "for the promotion and advancement of the Science and Practice of Horticulture, by holding periodical meetings, at which essays and lectures shall be delivered and discussions initiated on all subjects connected therewith, and by forming a library suitable for the general information and reference of members. That the members shall consist of persons who are professional gardeners, under-gardeners, amateurs, nurserymen and seedsmen." The Association has kept true to its purpose and is to-day one of the largest in the country. Lectures are arranged fortnightly at the Chamber of Commerce during the autumn and spring months, in accordance with the original rules and regulations. Summer outings and rambles of an educational character are arranged to readily accessible places of interest. The summer visits for 1929 were arranged as follows:—Monday, May 27: The Grove, Harborne, by kind permission of the Lord Mayor and Lady Mayoress of Birmingham; Saturday, June 22: Primrose Hill, Selly Oak, by kind permission of Mr. and Mrs. George Cadbury; Monday, July 15: Warley Park and Abbey, Birmingham City Corporation; and Saturday, July 27: Annual Outing, by kind permission of H.M. The King, to visit the State Apartments, Windsor, and the Royal Gardens, Frogmore. The Rt. Hon. The Lord Mayor of Birmingham, is President for the present year.

Legacies to Gardeners.—The late Dame Jemima Church, of Shelsey, Kew Gardens, who died on May 8, 1929, left £200 and one year's wages to her gardener, Mr. Goodchild.—The late Mrs. Caroline Tremlett, of Highlands, Exeter, who died on April 21, 1929, left £100 to her gardener, Mr. Thomas White, and £50 to her under-gardener, Mr. Francis Bert Cowler, if in her service at her death.—The late Mr. John Burnup, of Brantwood, Gosforth, Northumberland, who died on May 2, 1929, left £80 to his gardener, Mr. Thomas Matthewson, if still in his employ and not under notice.—The late Mr. Henry Alexander Latham, of Lyndhurst, Childer Thornton, Chester, who died on January 29, 1929, left £75 to Mr. William Hill, and £50 to Mr. Samuel Davies, his gardeners, if still in his service.—The late Mr. Walter Freire Marreco, of Northumberland Street, W.C., who died on May 10, left an annuity of £20 to his gardener, Mr. George Francis Biles.—The late Mrs. Mary Ann Penelope Laurence, of York Terrace, Regent's Park, who died on April 23, 1929, left £52 per annum to Mrs. Mary Ridgewell, widow of her late gardener.

New Seedling Violas.—At a meeting of the Scottish Pansy and Viola Association, held at Glasgow on July 27, Certificates of Merit were awarded to Viola Ann Walker, a cream ground variety edged with lavender raised by Mr. Quintin McFadyen, Carluke; and Isa Muir, a deep canary-yellow Viola, edged with lavender, grown by Mr. David Stevenson, Burnbank.

Stachys tuberifera in Flower.—Miss D. H. Moutray Read informs us that Stachys tuberifera is flowering freely this year in her garden in Sussex. In *The Vegetable Garden*, translated from the French by MM. Vilmorin-Andrieux et Cie, by Mr. W. Robinson, it is stated that the Chinese Artichoke (Stachys tuberifera) seldom flowers "in European climates." The hot, dry weather experienced of late has evidently encouraged it to flower in this country.

Berry-bearing Honeysuckles.—The current issue of the *Bulletin* of the Arnold Arboretum, Harvard University, contains an illustration of fruiting growths of Lonicera bella, and a statement that "L. tatarica and its several forms and hybrids are now (July 15) laden with ripe fruits. These old-fashioned bush Honeysuckles are still among the most useful of the larger shrubs for parks and gardens in the colder parts of this country and Canada. Natives of northern Asia, they are accustomed to a rigorous climate and given plenty of room they will make bushes from fifteen to eighteen feet tall and from twenty-five to thirty feet in diameter, with ascending and spreading branches, forming a round-topped mass. The flowers, white, yellowish, or pink, are freely produced in the early spring and now at high summer the branches are weighted down with ripe berries. In the typical L. tatarica the fruit is red; in the variety lutea, it is orange and translucent. There are several hybrids of which L. tatarica is part parent, all of them excellent shrubs, but none is better than L. bella, which bears enormous quantities of rich crimson berries. These bush Honeysuckles are good-natured plants, but like other shrubs, they respond to liberal treatment. Given a good loamy soil, a position where their roots can be plentifully supplied with water and abundant space in which to develop, they will be objects of beauty decade upon decade. The only pruning necessary is from time to time to remove old and worn-out stems. They enjoy wind and sun, and winter cold never injures them."

Appointments for the Ensuing Week.—Monday, August 5: Bletchley and District Horticultural Society's Summer Show; King's Lynn Horticultural Society's Exhibition; Pershore and District Horticultural Society's Exhibition; Wadhurst and Ticehurst Flower Show and Sports. Tuesday, August 6: Royal Caledonian Horticultural Society's meeting; Abbey Park, Leicester, Flower Show (two days). Wednesday, August 7: National Carnation and Picotee Society's meeting; Rotherham and District Horticultural and Chrysanthemum Society's meeting; King's Walden Bury Horticultural Society's Exhibition; Royal Welsh Agricultural Society's Exhibition (three days); Scottish National Sweet Pea, Rose and Carnation Society's Exhibition (two days); Royal Dublin Society's Horse Show (three days), with Royal Horticultural and Arboricultural Society of Ireland; Gainsborough Allotment Holders' meeting; Northampton Municipal Horticultural Society's Fête (two days); Thursday, August 8: Bakewell Farmers' Club and Horticultural Society's Show. Saturday, August 10: Charfield Fête and Flower Show; Leeds Paxton Society's Open Exhibition night; National Carnation and Picotee Society (Northern Section) Annual Exhibition.

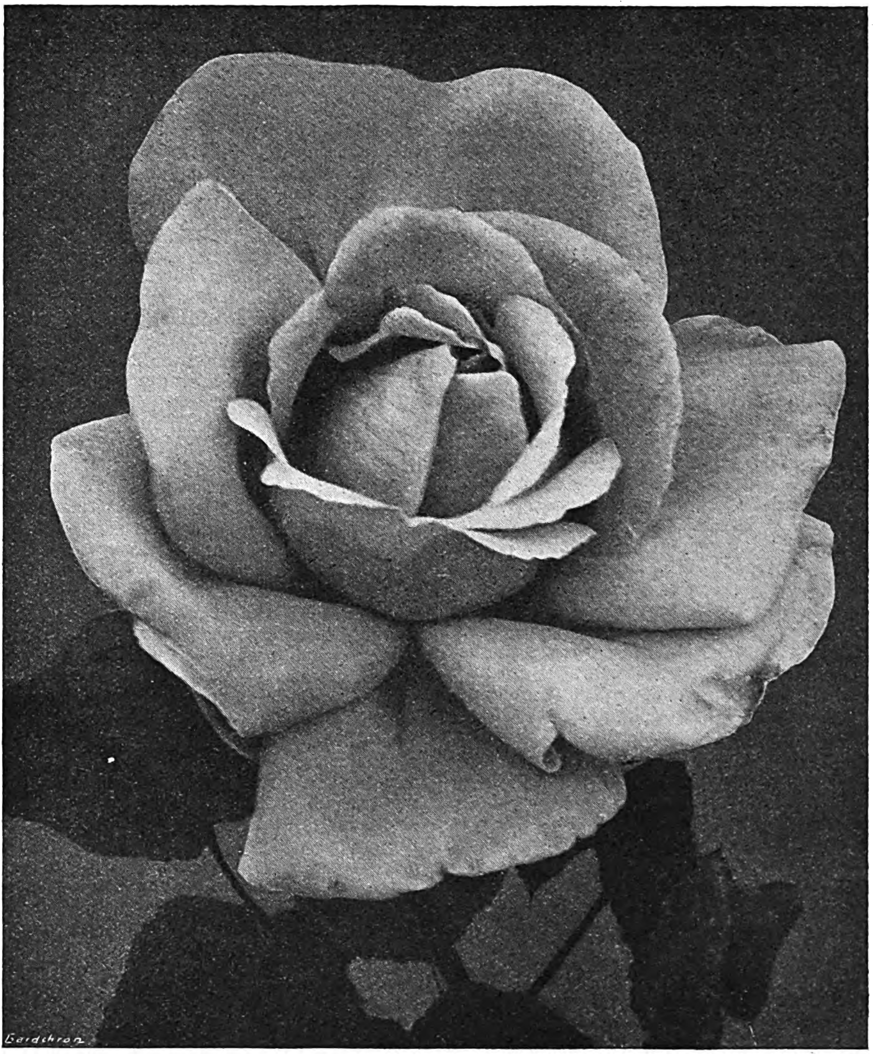


FIG. 37.—ROSE JAMES REA.

N.R.S. Gold Medal, Hereford, July 10. Flowers deep rose. Shown by Messrs. S. McGredy and Son.

(see p. 55.)

"Gardeners' Chronicle" Seventy-five Years Ago.—*Underhill's "Sir Harry" Strawberry*,—"I recommended," says Mr. Beaton, "two sorts of the Strawberries exhibited at the last Chiswick fête, to my late worthy employers, Sir William and Lady Middleton, as most useful in the dessert, but whether or not they are of good flavour is more than I know; the kinds were the Bicton White Pine, a large, white berry, that will make a most useful change in a dessert for great or small parties, and a very dark one named Sir Harry. This last was sent by Mr. Richard Underhill, of Edgbaston, near Birmingham." Having for many years had much experience, and taken great interest in the cultivation of fruit, I called upon the gentleman just mentioned for the purpose of making more particular inquiries respecting his seedling, and possessing myself of that information as to flavour, etc., which Mr. Beaton could not give. Mr. Underhill politely invited me to walk through and inspect his beds, when I was perfectly astonished at the enormous size and deep colour of the fruit, combined with the excessive cropping of the plant. I then tested the flavour with Keen's Seedling and British Queen, both equally well ripened, when the superiority of Sir Harry to either was at once so evident that I pronounce it the most exquisitely flavoured berry I have ever tasted. It is both firm and juicy, and carried its rich red colour entirely through it. The other distinguishing characteristics of the plant are these—its leaves are few, and it spreads its bearing branches out so wide as to thoroughly expose the fruit to the full influence of sun and air.—*James Boucher (formerly Gardener to the Lady Olivia B. Sparrow), King's Heath, Worcestershire. Gard. Chron., August 5 1854.*

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Manchester.

Scale Insects.—These are nearly always present on some Orchids, although, perhaps, not quite so numerous just now as when drier conditions in the houses favour their increase. The bases of pseudo-bulbs and rhizomes are favourite grounds for them, from which they soon spread over the plants and do considerable damage. They should be removed by careful sponging so soon as detected.

Cypripediums.—The elegant flowered, dwarf-growing, succulent-leaved Cypripediums, which include C. bellatulum in variety, C. niveum, C. Godefroyae and its beautiful variety leucochilum, C. concolor, and the many hybrids derived from these, chiefly produce their handsome flowers during the spring and early summer months, and should receive attention with regard to repotting, etc., after the flowering period. Now is a good time to repot any that require fresh soil or larger receptacles. Care should be taken when disturbing the fleshy roots not to damage them; if the roots are healthy and vigorous, the least disturbance given, the sooner will the plants become established, provided the old, sour compost can be shaken out. It is advisable to allow the soil to become fairly dry before turning the plants out. Good drainage is essential, and as these are lime-loving subjects, limestone chips should be used largely in the drainage and also incorporated in the soil, which may consist of equal parts of good fibrous loam and finely cut fibre, although this should be pressed firmly among the roots; ample quantities of limestone chips and crushed crocks should be added in order to keep the soil porous so as to allow the water to pass away quickly. These Cypripediums require rather drier treatment than the green-leaved Cypripediums, especially in the winter time, therefore the growths should be kept well above the soil and moisture should not be allowed to collect in the centre of the growths, while the compost should become dry between each application of water. The plants thrive well when grown in a light position near the glass, at the warm end of the intermediate house, with humid surroundings, and shaded from strong, direct sunshine. During the winter, much drier conditions, both atmospheric and at the roots, should be maintained.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Effects of the Drought.—The rainfall during the past seven months has been extremely low, and has had very serious effects in many gardens about here, while it has also been the cause of much loss to growers of Raspberries and other fruit crops. Any rain that fell during the past three or four months was accompanied, or followed, by strong winds that soon dried up the surface soil to a marked degree, and in gardens the effects of the long-continued drought are being experienced severely. It is in a season like the present one that the inadequacy of the water supply is felt most sorely, for the fruits and vegetables, in most cases, fail to attain their fullest development owing to the lack of sufficient water. Where there is a fair supply, the distribution is often at fault. More often than not there is an insufficiency of galvanised piping to lead it to the most important quarters, and always an insufficiency of hydrants. These are costly, but in a very short time they will save their cost in hose and labour many times over. These hydrants should never be more than a hundred feet apart, as a hose-pipe more than fifty or sixty feet in length is cumbersome to handle. Besides, the wear and tear on a long stretch of hose-pipe is very great. Therefore, the more hydrants there are, the least abuse there is to the piping. Fruit trees planted late this spring have suffered severely, even although the soil to the outward stretch of the roots was heavily mulched with manure and kept moist by watering. The strong sun heat and wind seemed to extract all the sap from the stems and branches. In many cases the trees will require drastic but intelligent pruning next winter if they are to pull through.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

The Early Orchard House.—Nearly all early Peaches and Nectarines will now be cleared of their fruits, and provision should be made for another year by potting and getting the trees thoroughly established without loss of time. The first consideration is the compost; as all stone fruits like, and must have, lime, the loam should be fairly dry, rather heavy, and of a calcareous nature. Correctives and stimulants may consist of bone-meal, lime-rubble, burnt earth and a little soot; if the loam is too light, dry, pounded marl may be substituted for the burnt earth. Pots should be clean, dry, and carefully crocked with potsherds, half-inch bones or oyster shells, and of sufficient size to admit the compost to be thoroughly rammed. Before potting, the roots and soil of the trees should be well soaked a day or two before they are turned out, as no after-watering will moisten a ball that is dry at the time of potting. Remove so much of the ball of soil as possible with a pointed stick, and cut back any straggling roots; when placed in the pot, the ball of roots should rest on some of the roughest of the compost, the top of the ball being about two-and-a-half inches below the level of the rim, to allow for an inch of compost above it and to leave room for liberal supplies of water. Return the trees to the house, which should be kept rather close and moist by frequent damping and dewing; if slightly shaded during very hot weather for a few days, the trees will soon take to the new compost and make fresh lateral growths, when ordinary treatment for a week or so may precede removal to the open air. Many older trees may be returned to pots of the same size, an operation which requires a little more care, hence the advisability of allowing the wood and buds to get a little further advanced before this work is performed. In many cases the old compost can be removed easily by immersing the roots in water for a short time. When the old compost has been reduced and the roots trimmed, repotting may be done, provided the compost is fairly dry. After potting, close, moist treatment as described above will restore the trees to active growth in about ten days.

Late Peach Houses.—The final thinning should have been finished. Keep the strong growths, and also shoots that will be removed after the fruits are gathered, pinched back; weak ones may be left full length. So soon as stoning is completed, a good top-dressing may be applied, together with liberal supplies of liquid manure nearly every day. Unless the fruits are wanted early, it is best to keep the side ventilators constantly open, and raise the air temperature by closing the top ventilators for a few hours on fine afternoons. Liberal thinning, good feeding and syringing are important factors, as half the number of good fruits will weigh as much as double the number which have exhausted the trees in the process of forming the stones.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Richardia africana.—Plants that have been rested should now be turned out of their receptacles and repotted. Shake all the old soil from the roots and grade the rhizomes into their respective sizes, selecting the largest for planting in eight- or ten-inch pots; those of a second size may be placed in five- or six-inch pots. If it is desired to increase the stock the best pieces that are left may be planted moderately closely together in boxes and grown on in a cool house. A suitable compost is composed chiefly of loam, with some decayed cow or horse manure and coarse grit added. R. africana, when growing freely, delights in plenty of moisture at the roots, being naturally semi-aquatic. After potting them, place the plants in a somewhat shady position, and where they can be protected from heavy rain. For the first few weeks little water will be needed at the roots, syringing, both morning and evening, being sufficient. In these gardens large numbers of Arums are planted out in borders; where this is practised the rhizomes should be planted in the kitchen garden and lifted and replanted inside when frost is expected.

Fuchsias.—These old favourites are not grown nearly so much now as in previous years. When at the R.H.S. Gardens at Wisley a few days ago, I was delighted to see two large houses devoted to Fuchsias, which were being grown for trial. It was pleasing to note varieties grown so well in days gone by when these subjects were grown extensively as specimens in large tubs. Cuttings should now be inserted for the purpose of raising young plants for flowering next year. The cuttings may either be inserted singly in small thumb pots, or several may be placed around the edge of a sixty-sized pot; where the latter method is practised, see that the young plants are potted singly before the roots become an entangled mass. When the cuttings have formed roots, stand the young plants on a shelf near the roof-glass in a cool house, and a few weeks later pot them on into three- or four-inch pots, after which they should be grown steadily on throughout the winter. Fuchsias that are still flowering will derive great benefit from frequent applications of liquid manure.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Early Potatos.—These will now be maturing, and should be lifted, during which process tubers of suitable size for seed purposes should be selected, and laid out in the sun, to "green," turning them every two or three days. These early Potatos may be stored in a dry shed until required, with a covering over them to prevent them turning green. The ground from which they have been lifted may be planted with autumn Cauliflowers or spring Broccoli.

Cabbages.—The sowing of Cabbages to yield produce for spring and early summer is an important matter, especially if a large and continual supply of vegetables has to be maintained. Seeds may be sown now and another sowing made about the twelfth of next month. Flower of Spring and Harbinger are two reliable varieties. Sow the seeds thinly in rows, so as to secure good sturdy seedlings for planting out.

Vacant Ground.—Ground upon which early Peas have been grown should be cleared and dug and manured, and planted with Broccoli for spring use. Should the ground be dry, give a good soaking of water before putting in the Broccoli, and place the plants in water for a couple of hours before planting them.

Parsley.—If Parsley is required for winter use, the early-sown plants should be cut well back to encourage the production of fresh growths, which will withstand the winter and provide good material for culinary purposes.

Spinach Beet.—So soon as the young plants are fit to handle, they may be planted in lines eighteen inches apart, allowing fifteen inches between the plants. This crop should prove valuable in the early spring, when green vegetables are scarce. Hoe between the rows frequently throughout the growing season.

Winter Brassicas.—The beds of Savoys, Cabbages, Kales and Broccoli should be examined and any gaps in the rows made good amined any vacant ground may be planted at once with these subjects.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Bearded Irises.—The enthusiasm which many eminent hybridists have devoted to these charming plants has at last brought them into a prominent place in the garden. No garden is complete during May and June without a collection of these easily grown plants. The popularity of the Iris is due partly to the comparative ease with which it may be grown, as it thrives, more or less, in any good garden soil, provided the position is open and sunny, and because it is an ideal plant for cultivation in towns, where it seems to be immune from the diseases which attack it under what one would consider more congenial conditions. Planting may be carried out from the end of July to early spring; perhaps from early August to the end of October will be found as good a period as any. Soil and situation are important factors; the former should be deeply trenched and generously enriched, applying well-decayed manure or decomposed vegetable matter as trenching proceeds, if the land is poor; avoid using fresh manure, which will cause sappy growth; such is conducive to rhizome-rot. Poor soils will be benefited by an application of superphosphate, and bone-meal may be used with advantage. Although bearded Irises are often planted in shady situations, they are really sun-loving plants, and delight in an open, sunny position where their rhizomes become baked in the sunshine, after flowering. Stagnant moisture is fatal to them. If the soil is deficient in lime, this should be added when the ground is being prepared. Planting should be done very shallowly, just placing the rhizomes on, or immediately below, the surface, and making them quite firm until the new roots get a hold of the soil. It is usually advisable to transplant these Irises every three or five years, but the grower must be guided in this in his own observations. At Wisley there are over a thousand varieties in the bearded Iris collection, and with the early-flowering pumila section, and then the intermediates, followed by the June-flowering varieties, they give a wonderfully long season of bloom at small expense in the matter of labour. If rhizome-rot appears, remove the diseased portion so soon as it is noticed and, if possible, transplant the Irises to another portion of the garden. A dressing of superphosphate will greatly help the plants to recover from, or prevent, this troublesome disease. The cost of many of the modern varieties is naturally high, as the increase of some is slow, but from the point of view of garden decoration, there is a wide choice in the various sections of the older kinds which contain ideal plants for ordinary garden purposes. Intending planters will find a good guide in the varieties that have done best in the trials at Wisley which, with descriptions, will be found in the *Journal* of the R.H.S. for January, 1928. These have all been grown under ordinary garden cultivation, and no variety is given any special treatment.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemont, Monkton, Ayrshire.

Vegetables.—Except in the most favoured localities, Prickly Spinach and winter Onions should now be sown. In specially favoured districts this work may be deferred for a week or so. A south border should be chosen where possible, the ground from which early Peas, Cauliflowers or Potatos have been cleared being quite suitable if lightly forked over and well trodden and levelled. Too rich a soil is not desirable, as the resultant growth will be soft and not likely to survive the winter. The seeds, in both instances, should be sown rather thinly, so that little if any thinning will be necessary. Rows one foot apart are most suitable, as this distance allows ample room for the development of the plants and also permits of frequent hoeing so long as the ground is workable. A second sowing of winter Cabbage should be made at the same time, in case the first sowing should prove too early, as it may should the weather be particularly fine. If not, the second sowing will winter in the seed-bed and be available for planting in spring.

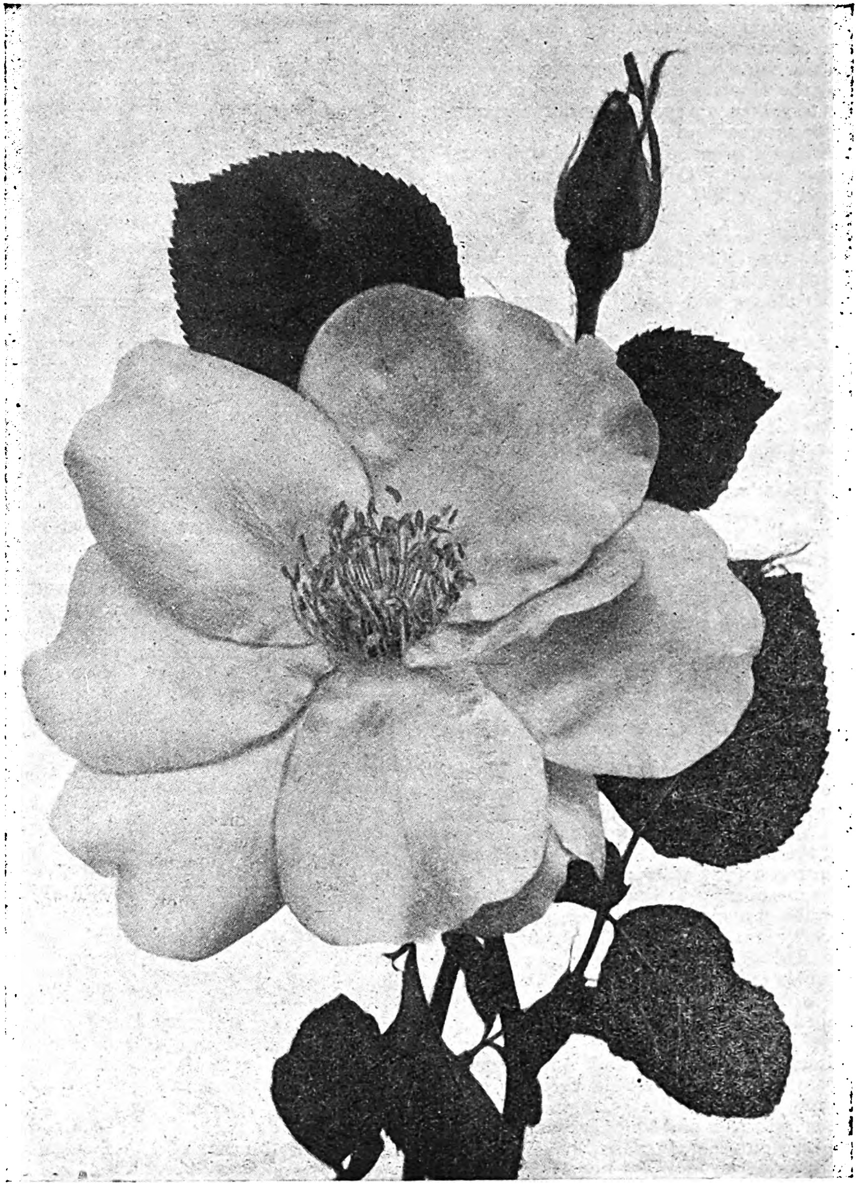

FIG. 38.—ROSE SENORITA DE ALVAREZ.
N.R.S. Certificate of Merit, July 23. Flowers large, single, satiny-pink. Shown by Messrs. B. R. Cant and Sons. (see p. 77.)

Malmaison Carnations.—These, having finished flowering, should be layered at once with a view to obtaining fresh stock. Only healthy, robust growths should be layered, and in no case should they be made long. A cold frame is the best place for rooting them, the soil being raised well up to the glass. Spread a layer of leaf-mould and sharp sand in equal parts over the surface. Turn each plant out of the pot and plunge the ball of roots on its side, spreading out the selected shoots all around. Remove all leaves up to the point selected, and make a good tongue by cutting half through the shoot; peg this securely into place so that movement is impossible. The growths should be almost upright when fixed, and as they should not be left long after roots have formed, they may be pegged fairly closely together. Water them at once, afford shade from sunshine, and syringe them frequently until rooted, which should be in about three weeks. Plants selected for growing on should be potted at once in pots at least two inches larger than those now occupied. Three parts good fibrous loam, one part old cow manure, and rough sand, lime-rubble and broken bricks or drain-tiles equal to at least one part, with a dusting of Carnation manure and bone-meal, should prove a suitable compost. Good drainage is essential. The plants should be well watered previously to being repotted, and the potting soil should be in a dry, rather than a wet, condition. Pot the plants firmly, using a wooden rammer for the larger specimens. Place the plants in the coolest house available, shade them from sunshine, spray them overhead on hot days, and give water at the roots only when they show signs of flagging. They should be placed on a good bed of ashes, and this should be kept moist. Should thrips or red spider appear the plants should be dipped or sprayed.

TREES AND SHRUBS.

VACCINIUM VITIS-IDAEA.

THIS is a charming little shrub for the rock garden and one that does not appear to have had its great merits duly recognised. It may be cheap and a native, but its evergreen, Box-like leaves which cover the wiry, twiggy growths some six inches long, are pleasant at all seasons, and it can put up no small claim to be a flowering and fruiting subject of distinction. The blossoms appear during May and early June in clusters of a dozen or so, each having a four-lobed, bell-shaped corolla which is waxen-white, with rosy markings and a length of a quarter-of-an-inch. These are quickly followed by the berries, which are about the size of those of Holly, and much the same colour, but, as they ripen in succession, the clusters give a variety of tints from green to yellow, orange and scarlet, throughout the later summer and autumn.

The Cowberry is certainly "the handsomest of our native species" (W. J. Bean), and I have spent a good many half-crowns on other Vacciniums which are not nearly so good. It is, of course, perfectly hardy (I came upon it the other day close to the 3,000 feet line in Snowdonia) and enjoys a fairly cool, peaty or vegetable mould with stones and grit. Full exposure is desirable.

Although apt to run and thus form a wide mat, I have not found the plant troublesome in that respect. Its right place is doubtless the Heath garden, occupying wide crevices between boulders, but it is useful with almost any other Ericaceous shrubs. One wonders why Linnaeus gave this shrub the specific name of Vitis-idaea, the "Vine of Idaea"—presumably a mountain of Asia Minor—when it is so essentially a northern species and must have been plentiful in his own land. *A. T. J.*

CAMELLIA JAPONICA.

ALTHOUGH not generally recognised as such, Camellia japonica and its many beautiful varieties, ranging in colour from deepest red to purest white, and in form from five-petalled singles to perfect doubles, is one of the very best of hardy evergreen shrubs. It is not adapted to exposed, wind-swept positions, but if sheltered from the north and east winds, it makes a shrub of singular beauty, lovely both by reason of its lustrous, dark green foliage and its delicate, exotic-looking blooms. Of its hardiness, there is no doubt, for Mr. W. J. Bean, of Kew, records that it has withstood 31° of frost without suffering in the least.

When fully-grown it makes a small tree thirty to forty feet in height, but plants smaller than this and of more bush-like proportions are admirable for the small garden. A sheltered situation is advisable, so that the flowers, which appear from April to June, may have an opportunity of developing their full beauty without harm from late frosts. As a general rule, the single and semi-double varieties open their flowers better in the open than do the double-flowered sorts, and for this reason should be selected for out-of-door planting.

It is advisable to purchase a plant of fair size for planting out, or alternatively to grow on a small plant in a greenhouse for a couple of years or so, for very small plants grow slowly at first if planted out. A peaty soil or one containing an appreciable proportion of leaf-mould is desirable. *T. H. Everett.*

HOHERIA OR PLAGIANTHUS.

PLAGIANTHUS Lyallii and the variety glabrata are two of the comparatively few New Zealand shrubs, or small trees, which are reasonably hardy in most British gardens. It may appear strange to some interested readers to know that both shrubs passed unharmed through the long spell of frosts, when, on several consecutive nights, from 20° to 25° of frost were registered. The explanation would appear to be that a see-saw temperature of 30° or 40° in forty-eight or seventy-two hours, with perhaps some rain, does far more harm to the branches of shrubs on the borderland of hardiness than a continuous severe spell of dry, cold weather.

These beautiful deciduous shrubs or small trees, nine to ten feet or more in height, produce their flowers several together from the axils of the leaves on the new shoots of the year, the blooms being of a papery whiteness, one-and-a-quarter to one-and-a-half inch across. These two Plagianthuses are among the most beautiful of shrubs for the pleasure grounds and shrubbery borders. In exposed gardens in the north, where Plagianthus Lyallii and var. glabrata may be of doubtful hardiness, they will be found excellent subjects for a sheltered south or west wall.

The two are readily distinguished by the leaves, even with the eyes shut, the downy character of the leaves being so marked in the type, P. Lyallii, as to give the shrub a greyish appearance. The type is also rather more upright in habit of growth, and the flowers more translucent than in the variety glabrata. Seeds, layers and cuttings are all available as methods of increase.

The most satisfactory soils are those on the light side, and well-drained; the least success may be expected on heavy, wet ground.

A third generic name for these shrubs, and the one used in the *Botanical Magazine*, t. 5,935, is Gaya Lyallii. *A. O.*

APPLES AND PEARS AS ORNAMENTAL TREES.

A SHORT time ago it was my pleasant privilege to pay a visit to the garden of the Managing Editor of *The Gardeners' Chronicle*, and while I admired his Liliums, and incidentally was amused to see him with a pointed stick removing the top-dressing material so that the growths of his favourites could meet the sunlight, I confess to even greater admiration for a venerable and tall Catillac Pear tree growing in the middle of the garden, as a permanent memorial—so I thought—of the time before London had spread its tentacles of bricks and mortar so far out as Brentford and the market gardens of the district supplied the metropolis with a big quota of its fruits and vegetables.

It is a fine old tree, that Catillac Pear, worthy of a place as an ornament in any garden and the sight of it set me thinking. I decided to invite Mr. Curtis to come to the West Country where the cider Apples and Perry Pear trees grow, and form his own opinion of them as ornamental trees, quite apart from their utility value. Well, he came and saw, and this article is the outcome of his suggestion that something about these trees might be of interest to the readers of *The Gardeners' Chronicle*.

Let me take the perry Pears first, which for some unexplained reason are chiefly confined to Gloucester, Hereford and Worcester, for Somerset and Devon, although famous for their cider, have never grown perry Pears. In many of the orchards in the counties named, there are venerable and ornamental specimens of trees, capable in a good season of bearing a ton and more of fruit, and their origin belongs to a period in history when perry and cider were the staple, if not the only, beverage consumed in the west country.

A good example of these ancient fruits is the Barland Pear, which is described in Hogg's *Fruit Manual*—still a classic, by the way, in fruit nomenclature—that was grown in Hereford prior to the publication of Evelyn's *Pomona* in 1674, and it is safe to state that some of the trees then referred to are still alive and bearing. The original tree is stated to have grown in a field called Barelands, in the parish of Bosbury, hence the name. One would like to have the history of many of the old Barland trees that still remain, and know something of the changes they have witnessed since they were first planted.

Then there is the Oldfield, the fruit from which is considered by many experts to make the best of perry, and the Malvern Hill, which, as an accident of nature, made its appearance in the vicinity of the Worcestershire hills after which it was named. Away back in the years that are long gone, there was raised, or rather, nature raised it, in the Severn-side village of Norton, near to Gloucester, a perry Pear that is known as the Norton Bull, perhaps because the farmer on whose holding it originated bore that name. Be that as it may, the Bull Pear is found in many of the orchards in the locality, and quite apart from its bearing propensities as a specimen tree, it is extremely ornamental.

The Taynton Squash originated in another Gloucestershire village of that name, and at Blakeney, a village on the outskirts of the Forest of Dean, nature produced another Pear which the natives called the Blakeney Red, on account of its bright colour on the side of the fruit exposed to the sun. Blakeney Red has a long history; in prolific seasons in the past tons of the Pears have rotted on the ground because no one would pick them up, but one year, in the war, Blakeney Red had fame thrust upon it. There was a big crop, which by a curious coincidence was not controlled in the matter of price. Tons of the Pears were sold at a shilling a pound wholesale, and farmers still talk about paying the rents of their holdings out of the crops of three or four trees of Blakeney Red Pears.

Nowhere outside the western counties are these perry Pear trees to be found, and so ornamental are they as specimens that if they could be transferred to public parks and gardens they would be much admired, if only as a contrast to the inevitable Limes, Planes, Elms, Chestnuts and Sycamores which are so common everywhere.

Regarding cider Apples as ornamental trees, let me instance Strawberry Norman, which is a bitter-sweet Apple valued by the cider-maker and, as its name indicates, originated in Normandy, from where perchance it was brought by some monk or holy friar, and planted in the orchard of one of the religious houses that flourished in the west country prior to the reformation. Strawberry Norman has a very distinct habit, inasmuch that its branches, which are spurred right back to the stem, grow out from the latter almost at a right angle, and the spread of branches on trees I know that have not been planted twenty years is more than thirty-six feet. What a picture an avenue of Strawberry Norman Apples would make, and for providing shade on a lawn I cannot imagine a more suitable specimen tree.

Then there is Eggleton Styre, another Apple of quite ornamental and distinct habit. In this case the branches are slightly pendant and when right away from the stem they take a turn upwards, just as if the leading shoots were doing this to meet the sun. In an orchard, this distinct habit is noticeable, but it would be even more so if a tree was standing alone as an isolated specimen.

In Sweet Alford, a native of the broad-acred county of Devon, from which a lot of the Devonshire sweet cider is made, there is the most perfect specimen of a standard orchard Apple I know, and its growth is as graceful as it is rapid. All that Sweet Alford asks for is to be planted and left alone. It will shape itself, it needs little or no pruning, and specimens I have planted myself, not twenty years ago, now resemble fair-sized forest trees. When in bloom, the tree is beautiful, and it is equally attractive when the golden-yellow Apples on the branches are approaching ripeness.

It is not my intention here, however, to enlarge on the beauty of cider Apple trees before the fruit begins to fall, but this point is worthy of mention, some of the varieties being striped yellow, brilliantly red or as deep a red as it is possible to get. And, perhaps, without an exception, nature produced all the varieties; they are accidents of her own, and the only object of perpetuating them was to feed the cider mill, but if any public authority is on the look-out for a change in the way of ornamental trees to beautify a park or garden, let me recommend them to consider the claims of west country cider Apples and perry Pears. *A Man from Gloucester.*

ALPINE GARDEN.

AQUILEGIA PYRENAICA.

Farrer devoted nearly two pages of his *English Rock Garden* to this diminutive Columbine, but most of the matter consists of a heroic struggle with the various forms of this species, a "debatable land strewn with the corpses of botanists dead in mutual war" over the plant's differences—and theirs. A. pyrenaica, however, does something towards simplifying matters by keeping itself to itself in the mountains after which it is named—a rare concession in a Columbine. At any rate, the learned in such things tell me that A. pyrenaica is strictly Pyrenean in range, and that all other claimants to its name and rank are scattered elsewhere over southern Europe. That fact, together with the knowledge that my plants came direct from the Pyrenees, sustains my belief that they are of the genuine article.

This neat little plant has been, not unworthily, described as A. alpina in miniature. But it is, in addition to being so much smaller, considerably more refined in all its parts. The few loose sprays of small, pale-green leaves are extremely light and airy in effect, and the almost leafless flowering stalk, which hardly attains one foot, bears flowers of no more than an inch across. These are a deep, royal blue, which is accentuated by the central tassel of golden stamens.

A. pyrenaica is hardy and by no means difficult in a moraine mixture or any gritty soil, provided it is rather on the cool side, with shade from the mid-day sun. It is stated to enjoy lime, but does not insist upon it. I have not tried this species from seeds, but there is reason for believing that it will come very fairly true by that means.

INULA ENSIFOLIA.

So many of the taller Inulas are either troublesome underground runners (it took me ten minutes to put one in and ten years to get it out), or mop-headed, sprawling growers, that practically all of them have had their places taken by better things.

The subject of this note is one of the others, a charming, well-behaved plant whose ranks of slender stems are hidden beneath a fine blaze of warm gold from early July onwards. I. ensifolia does not exceed twelve inches with me. The bronzy stems are wiry and invariably hold themselves erect, and the crisp leaves are narrowed down so as to be in nice proportion to the size of the flowers, which are about one-and-a-half inch across.

The plant increases by off-sets, but it does so slowly and always remains in a self-contained clump. I. ensifolia, moreover, will grow anywhere, and I find it a most useful plant for poor soils and sun-beaten places. At the same time, to see the species at its best it should have a well-drained, stony, but good loam that does not get too parched, and full sun. *J.*

CAMPANULA RAINERI.

For the limestone scree I can call to mind no greater treasure, no gem of beauty more luxuriant, than the true Campanula Raineri. It is not always true as grown in gardens; too often C. pseudo-Raineri is supplied in its place by those conscienceless nurserymen—oh, those nurserymen ! ! !—and although a lovely plant, it loses its appeal after having been carefully planted for the true C. Raineri in the centre of the choicest scree.

C. Raineri is that rarest of rarities, a treasure without a fault; it is easy of culture, easy of propagation and appears with unfailing regularity each spring, no matter what the winter conditions may have been—such, at least, has been my fortunate experience. Its greatest, and almost its only, enemy is the iniquitous slug, and as we are almost free from the pests here, I do not write of their depredations with such vehemence as would be called from the pen of one who had recently mourned the close-eaten remains of some choice Campanula. I certainly take the precaution of placing zinc rings around patches of C. Zoysii and C. Morettiana (yes, patches of C. Morettiana), and other succulent delights, for who knows when the word may go forth to some slug-haunted garden where food grows scarce? and we have Mr. Elliott's word for it that a slug will crawl ten miles for a banquet! But this is all by the way, it is so easy to be discursive, both in the garden and when writing about it.

FIG. 39. MONSERRATE: THE OLD INDIAN GATEWAY.

My best plant of C. Raineri this year is situated on a fully exposed, north-facing scree, the downy, grey, sharply-pointed little leaves forming a running tussock some six inches across, and for the past three weeks this has been completely hidden under nearly forty of the huge, china-blue chalices, each marvellously borne on a frail, inch-high stem. Every flower was almost two inches across, and the effect of the mass of these, all open together, may be well imagined.

FIG. 40.—MONSERRATE: THE ENTRANCE TO THE PALACIO.
(see p. 90).

Happily, C. Raineri may be propagated from runners cut off underground when growth commences in the spring, potted in a sandy mixture, and kept close for a week or two.

C. pseudo-Raineri is by no means to be despised, except as a substitute for true C. Raineri; it is larger and, to my mind, gains a certain amount of blatant self-complacency with its size, but it is well worth planting for effect in large groups on the rock garden, although far too large for the scree. *Will Ingwersen, The Birch, Sharpthorne, Sussex.*

INDOOR PLANTS.

ARISTOLOCHIA GIGAS.

Aristolochia gigas (syn. A. grandiflora) is the largest-flowered species of a very big genus, which includes members from all parts of the world. The blooms on the plant here at Cambridge, which has been flowering lately, are nine inches across and ten inches long, and possess a tail quite eighteen inches in length. They open in the early morning and remain fully expanded for about twenty-four hours, at the end of which time the edges begin to curl inwards, and in a few hours the flower has completely faded.

The colour is a brownish-purple and mottled, shading deeper towards the cavity in the centre, which is dark chocolate.

The only drawback to this handsome bloom is its distinctly unpleasant odour, which attracts numerous blow-flies. They pass down the throat and are trapped by the hairs at the entrance, which allow them to enter and effectively prevent their egress; this is the plant's method of ensuring fertilisation. The leaves, four or five inches in diameter, are cordate and slightly downy.

The compost in which this plant thrives best is one similar to that employed for Cucumbers. The specimen here is planted in the tropical Orchid house and trained up under the roof. Plenty of weak liquid manure, occasionally ringing the changes with soot-water, should be given so soon as the plant shows flower buds.

A. gigas was introduced from Guatemala in the year 1841. *F. H. Wright.*

UTRICULARIAS.

For practical purposes, the Bladderworts may be divided into two sections, *i.e.*, aquatic, and epiphytal, or terrestrial. Several aquatic species may be found floating in still water in Britain and Ireland during the summer months, all with yellow flowers rising above the surface, while the submerged leaves are characterised by fine, subulate divisions, some of them bearing small bladders, or pitchers, thus accounting for the common name. These native species form winter buds at the ends of the leaves, and hibernate at the bottom of the pond, rising again when growth begins in spring.

The epiphytic species usually bear bigger and more striking flowers and have larger, entire leaves. Six or more species of this section have been known in cultivation from time to time, but very few have been established permanently. Three of them are in cultivation here, viz., U. Endresii, from Costa Rica; U. longifolia, from Brazil, and U. montana, from the West Indies. They thrive in Orchid baskets in a mixture of fibrous peat and Sphagnum-moss. Of these, the most successful is U. montana, a beautiful species producing flowers one-and-a-half inch across, pure white, with a yellow disk on the lip, the spur of the corolla being stout and incurved. The leaves will reach to a length of six inches or more, and are broadly lanceolate, tapering to a slender petiole; green, ovoid tubers are produced on the roots. U. Endresii is a less robust species, which has also been known as U. montana var. rosea, but the corolla is pale blue or lilac, although the sepals may sometimes be reddish. The plant is smaller in all its parts than U. montana, but thrives under conditions afforded this species, in peat and Sphagnum-moss, in a warm Orchid house. U. longifolia, from Brazil, bears erect, lanceolate leaves, and its flowers are described as violet-purple in colour. Plants in cultivation here for some years have increased, in baskets of peat and Sphagnum-moss, but have not yet flowered.

Two other interesting species are U. coerulea and U. prehensilis, both from tropical Africa. They flourish in large pots of saturated mud, just covered with water. The whole surface of the mud becomes covered by the dense mat of linear, entire leaves of a bright green colour. From among them arise slender, thread-like stems which twine around twigs, or any similar support within reach, and bear, in the case of the former, pale bluish-white flowers, and in the latter, bright yellow flowers; the flowers, however, are small, although numerous.

The Bladderworts belong to the Natural Order Lentibulariaceae, which includes also the Butterworts (Pinguicula). The biology of the bladders produced by the aquatic species has received considerable attention from botanists, but, apparently, less attention has been given to the significance of the tubers on the roots of the epiphytal and terrestrial species. *J. W. Besant, Glasnevin.*

BULB GARDEN.

HYBRID LILIES.

In your review of Miss Preston's work on Lilies (p. 29, July 13), you suggested that although many hybrid Lilies have been raised from time to time, few, if any, are improvements on the wild plant.

Now, it was my fortune to read these remarks sitting on the lawn of Sutton Court in company with Mr. R. O. Backhouse, the raiser of so many wonderful Daffodils. The purpose of my visit was to enjoy a hurried look at his many fine seedling Lilies—and we at once remarked that if the writer could see what we saw, he would undoubtedly come to a different decision—tall, stately groups of Lilies, five feet to six feet high, in perfect health, carrying great stems of flowers in all shades of colour. Close by was L. Hansonii and seedling forms of L. Martagon and its variety dalmaticum, from which they had originated. In vigour, stature, size of flowers and diversity of colour, they far exceed the original types.

It is well-known that the late Mrs. R. O. Backhouse originally crossed L. Hansonii with various types of L. Martagon, intercrossing the results, so that now, in the second and third generation, many new types have appeared, some after the L. M. var. dalmaticum colouring, fully six feet high, the slender inflorescence typical of L. M. var. dalmaticum taking on a bolder habit with a more panicled stem (the influence of L. Hansonii), while in others there are all shades of yellow from deep orange to pale citron and white, and of L. Hansonii substance. In the Mrs. R. O. Backhouse type they lean more to L. Hansonii in shape of spike—the variation in spotting being most marked, from a few light spots to the other extreme. Some of the L. Martagon types are so freely spotted as to be practically covered. The pollen also varies from pale yellow to crimson. Again, the spotting occasionally shows on the outer petals, which are generally of a different shade.

Imagine the beauty of a bed of one hundred spikes, four feet to six feet high, no two the same! The finest types are being selected and grown, but Lily propagation is none too fast in this country. Our climate is not that of the west Pacific coast. Still, I look forward to the time when these Lilies will be available in quantity. Their constitution is good. They are not miffy in any way, and they come of a class that is, in the main, suited for ordinary garden culture.

Some years ago, I introduced the public to the Davison race of Montbretias, the forerunners of the Earlham type, and later on in life the Bliss Irises—Dominion, Bruno, etc.—improvements on existing types. The undoubted popularity with which these have been received gives me confidence when I venture to predict that, as time goes on, these Backhouse Lilies will become firmly established in our gardens, and that garden lovers will be grateful for their introduction, and will give them a warm welcome on account of their increased vigour and diversity of colour.

Sitting in the shade at Sutton Court, with Lilies in flower all around, and having just read the comments referred to, I was prompted to send you these notes. *Robt. W. Wallace, Tunbridge Wells.*

[We heartily endorse Mr. Wallace's remarks regarding the beauty and markings of these hybrid Lilies, as Mr. R. O. Backhouse very kindly sent us a box of spikes, together with individual blooms of many varieties. EDS.]

FLOWER GARDEN.

ANNUAL COREOPSES.

MOST of the hardy annuals which are suitable for autumn sowing are of procumbent growth, and are mainly early spring-flowering, but the annual Coreopses are of erect growth, and are not in full beauty until the middle of the summer. They are among the brightest of garden flowers, and are exceedingly rich if cultivated in masses, when they are, especially for distant effect, very striking. At the back of herbaceous or mixed borders, or for relieving the sombre aspect of the shrub border, few, if any, annual plants can compare with these. Neither are they transient, for they continue in beauty almost throughout the summer.

They are of the easiest culture, and are not affected by extremes of wet or dry weather to the same extent as are most flowering plants; and, further, they will flourish not only in the country, but will contribute their brightness to town gardens. Their colours—yellow, red, and crimson, separate or in combination—are very brilliant, while in foliage and habit they are, if not elegant, certainly agreeable.

Seeds of these annual Coreopses are generally sown in spring, but when so treated the plants are late in coming into bloom. To have them early, continuous and fine, they should be raised from seeds sown in autumn; but sowing should not be deferred until September, which is the correct time for Nemophilas, but not for Coreopses. The latter are of slow growth in the early stages and, to afford them time to attain to a safe size to pass through the winter, seeds should be sown not later than the third week in August; if the seedlings are thinned out early they should withstand the winter's frosts.

Those who covet a great display for a little outlay of money and trouble, cannot do better than sow seeds thinly in drills early in the present month. The seeds should be only very slightly covered. The varieties, which are all showy, may be selected from any reliable seedsman's catalogue, according to the heights and colours desired.

I might state that a new variety being grown here, called Mayfield Giant, is very desirable, being rich, deep, golden-yellow in colour. *James A. Paice, Copseham, Esher.*

GARBENING BASKETRY.

WHAT sort of basket is a garden basket? The query is one which many gardeners would not feel able to answer offhand. The majority would probably name the Sussex trug, which is not strictly a basket at all, and others would mention some particular design of basket, round, oval or oblong, for which they had a preference, or which they had been given to understand was the correct type for garden use. Others, again, would express the opinion that there was no such thing as a garden basket as such, but that one just used an ordinary basket which happened to be suited to some particular purpose in the garden.

And these last would be nearest to the truth; for, if we leave out the trug (or truck, as it is sometimes called), which is made of thin Willow-wood supported on an Ash frame, there really is no other basket which can be put down as a garden basket, and nothing but a garden basket. One has only to examine the illustrations of garden baskets in a catalogue, or inspect the baskets themselves in a shop, to see that they do not differ materially from baskets in general use, although some may have just that difference in proportions which indicates that they have been specially made to the order of a firm of garden requisite suppliers. The gardener can, therefore, exercise his own choice and judgment in the selection of a basket or baskets for gardening purposes; and can obtain what he requires from any shop which stocks a variety of baskets.

The most handy basket for weeding, thinning Onions, Carrots, etc., is no doubt the trug, and this can be used for other purposes also, such as gathering fruits and vegetables. Being made of solid boards, it permits nothing to sift through, and can easily be kept clean; but these advantages are possessed by an ordinary bucket, which many gardeners use instead of the trug. Where the wicker basket scores is in comparative lightness of weight, so that where large quantities of fruits or vegetables have to be carried, a wicker basket is to be preferred to either trug or pail. In large gardens a big, oval basket, with handle across, is useful for collecting and carrying vegetables into the house. This is from twenty to twenty-four inches long at the top by about a foot wide, and can with advantage be narrower in the middle where the handle is than at the ends, for convenience in carrying. It can be either of peeled or unpeeled wicker, the former being the stronger and more lasting, but not so easy to keep clean. Another useful basket for the same purpose is the round peck "cob," used largely in East Anglia, and there is, also, the oval greengrocers' basket, holding half-a-bushel, which is common in the south of England.

An Apple-picking basket may conveniently be round, with a handle across, like the "cob," but somewhat larger. A metal hook for hanging it to the tree branches is a useful accessory. The ordinary shopping basket is as good as anything for many kinds of fruits and flowers also; in the case of soft fruits, the basket should be lined with tissue paper or large leaves. A popular basket with women gardeners is the "cut flower" basket, either in buff or a mixture of brown (unpeeled) and white (peeled) Willow. Of the various shapes, perhaps the most popular is that which has a curved bottom, something like a punt. A very useful and handy device is a combination stick and basket, the stick having a pointed ferrule so that it can be stuck into the ground, supporting the basket at a convenient height, and leaving both hands free. For sending cut flowers by post, light oblong wicker baskets with lids are much in favour. Postal regulations regarding size must be borne in mind; the length must not exceed three feet six inches, and the length added to the girth must not total more than six feet. These baskets can be made to order by any basket-maker, and the following dimensions for three sizes will serve as a guide: Twelve inches by eight inches by four inches deep; eighteen inches by ten inches by five inches deep; twenty-four inches by twelve inches by six inches deep. These are inside measurements, *i.e.*, the measurements which basket-makers normally work to. For sending fruit and vegetables by rail, "Xmas" hampers of unpeeled wicker are suitable, and so are Watercress "flats"; for large quantities a stout hamper of white wicker makes an ideal container.

Oblong baskets with sloping sides and handle across, fitted with gardening tools, can be obtained, but it is doubtful whether the practical gardener finds much advantage in this combination. Of other types of basket used by gardeners, mention may be made of the "whisket," "scuttle," or "skull" type, used in the midlands and north of England, and in Scotland, which is a very serviceable basket made of split cane woven on stout Hazel ribs, and having a hand-hole at either end; and the round bushel and half-bushel basket with handle on each side of the top border. One of the latest novelties is the wicker wheel-barrow, much in favour with women gardeners owing to its lightness. It is particularly useful for collecting leaves, and does not leave heavy wheel-marks on lawns as the heavier wooden barrow is liable to do. *A. G. Knock, Editor of "Basket and Cane Trades Journal."*

GARDEN NOTES FROM SOUTH-WEST SCOTLAND.

It appears strange that Rhododendron eximium should be grown in so few places in this country, seeing that it was discovered in Bhutan by Booth more than seventy years ago, is perfectly hardy if protected from strong wind, and is an extremely ornamental species. Being nearly akin to the Sikkimense R. Falconeri, the question whether it should be classed as a geographical variety of that species was discussed by the late Sir Isaac Bayley Balfour and decided in the negative. The features upon which he based his decision are the persistently bearded petioles, the rose-coloured flowers, the densely glandular ovary and the character of the indumentum on the under-sides of the leaves. For the ordinary observer, what serves chiefly to distinguish between the two species is the period of starting into growth and the remarkable appearance of the young leaves of R. eximium. While both species flower in late April, R. Falconeri beginning its young growth about that time, the growth buds of R. eximium (here at least) show no sign of moving until the end of June. Once started, however, they proceed to make a most attractive display, the young leaves being densely clothed with orange-tawny fur on both surfaces, the upper surface retaining the covering until mid-winter. Mr. Millais describe this species as being of very slow growth in Sussex; but on our largest plant here, seven feet high, the annual shoots average fully six inches.

The genus Inula contains several showy species but none, so far as known to me, equal to I. Royleana from the Himalayas. I. grandiflora, I. Hookeri, etc., are disposed to flop and require staking; whereas I. Royleana holds its flaming disks boldly aloft, asking for no support or anything better than ordinary garden soil. There is a finely coloured plate of this flower, from a drawing by H. G. Moon, in Mr. Robinson's *Flora and Sylva*, Vol. I.

Let me endorse Mr. A. T. Johnson's encomium of the Madeira Broom—Genista virgata (p. 48). A large bush here, twelve feet high and twice as much from flank to flank, presented such a sorry sight after the blizzard in February as to make one think it had succumbed, but in mid-July it put forth its invariable cloud of golden blossom, in agreeable contrast with the silvery foliage of Cedrus atlantica var. glauca beside it.

Never in my recollection has any herb sprung so suddenly into favour and spread into so many gardens as Meconopsis betonicifolia has done. Only three years ago I was introduced to it for the first time in the beautiful grounds at Bodnant; this year one meets with it in every collection worthy of the name. Moreover, it has come to stay; and, being a robust perennial, need fear no rival in the variety Baileyi, which, being monocarpic, makes but once a display of its matchless azure.

The numerous species of Daisy Bush cover a long flowering season. The clouds of blossom on Olearia macrodonta and O. ilicifolia become tarnished in July, to be followed by a similar display on O. nummularifolia and O. avicenniaefolia, to be succeeded in August by the latest of the series, O. Haastii.

Voles have multiplied this year to a serious extent, and have wrought much mischief among Lilies—underground among the bulbs and gnawing the stems and foliage, especially of Lilium candidum and L. testaceum. Accounts reach me from Dumfriesshire of much damage done by these pestilent rodents in young plantations. A correspondent asks me whether the shrew mouse does some of this evil work. It cannot be too generally known that the shrew is incapable of injuring trees or plants. It is not a mouse, although it resembles one, but belongs to a totally distinct Order. Rats, mice and voles belong to the Rodentia, whereas the shrew belongs—like the mole and the hedgehog—to the Order of Insectivora, and subsisting entirely on an animal diet, devouring worms and the larvae of insects, is beneficial to both gardening and forestry. Give a dog a bad name!—the shrew has suffered unjustly from being popularly known as the shrew mouse.

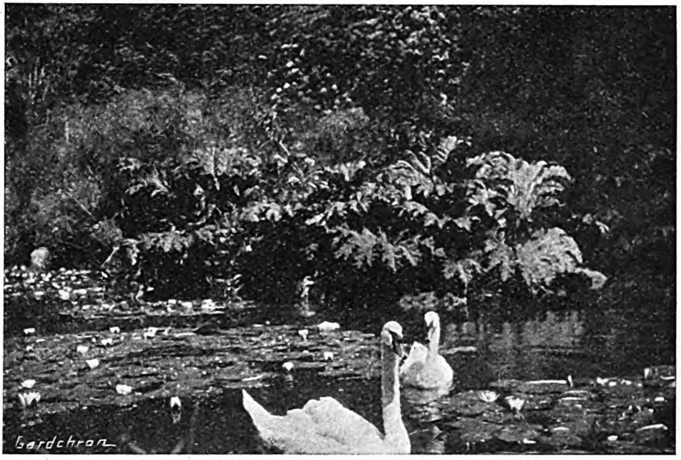

FIG. 41.—MONSERRATE: THE SWAN LAKE.
(see p. 91).

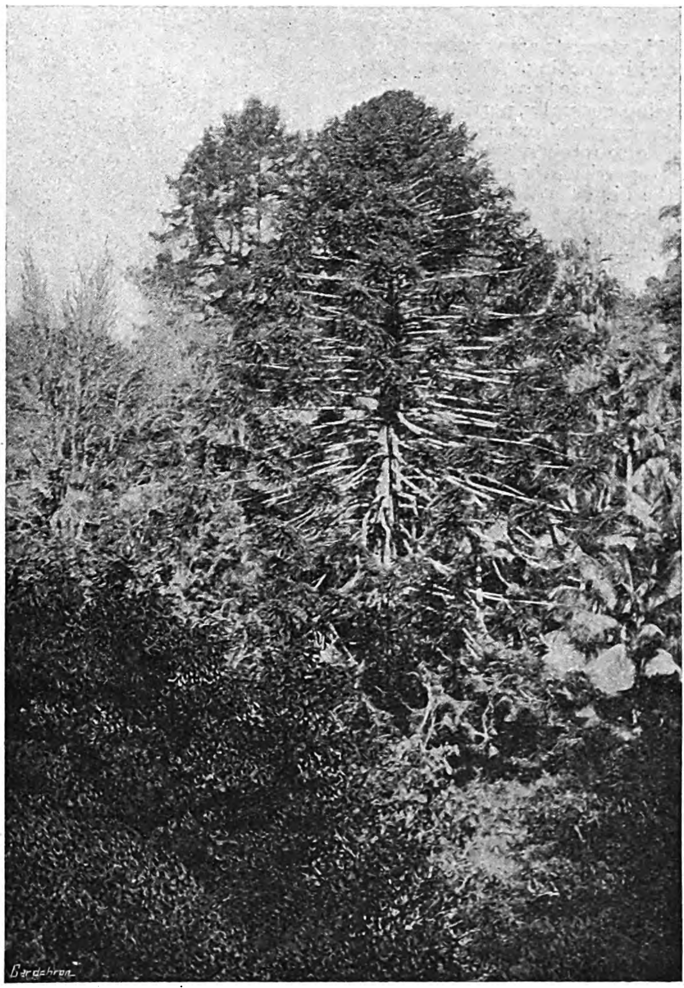

FIG. 42.—MONSERRATE: ARAUCARIA BIDWILLII.
(see p. 90).

Having in a former number availed myself of the hospitality of your columns to express gratitude to a generous lady who sent me bulbs of Fritillaria tristis, may I do so again after receiving some seedling Moraeas. It is the only way in which I can make acknowledgment of the gifts, for although the kind donor signs her letters, they do not bear her address! *Herbert Maxwell, Monreith.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar, 7818.*

MONSERRATE.

THE gardens of Monserrate are very beautiful, extensive and interesting. They are situated in the folds of the Serra of Cintra, on a very steep slope facing, generally, north-west, and are thus sheltered somewhat from the fierce heat of mid-day, and able to retain a large amount of humidity which is particularly suitable to the requirements of the big collection of Tree Ferns and many other plants that thrive luxuriantly in hot, moist conditions. In a deep ravine, the water dashes downwards in cascades from a high waterfall at the top to the ornamental lakes which lie far below at the foot of a large lawn that is crowned by the large and very decorative Palacio (Figs. 40 and 44).

The sides of the ravine are steep, with here and there a large rock standing out boldly and covered with Ferns. The great, glossy fronds of Woodwardia radicans hang over the rocky-edge, and are gently swayed by dashing, silvery spray from the rushing water beneath. Overhead tower the stately Tree Ferns—Cyathea, Alsophila, Dicksonia and others. Large groups of Pteris, Davallia, Asplenium, Blechnum, and many other Ferns fill the spaces between the towering trunks, completely covering the rich vegetable soil in which they revel; all are sheltered and shaded by large Cork Oaks and the beautiful Arbutus Unedo. Here, too, many species and varieties of Begonia thrive. Giant plants of B. arborescens, with long, pointed metallic-hued leaves, and thick, ribbed stems, bear large trusses of delicate white flowers in the early spring; while, on the rock-work beneath, B. manicata forms large, soft cushions of dark green leaves surmounted by dainty pink flower heads. B. Rex, in many fine varieties, grows well in any available nook, while tuberous Begonias flaunt themselves in a few borders.

Higher up, on the sunnier side of the ravine, huge Camellias thrive and flower in great profusion; and here and there among the Ferns rise large plants of Fuchsia corymbiflora, and F. arborescens, with bright pink panicles of flowers, which visitors often mistake for English Lilac. Here, too, are some grand examples of Luculia gratissima, whose large trusses of soft pink flowers fill the whole ravine with their delicate perfume in late autumn. In the crevices of the rocks is found the rare Ivy-leaved Fern (Asplenium Hemionitis) which grows quite freely among mosses and Lycopodium.

Along the sides of a path which crosses the ravine, whence a fine view of it can be obtained, are irregular rock borders in which, beside many Ferns, Primulas of various species and varieties, Cyclamens, Cypripediums and other old favourites, make a good show, shaded by enormous Plane trees (Platanus orientalis), of which one is a great curiosity, having a Cork Oak growing from the same root; the explanation is that the Oak was used originally as a stake to support the young Plane tree, and they grew together, the Plane gradually enfolding the Oak within its roots.

A little way along the path are the ruins of an old Chapel, within which are beds of rare Palms, Ferns and Begonias, with climbing Roses and Wistaria clambering over the bare old rafters of the open roof. The front of the Chapel is covered with Ivy and Ficus repens—and shaded on one side by a superb Catalpa speciosa, and on the other by a huge Ficus rubiginosa. A small pergola supports Tacsonia mollissima and Passiflora actinea, while two small pillars nearby are covered with Kennedya (Hardenbergia) Comptoniana, Honeysuckles and Thunbergia alata.

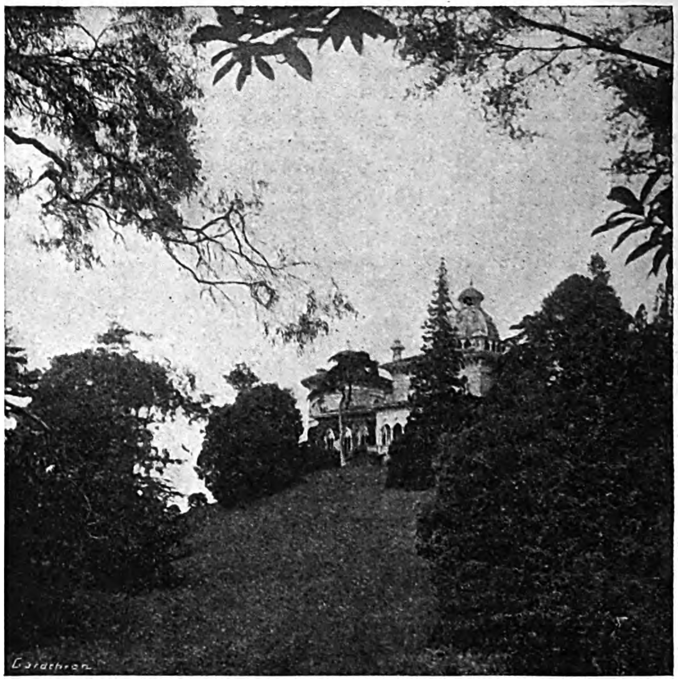

FIG. 43.—MONSERRATE: THE WIDE, SLOPING LAWN.

To the right of the Chapel terrace is a dark glen, sheltered on one side by a very big, old Cupressus lusitanica, with particularly fine drooping foliage, and, farther back, by large groups of Bambusa gigantea, and groups of Camellias. In the foreground are two fine specimens of Cyathea medullaris, large Alsophila Moorei, Dicksonia antarctica and D. squarrosa, and a good plant of Cyathea dealbata, associated with Luculia and Fuchsia corymbiflora.

Just below this terrace are fine groups of Exochorda grandiflora and Staphylea colchica; Feijoa Sellowiana, which bears delicious fruits every year; Trithrinax brasiliensis, Raphiolepis japonica, a low, thick bush about ten feet through, which is almost covered with thick white flowers in spring; and Tibouchina semidecandra (Lasiandra), with bright purple flowers. Close by a Cryptomeria japonica towers seventy feet high, but is clothed with branches to the ground; near it stands an equally fine Abies nobilis var. glauca.

On the far bank of a small stream stands what must surely be the finest specimen of Sciadopitys verticillata in Europe; it is about fifty feet high, with horizontal branches reaching down to the ground, and perfectly symmetrical at the top. The lowest branches are about fifteen feet long, and the girth of the trunk, at man's height, is about four feet. The needles are in perfect whorls and measure about six inches long. This tree bears cones every year but I was never able to get seeds to germinate.

Perhaps the greatest glory of Monserrate is its collection of Coniferous trees—fine in regard to their great size rather than the extent of varieties. The most noticeable are certainly the Araucarias. There are two examples of Araucaria Bidwillii, one of which is eighty feet high (Fig. 42), thirty feet in girth at the base, and a perfect specimen. It bears cones about the size of a half-bushel basket every year, and a large percentage of the seeds are fertile, but take nearly two years to germinate. Standing on the big lawn is a giant A. excelsa, about ninety feet high, with its lower branches covering the ground about thirty feet around the trunk. It also bears fertile seeds every year. There is a small A. Cunninghamii, still a young plant, and a very fine A. Cookii in another garden belonging to Monserrate. There are three fine Kauri Pines (Agathis australis), only one of which bears cones, which do not, however, contain fertile seeds. Cryptomerias are well represented by several noble trees. C. japonica var. Lobbii stands in a good position at the top of the lawn and is very conspicuous. I have taken some good plants from this tree as the lower branches have rooted and established themselves. There is also a grand C. j. var. elegans in the Rose garden. On the lawn, too, are fine examples of Cedrus Deodara and C. atlantica var. glauca, whose cones give numbers of fertile seeds. Abies Nordmanniana and A. Webbiana are also on the lawn, and are very beautiful trees. In a deep dell, through which flows a small stream, Pinus Montezumae is a striking object, with its dense heads of long, soft, pendulous needles; while P. Ayacahuite, with its large, loose cones, and P. patula make a fine group. A group of Pinus insignis, on a slight rise of ground, is a magnificent sight; the trees are each about 150 feet high, and the largest has a girth of forty feet. Pinus canariensis is of a finer texture, and stands near a giant Eucalyptus viminalis. Sequoia gigantea does not seem to like the salt breezes from the near Atlantic and is only represented by a small plant; but the Redwood, S. sempervirens, does well, as does its neighbour, Thuya gigantea (plicata).

Pinus maritima grows wild on the serra, and is commonly used for rough timber. Turpentine is also obtained from it. Pinus Pinea is also plentiful and forms fine belts of timber trees in suitable situations. Taxodium distichum is beautiful in the autumn with its golden-bronze foliage, and also in the spring, with the tender green of its young leaves. There is also a good specimen of T. d. var. mucronatum, overlooking a small ornamental lake. Cupressus of various species and varieties are abundant, the most common being C. macrocarpa, in many varieties; and there are large specimens of C. lusitanica, especially in an avenue near the entrance gate.

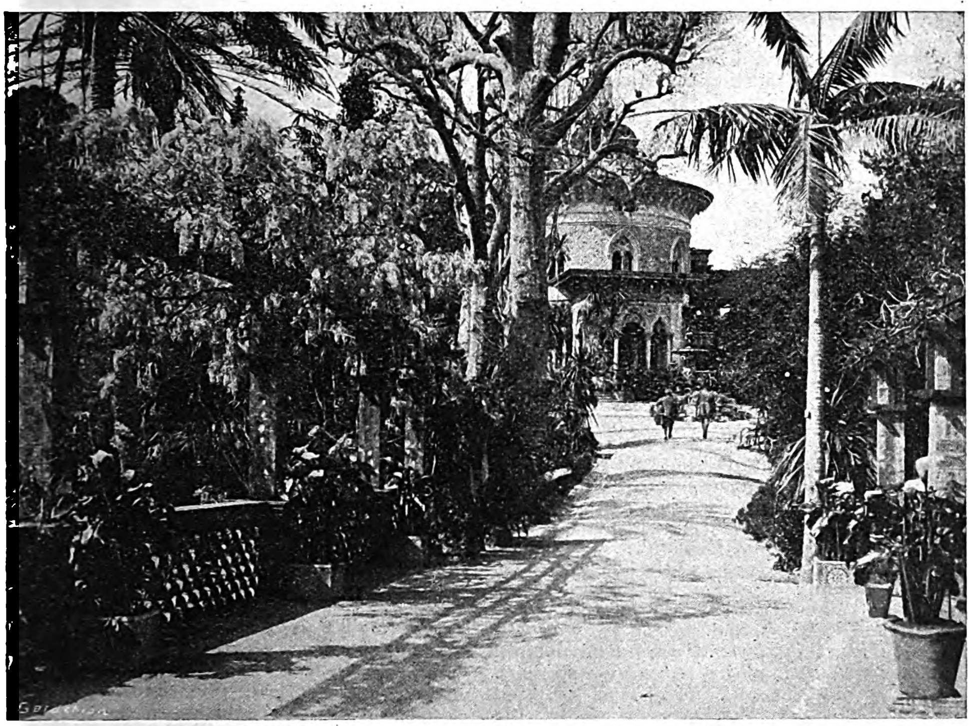

FIG. 44.—MONSERRATE: THE ROMAN CAUSEWAY LEADING TO THE PALACIO.

Near there, too, is a large Pinus longifolia, which is almost deciduous in habit, the needles drying up in the autumn but falling only when the new growth appears in spring. It is a very striking tree, with light-coloured bark, and long, pendulous needles.

On the same lawn as this is a pergola of Cork Oak branches, covered with Wistaria multijuga, both the blue and white varieties, many of the racemes of flowers being nearly a yard long. Some fine examples of Cedrus libanotica border the lawn close by, and in a corner near the carriage drive is a patriarchal Cork Oak, whose long, thick branches are almost covered by the dainty Hare's-foot Fern (Davallia canariensis).

By the side of a large lawn a goodly collection of Magnolias includes M. macrophylla, fifty feet high; M. Campbellii; M. conspicua, M. Soulangiana, M. discolor and several hybrids and varieties. Magnolia grandiflora forms a short avenue of magnificent trees seventy feet high, and fully foliaged to the ground. This avenue affords a superb vista from a Wistaria-covered pergola above a large, old water-tank, on to the lakes far below, and, beyond, up again to the rugged skyline of the distant, rocky serra. There is also the quaint little Magnolia (Michelia) fuscata, with tiny, brownish-purple blossoms, and a perfume like ripe Apples.

Australian plants are represented by large specimens of Grevillea robusta, trees of seventy or more feet high; Metrosideros tomentosa, in huge masses of silvery-grey foliage, fifty feet high and as much through, covered in May with masses of deep red flowers, like bundles of silk threads, and with tangles of adventitious roots almost from the topmost branches; and M. robusta, with small Myrtle-like leaves, represented by very large bushes, which when in flower in the spring are very beautiful.

There are, too, some very large Eucalyptus—one is stated to be the first of its kind planted in Portugal—and two particularly fine specimens of E. Globulus with boles of fifty feet in girth near the ground, and rising sixty feet to the lowest branches, with straight and perfect trunks. Their full height is 135 feet.

Banksia integrifolia, Eugenia australis, E. Jambos, Theophrasta imperialis, a very fine plant; Stenocarpus Cunninghamii, with curious red and yellow flowers borne in winter; Inga (Calliandra) pulcherrima, and many other beautiful and interesting trees are to be seen, while the Mimosa thrives everywhere, where it can be left alone! Gardenias grow freely out-of-doors and flower in the summer. Bignonia grandiflora grows luxuriantly on a terrace wall by the Palacio; while Bignonia buccinatoria almost covers a giant Goa Cedar, making a beautiful display with its large, bright red flowers that hang in festoons from the branches. Bignonia biflora, with large, lavender-coloured flowers, and Tecoma jasminoides, straggling over some old Oaks, also produce a bright effect in the hot days of August and September. Thunbergia grandiflora grows well on a terrace wall and flowers profusely, its large, light blue, flat flowers showing up well against the dark foliage.

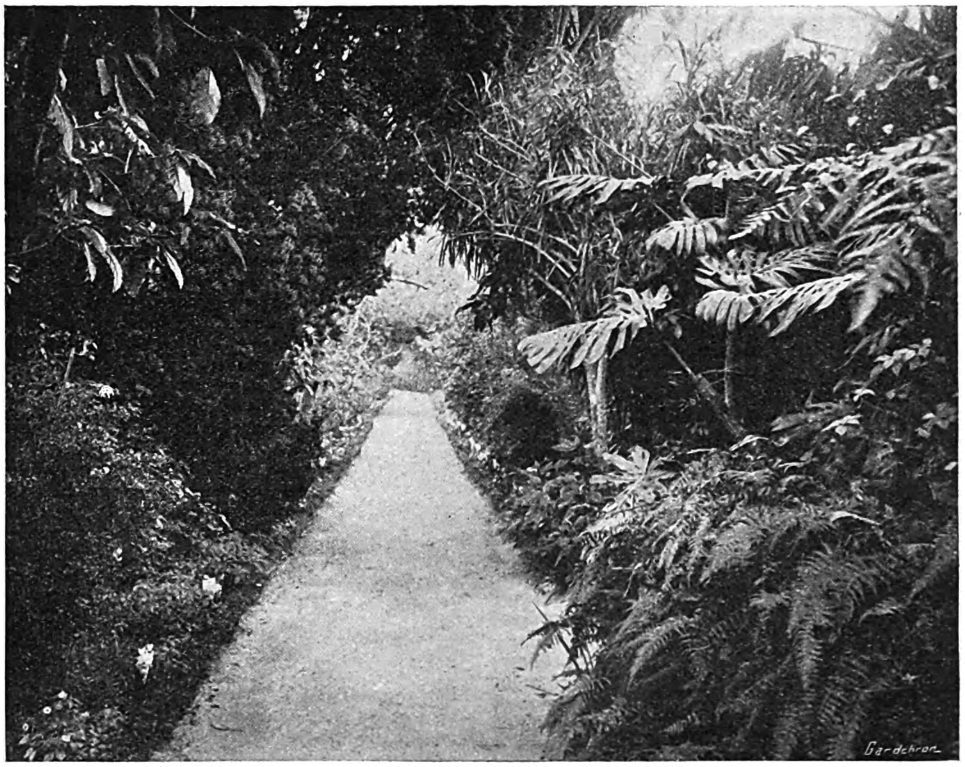

FIG. 45.—MONSERRATE: THE TANK WALK.

The lawns are one of the glories of Monserrate (Fig. 43), as they are the only permanent lawns in the country, and have existed since they were sown sixty or more years ago. They cover about twenty acres and make a fine setting for some of the trees already noted, in addition to large groups of Leptospermums and other Australian plants (Fig. 46), and blue, pink and white Hydrangeas.

The lakes are very charming, as in and around them are collections of various plants. The Papyrus grows freely, as does the smaller Cyperus alternifolius. Nymphaeas cover the water except for a few lanes kept clear by the swans (Fig. 41), while clumps of Nelumbiums stand up boldly and the Aponogeton pushes its dark green leaves and pure white flowers out from the shady sides. Around the edges are groups of Hedychium coronarium, Escallonias, Gunneras, Richardia africana, Iris laevigata, etc. Hedychium Gardnerianum grows practically wild, flowering freely everywhere along the water courses and near the waterfalls.

Yuccas, Agaves and Furcraeas are represented by many good specimens on the lawns and mixed with other plants. Agave Salmiana and A. Frauzosini are particularly fine. Doryanthes Palmeri grows well in large groups; and D. excelsa makes a very striking plant when it is in flower, "like a bowl of flowers," as described by a visitor who wanted to know its name. Cycads are represented by fine plants of Dioon edule, Encephalartos Lehmannii, E. villosum, E. horridus, Cycas revoluta, C. circinalis, Macrozamia spiralis and many other species. On the lawn, standing alone, is a magnificent plant of Macrozamia Macleayi, with a trunk three feet high, two feet thick, and with three large branches, each bearing broad, pinnate, glossy, dark-green leaves six to eight feet long.

Dracaena Draco grows well in a very hot part of the garden, where is, also, a fine group of Yucca Desmetiana (Fig. 47) one plant of which flowered for the first time last year. Tacsonia manicata forms great wreaths of bright scarlet flowers among the branches of some old Cork

Oaks, and among the topmost branches of some very tall Cupressus lusitanica. A large plant of Aloe supralaevis is almost hidden by a huge bush of A. arborescens, which is a glory when hundreds of flower spikes appear on it in early spring; while towering above this is a group of Strelitzia Augusta and Jacaranda ovalifolia.

Palms are very numerous, and mention of only a few of the best must suffice: Cocos flexuosa, C. Romanzoffiana, Washingtonia robusta, the tallest Palm in the garden, about seventy feet high; Kentia Belmoreana, K. Fosteriana, with trunks twenty-five feet high; Phoenix canariensis, P. dactylifera, P. reclinata, with seven well-furnished trunks from one root; Brahea Roezlii, Areca Baueri, A. sapida, Jubaea spectabilis, Seaforthia elegans, Sabal Blackburniana, and Sabal umbraculifera.

The many species and varieties of plants in the garden and serra are almost bewildering. from the huge Quercus Phellos (Willow Oak), the fine and rather rare Q. lusitanica, and the tall Q. Ilex, to the small, low-growing Q. coccifera, whose galls are used for tanning Morocco leather. This grows plentifully here, as does the tall Q. Ballota, which bears the "sweet" or edible acorn. Large groups of Rhododendrons and Azaleas, and Camellias of many species and varieties, form masses of colour in every available corner, and even overflow on to the lawns; and there is a large dell completely filled with Rhododendrons, which, rising up the steep mountain side, join and then mix with the grey, old Cork Oak trees.

In the old stable yard is a fine collection of various plants, including Erythrina caffra, E. Crista-galli, Callistemon rigidum, Citrus trifoliata, Nolina curvifolia, Chamaedorea elatior, etc. The front of the old stable itself is covered with Bougainvillea glabra (with a stem about eighteen inches thick at the base), which appears to be a solid wall of purplish-pink flowers in the late summer. The other walls are covered with Plumbago capensis and Holboellia latifolia; and a small pergola close by is covered with Hexacentris coccinea, that has long racemes of reddish-brown flowers at Christmas time.

Together, with all this wealth of beauty and interest within, there are also many fine views and charming vistas to be obtained from the garden and terraces on to the country below and around. To the westward lies the broad, low valley of Collares, stretching to the sea four miles away, between hillsides covered with vineyards which spread out on either side so far as the eye can see. Beyond, to the horizon, spreads the Atlantic. To the north and east, magnificent views stretch over vineyards and hills and valleys, to Mafra, and to the mountains beyond, to the hills of the famous lines of Torres Vedras, which Wellington fortified against the French armies in 1805, to protect Lisbon and the last remnant of Portugal for the Portuguese. Above the garden, to the south and east, rise the serras, where the water is captured and led into two large, picturesque lakes which supply the gardens with the large amount of water required during the long drought in the heat of summer, and of which the overflow forms the waterfall and cascades in the ravine below. The serras are heavily wooded, but their chief charm lies in the richness of their natural flora.

The upper serras are formed of huge "tors" of granite boulders loosely piled up, on and between which many beautiful wild flowers grow; and all down the steep mountain side, to the famous "Rock of Lisbon" (Cabo di Roca), eight miles away, is filled with glorious colours and wonderful scent; while on the rocks around the lighthouse—the most westerly in Europe—there is a perfect carpet of flowers of many colours and many kinds that from a little distance appears like a beautiful mosaic of the richest colouring in the clear air and golden sunshine of Portugal, with the steep, dark brown cliffs above and the sparkling blue of the Atlantic far below.

Cintra is very picturesque, and is noted for the beauty of its surroundings. There are many gardens, some very old, shady and mysterious, others of great beauty and full of interest; fine timber forests spread along the steep, craggy mountain-sides. Cintra has been praised for many centuries; Byron described its beauty in "Childe Harold," at least some portions of which were written at Monserrate, when it was little better than a ruin. The place was bought from the Portuguese owners about seventy years ago by the late Sir Francis Cook, grandfather of the present owner, who rebuilt the Palacio on the old foundations, and decorated it lavishly in the Moorish style, and laid out and planted the famous gardens, with the help of noted botanists, travellers and English gardeners from Kew. It is a great achievement, and vies with only one other garden of the same kind that I know—La Mortola.

The gardens are visited by thousands of tourists every year, and often tourists from among passengers on steamers calling at Lisbon for a few hours take the opportunity to go out by motor-car, or to Cintra by train, and thence by car, to pay it a visit. *W. O.*

THE CULTIVATION OF NEW ZEALAND PLANTS IN BRITAIN.*

During the summer and autumn of this year (1928), I have been studying the cultivation of New Zealand plants in Britain. My observations have been made in the south-east, south, south-west and north of England, Scotland, the Scilly Isles, Channel Isles and the Isle of Wight. In pursuit of my objective, I have made enquiries in private gardens, large and small, nurserymen's gardens, and public gardens and parks, and have kept an eye upon the ornamental plantations in such places as railway stations, zoos, and sea-fronts. I have thus amassed a great amount of information much too big to be given in any detail in an account of this kind. Only an outline of the subject is here attempted.

Gardens Visited.

Public Gardens: Cambridge University Botanic Gardens; Royal Horticultural Gardens, Wisley, Surrey; Royal Botanic Gardens, Kew; Botanical Garden, Edinburgh.

Private Gardens: Wakehurst Place, Sussex (Mr. Loder); Camla, East Grinstead, Sussex (Mr. Millard); Mr. Ingwerson's, East Grinstead; Ludgvan Rectory, Cornwall (Rev. A. Boscawen); Tresco Abbey, Isles of Scilly (Major Dorrien Smith); Icomb Place, Gloucestershire (Captain Simpson Hayward); Hidcote Manor, Gloucestershire (Major Johnson); Aldenham House, Elstree, Herts. (Hon. Vicary Gibbs).

Nursery Gardens: Mr. De Putron's, Guernsey, and many others.

Public Parks, etc.: At Edinburgh, York, Leeds, Bristol, Southsea, Weymouth, Winchester, Penzance, Dorchester, Isle of Wight, different parts of London, and many other places.

It was not, of course, possible for me to visit all the gardens where our plants are grown. I missed, for instance, Logan, in western Scotland, and Abbotsbury, in Dorset, and many others of which I generally heard too late; yet I think that there can hardly be many (if any) New Zealand plants in these places which I did not see elsewhere. I am under very great obligations to many owners of private gardens and to the authorities at Kew and Edinburgh for the assistance which they gave me in my work. In every case I met with kindness, hospitality, expert guidance, and a wonderful enthusiasm, and I here take the opportunity to express my great gratitude to these kind friends, one and all.

Climate.

The climate of Great Britain is sufficiently like that of New Zealand to make the cultivation of a great part of our flora at least possible, if not always easy. As with us, the west is the wetter and warmer side; the east and south-east are comparatively dry and cold—too cold for many of our best plants. In most of the places I visited in the south-west, and in the Islands, the rainfall is about thirty-five inches annually. It is so low as twenty-four inches in the vicinity of London, and twenty inches in Edinburgh.

The incidence of frost varies extremely. I made enquiries in every garden I saw, with very curious results. In the Scilly Isles frost is "practically unknown"; in Guernsey they expect from 4° to 6°, but in 1927-8 had 16°; at Ludgvan, near Penzance (Cornwall) 12° is not uncommon; in Sussex gardens, well inland, they had 26° last winter; at Aldenham House, north of London, 20° is to be looked for in any year, and in 1895 a frost of 3° below zero was recorded; at Edinburgh from 14° to 16° is usual, and 20° has been experienced. The unusually severe winter of 1927-8 gave me a good opportunity for my studies, since all our plants had been put to a tremendous test. The mere intensity of the cold had most serious effects. At Wakehurst, in Sussex, all the Celmisias out-of-doors were killed, while at East Grinstead, not far off, they had hardly suffered at all. At Wakehurst also a large Hoheria populnea had been killed outright; Sophora tetraptera had been cut at the top, as had Panax arborea, Cordyline australis and Coriaria ruscifolia. A fine specimen of Olearia semidentata had perished. (On the other hand, Arthropodium cirrhatum, which is not hardy in Christchurch, had weathered this winter, growing close to a wall, facing west; and this plant sends up flowers to a height of four feet!) In 1895, all the New Zealand plants and shrubs were killed, even such Spartans as Olearia Haastii, at Aldenham House.

The British gardener has other enemies besides low temperatures. In the Scilly Isles heavy gales and salt spray are very destructive; in all English gardens late frosts, coming after the sap has risen, are apt to do great damage; at Aldenham House, for instance, Gaya Lyallii, after weathering the terrific winter, was killed by a frost of 14° in May of this year. At Edinburgh, where the climate more nearly approaches that of Christchurch, bitter, dry, east winds in March and April are very deadly, and this is thought to be the reason why Cordyline australis (Cabbage Tree) will not flower, although it lives, out-of-doors there.

The main result of these climatic variations is that most New Zealand plants and trees can be grown out-of-doors in the far west; in the Scilly Isles our soft North Island trees and shrubs flourish amazingly. Pohutukawas, for example, and other Ratas, Nikau Palms, all the Pittosporums, Clianthus, Rhabdothamnus, Cordyline indivisa and C. Banksii, the Kauri, the Puka, the Whau, the Puriri, and the Karaka—all these grow and most of them seed themselves profusely. In Cornwall, Devon, parts of Somerset, Dorset and Hampshire, and in the Islands, we see thousands of Cabbage Trees and vast quantities of Flax (Phormium tenax), and the favourite hedge plant is a hybrid New Zealand Veronica. Alpines do not do so well in the west. The climate is generally too dry for the "Mt. Cook Lily" (Ranunculus Lyallii), yet it flowers and thrives in Edinburgh; some people weep and wring their hands over this splendid plant which resists all their efforts to flower it; others would give their souls to be able to grow the Vegetable Sheep (Raoulia eximia) which, I gather, no British gardener has yet succeeded in doing. Our hardier plants and shrubs, such as Acaena, some Olearias and Senecios, are grown everywhere, as will appear presently. On the whole, I think that Edinburgh is the place which most closely resembles the South Island of New Zealand (eastern side) in respect of rainfall, frost and general climatic conditions, and certainly, for this and other reasons, it is here that the visitor finds the best all-round representative collection of the plants of New Zealand, while, in respect of the North Island plants in general, and the forest trees in particular, the Tresco Abbey plantations and gardens easily surpass all other collections.

Methods of Importation.

Several of the growers of New Zealand plants have visited the country and brought back plants or seeds with them (*e.g.*, Major Dorrien Smith and Captain Simpson Hayward), and this is the only quite satisfactory method of importing living plants; the owner can look after them himself on the voyage, see that they are properly stored, and get them away from the docks

---

*By Professor Arnold Wall, Canterbury College, Christchurch, N.Z. Reprinted from *The Press*.

without delay. Even when they are put in charge of someone on the ship delays at this end are apt to be fatal. And on one occasion, a whole case of plants was destroyed, though in the owner's charge, by a well-meaning deck-hand who applied his hose (of salt water) to the whole lot! Many plants are sent to order by nurserymen in New Zealand. I saw one such consignment (to Mr. Loder) and nearly all the plants had perished—probably owing to careless or inefficient packing. I am assured by one of the most sucessful growers that the only satisfactory method is by seed. The imported plants, while they withstand the change of season surprisingly well, never establish themselves quite so happily as when they start fresh from the seed over here. Many people complain, however, that the seeds sent to them from New Zealand do not germinate at all, or only after an interval of perhaps two years. Major Dorrien Smith, who has had great experience, both in growing plants brought over by himself, and in growing from seeds, assured me that seeds, especially those of any Composite plant, cannot be relied upon to germinate here, unless they are packed in dry sand and in airtight tins.

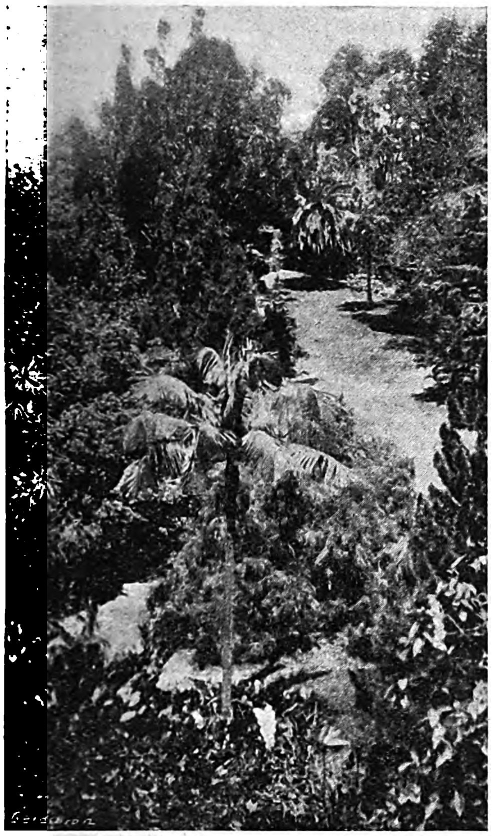

FIG. 46.—MONSERRATE: AUSTRALIAN PLANTS AND SEAFORTHIA ELEGANS.

English growers ought by now to know a great deal about the matter, as some of our trees and shrubs have been cultivated in Britain for a very long time. Plenty were sent (or brought) to Tresco Abbey (Scilly Isles) in the 'sixties and 'seventies, and are now very large trees, while others were introduced there from Kew as early as 1847. It would be interesting to know whether any of our plants were grown in the eighteenth century as a result of Cook's and other early voyages. Flax (Phormium) was certainly grown at Bordeaux by 1790. I have sometimes been asked whether it might be possible to grow our Flax commercially. I thought not, and am told that one Irish peer has tried it, unsuccessfully, having planted "a whole hillside" with it. Naturally, if the thing could be done at all, swampy ground would have to be chosen.

Plants in General Cultivation.

(a) South and south-west and Islands:—As already noted, the visitor to Cornwall, Devon, and the south-west coast, will see thousands of Cabbage Trees (here always called "Dracaenas") and great quantities of Flax (Phormium) everywhere. The commonest garden hedge plant of Cornwall is a hybrid New Zealand Veronica. Griselinia littoralis is very frequent in all sorts of gardens, public and private, and I have also seen quite a lot of Olearia nitida (more than one form), Piper excelsum, Olearia Forsteri, O. macrodonta, Dicksonia (Tree Fern), Sophora and various hybrid Veronicas. Phormium is supposed to be tender, but it grows well (not flowering, however) at Aldenham. According to Robinson (the *English Flower Garden*) the Veronicas are generally not quite hardy, except V. Traversii, but this is not at all borne out by my experience. Senecio laxifolius is much grown.

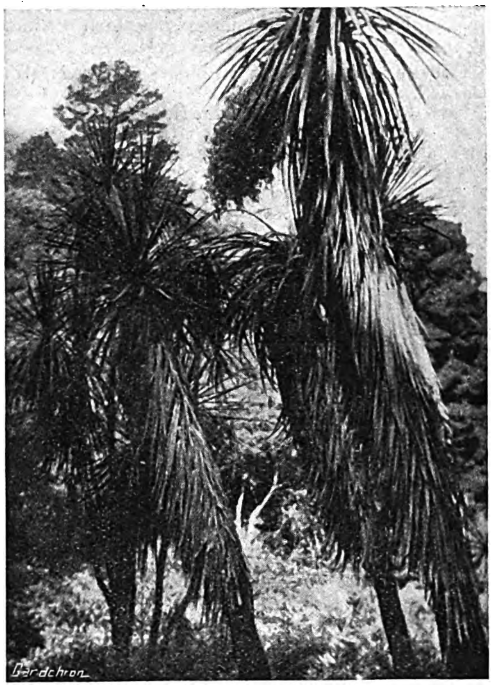

FIG. 47.—MONSERRATE: YUCCA DESMETIANA.

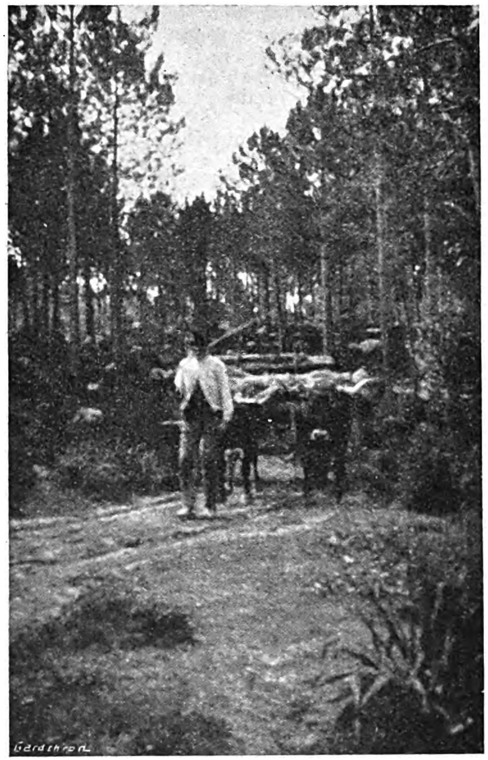

FIG. 48.—MONSERRATE: OX-CART IN THE UPPER SERRAS. (see p. 90).

Those who are interested in this district and its gardens will find an admirable guide in "Some New Zealand Trees and Shrubs in Cornish Gardens," published in the *Journal* of the Royal Horticultural Society in 1923, by the Rev. A. Boscawen. The photographic illustrations are excellent and most instructive.

I may add that I saw plenty of Cabbage Trees and Flax in Naples, Rome and elsewhere in Italy, and observed with some amusement that whenever the symbolic she-wolf which lives in a cage on the Capitol at Rome looks out of her back door she can see only a large clump of Phormium tenax.

(b) Britain in General.—The two commonest of our plants in Britain are Veronica Traversii and Olearia Haastii. For example, I noted this Olearia in Kensington Gardens and elsewhere in London; in the public gardens in Princes Street, Edinburgh; in the Borough Gardens at Dorchester; in Durham Cathedral Close; in the grounds of Camden House, Chislehurst, Kent, where the dethroned Emperor Napoleon lived for a time; at Balquhidder Railway Station and at Ballachulish in the western highlands; in Victor Hugo's garden in Germany—after which I kept no count of it. Everywhere this plant blooms profusely, makes a splendid show and is a great favourite; most nurserymen stock it. After these two, perhaps the most universally grown plants are Cassinia fulvida, various Veronicas, particularly V. buxifolia, V. pinguifolia, V. cupressoides, and V. Hectori; Acaena inermis, A. Buchanani and others in rock gardens; Raoulia australis; and Muehlenbeckia complexa, which last was a great surprise to me as we hardly think of it as an ornamental plant in New Zealand. There is plenty of this in the Embankment Gardens, near Charing Cross Station, and at Tresco Abbey it has grown, as a climber, to an immense and almost incredible size. Other plants which I have seen pretty often are: Aciphylla Colensoi and A. squarrosa; Hypolepis millefolium (curiously called New Zealand Bracken); Veronica Hulkeana (not so frequent as one would expect); Senecio Monroi (or S. compactus) and S. Greyii; Pittosporum crassifolium; Veronica angustifolia, Cotula squalida; Nertera depressa; Pittosporum eugenioides and P. tenuifolium and Olearia Forsteri.

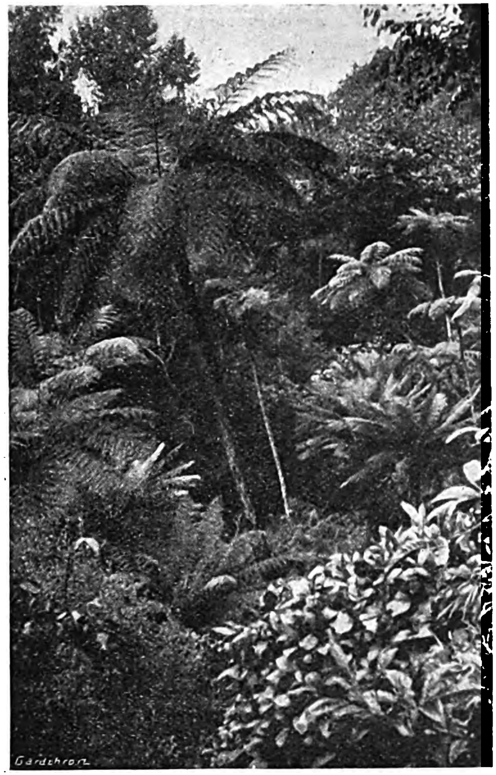

FIG. 49.—MONSERRATE: THE NOOK.

(*To be continued.*)

THE GENUS PRIMULA.

(*Continued from p.* 74).

PENDULIFLORA (Franch.). Pendulous-flowered P. (Soldanelloidae.)

A DECIDUOUS sub-species of P. nutans (Fr.), of robust, tufted habit, with oval-oblong leaves one-and-a-half inch to two-and-a-half inches long, gradually tapering into a narrow, winged stalk; margins furnished with remote, blunt teeth and edged with white hairs; both surfaces covered with white hairs, especially on the nerves. Flower stem four to eight inches tall, erect, slender, smooth, or covered with white, meal-producing hairs. Flowers in a rather dense head, drooping, of an intense blue-violet or deep blue colour, fragrant. Corolla about five-eighths-of-an-inch across; lobes broadly heart-shaped, notched; tube cylindric, about three-quarters-of-an-inch long, including the corolla. Flowers in September. Not in cultivation.

Grows in damp mountain pastures on Mount Ma-eul-Chan, in north-western Yunnan, at 10,500 feet above sea-level.

Culture: Good fibrous loam and peat, with protection from damp in winter, are indicated.

PETIOLARIS (Wall). Himalayan Primrose (Petiolaris-sonchifolia.)

A beautiful perennial species of densely tufted habit with usually more or less elliptic leaves, frequently tapering to winged stalks, in all from two to nine inches long; margins furnished with sharp teeth; both surfaces rugose and non-mealy. Flower stem obsolete; flowers numerous, on slender stalks springing from the centres of the rosettes. Corolla pale purple, pink or white, three-quarters- to one-and-a-quarter inch across, flat, egg-shaped, bifid or edged with several sharp teeth at the tip; tube funnel-shaped, longer than the calyx. Flowers in autumn and winter.

Grows in damp, cool situations in the Himalayas from Simla to Bhutan, at from 4,000 to 12,000 feet above sea-level.

Culture: Good rich loam and Oak or Beech leaf-soil, in a cool, half-shady spot, should suit it.

PETITMENGINI (Bonati). Petitmengin's P. (Obconica.)

An apparently beautiful, deciduous, perennial plant with a fairly woody rootstock and tufts of oval-oblong, blunt, membranous leaves from two to three inches long, heart-shaped at the base, borne on slender stalks two to three inches long, clothed with long hairs; margins entire, or obscurely lobed; both surfaces densely clothed with fine hairs, those on the underside being the longer. Flower stems one to two, tall, erect, hollow, downy, bearing a terminal umbel of three to five rose-coloured flowers on slender stalks of unequal length. Corolla concave, about three-quarters-of-an-inch across, divided into five rounded, blunt, cleft lobes; tube cylindrical, about three-eighths-of-an-inch long, twice as long as the calyx.

Grows in the clefts and hollows of shady limestone cliffs near Setzeoudy, in the region of Pinchwan, Yunnan, western China.

Culture: As for P. obconica, of which it is considered a sub-species.

PETROCHARIS (Pax et K. Hoffm.). Imbricate P. (Minutissimae.)

A very dwarf, densely tufted perennial, forming wide patches composed of rosettes of imbricated leaves three-eighths- to five-eighths-of-an-inch long when fully developed, with elliptic, pointed blades, usually tapering somewhat abruptly into a rather broad stalk, or at times nearly stalkless; margins entire, or furnished with broad, obscure, blunt teeth or small lobes; both surfaces slightly downy and non-mealy. Flower stem about one inch tall, immersed in the foliage and bearing from one to three terminal, rose-coloured blossoms on slender stalks under one-eighth-of-an-inch long. Corolla about a quarter-of-an-inch across, with broadly heart-shaped lobes; tube cylindrical below, dilated upwards, about a quarter-of-an-inch long. Flowers in April and May. Not in cultivation.

Grows in open situations among dwarf herbage on the mountains near Wen-tschuan-hisen, in the Province of Szechuan, western China, at about 13,000 feet above sea level.

Culture: As for P. minutissima. *A. W. Darnell.*

(*To be continued*).

GARDEN MANURES FOR AUGUST.

WHILE plant nutrition is a more or less continuous process, and the absorption of food from the soil necessitates the preparation of further supplies to maintain this continuity, August, the month of ripening crops, cannot be regarded as a time when intensive manuring on a large scale calls for attention. For some crops and under certain conditions of cultivation, circumstances may render it advisable to use some quick-acting fertiliser, such as nitrate of potash, to help finish a fruit crop; or nitrate of soda to maintain growth in a green crop; applications of liquid manure to various growing vegetable crops; or even a sprinkling of superphosphate or bone-meal to ground cleared of summer crops and being prepared for the main planting of Cabbages; but it may be stated that this month calls more for the study of the future needs of the soils under our management than for the immediate application of fertilisers. It is true that many pot plants are just at that stage of development when, in preparation for winter flowering, liberal applications of manure will be of the utmost benefit, but growers of pot plants are always alive to this necessity, and many of their cultures have not yet reached opulent growth, whereas the generality of outside crops are approaching maturity.

It may, therefore, be profitable to consider the value and uses of some of the less discussed elemental plant foods, and sulphur as a plant-nutrition agent opens up interesting ground, for this element has perhaps a more important influence on crop production than is usually assigned to it.

Sulphur affects plant nutrition in three ways; directly as a plant food, and indirectly as an assistant food carrier, and as a combatant of various plant diseases which restrict the capability of the plant to absorb food. As an assistant food carrier its work is well exemplified in sulphate of ammonia and sulphate of potash. That it possesses unusual fungicidal properties is also well-known, and most of the standard fungicides have sulphur as a base, but its action as a fungicide is not completely uniform and may depend on other factors. Its effectiveness in practical use is influenced by its state of division, and for the successful control of mildew it is an important point that the particles of sulphur should be sufficiently small to remain in aerial suspension for a considerable length of time, otherwise its tendency is to drop quickly to the ground and not collect gradually on the leaf surfaces under treatment. Again, its action is more pronounced in high temperatures than in low temperatures, and strong sunlight appears also to have an accelerating effect. Many users of lime-sulphur solutions have observed lasting results following its application, and it is not impossible that this may be due to the more intensive action of sulphur under strong sunlight.

But apart from the final action of sulphur or sulphur compounds as fungicides, there is some evidence to show that there may be some sulphur residues which serve the purpose of direct food supplies to the plant, or assist in their preparation in the soil. French growers have found that if fine sulphur to the extent of from 100 kg. to 200 kg. per hectare (=80 lbs. to 160 lbs. per acre) is incorporated with the soil, productivity is sensibly increased; but whereas its action is insignificant on a sterilised soil, on a non-sterilised soil its action is very marked. One can deduce from this that sulphur has a beneficial influence on the bacteria of the soil, augmenting the quantity of nitrogen assimilable by the activity it communicates to the ammonia-creating bacteria and nitrifying ferments.

It is well-known that this action can only manifest itself in soils charged with the humus that is so necessary for the normal development of bacteria. On the other hand, by means of bacterial action, sulphur can oxidise itself in the soil and become sulphate of ammonia. Under the influence of certain anaerobic microbes sulphate of ammonia can transform itself into hydrogen and sulphuric acid; it acts then as a partial steriliser of the soil, defending the useful bacteria from their natural enemies the protozoa. But sulphate of ammonia acts differently, according to the soil in which it is found; it can act by itself if the soil is poor in sulphate and if the soil is calcareous; in combining with calcium, it augments the proportion of assimilable potash; but if the soil is very deficient in calcium it forms soluble salts with manganese, potash, iron and magnesia. Sulphate of ammonia, coming from the oxidation of sulphur, acts also on the mineral phosphates and renders them soluble in water. If, nevertheless, the quantity of sulphur is exaggerated in a non-calcareous soil, the sulphate of ammonia formed turns the soil acid, to the detriment of vegetation.

In the environs of Villescresnes, Mandres, large tracts of Roses are grown in loam containing little calcium; the growers used large quantities of sulphur to combat fungus diseases until some of the areas became nearly unproductive. On analysis, it was found that the soil was intensely acid, and it was only by heavy dressings of lime that it was again made productive. Numerous experiments with sulphur have been made during the last few years. Dr. Dudisch, of Pontiers, recorded an increase of one hundred per cent. in the Potato crop when cut sets were powdered with sulphur, and the Comptoir Parisien has obtained excellent results in its field experiments at Sartrouville by employing sulphur in the cultivation of Spinach, Peas, Potatos, Cabbages, Onions and Carrots. The various phenomena of chemistry and biology appertaining to the action of sulphur have been studied in masterly fashion by Mon. Kayser, and there can be no doubt that this element may be called upon to render very great service to cultivation. *W. Auton.*

JAM MAKING AND FRUIT BOTTLING.

FOR the home preservation of fruits, it should be noted that all fruits to be preserved should be quite sound, and that, if a large quantity is to be handled, it should be graded into various sizes and the riper fruits put aside for jam- or jelly-making, and the rest used for bottling or canning.

For bottling, the condition of the fruits should be firm ripe, except in the case of Gooseberries, which are usually dealt with when quite under-ripe. All fruits should be bottled in syrup, as fruits bottled in water lose much of their flavour, and after a few months become bleached and unattractive. The syrup is made by dissolving 8 ozs. to 12 ozs. of sugar in each pint of water, bringing this solution to boiling point, and allowing it to cool before use.

Red and black varieties of Cherries are best for preserving. If bottled in water, the flavour of the stone becomes strong, and the flesh is tasteless and unattractive. For most varieties, a syrup, using 8 ozs. of sugar to a pint of water, is sufficient, but for the Morello Cherries 12 ozs. of sugar should be used. As most varieties of Cherries have a relatively low acidity, the temperature of the water in the steriliser should be raised slowly to 190°F., and maintained at this temperature for fifteen to thirty minutes. For Cherry jam, the best varieties to use are Morello and May Duke, and all or part of the fruit should be stoned. Small Cherry-stoners may be purchased at the ironmonger's for a few pence.

In regard to jam-making, after the usual preparation of the fruits, put them into a freshly-cleaned preserving pan. For hard fruits add sufficient water to start the cooking—about one pint to 10 lbs. of fruits is the average quantity. For soft fruits, add no water. Use white granulated sugar, allowing ¾ lb. to 1 lb. of sugar to each pound of fruits, the larger amount in the case of unripe fruits. First stir over a moderate heat until the texture is broken down. Then add sugar to the fruits and stir until all the sugar is dissolved. Then boil rapidly until the jam sets when tested. The preserving pan must be large enough to allow of rapid boiling without fear of boiling over. Stir to prevent burning. Test the jam frequently by placing a little on a cold plate. If, on cooling, the consistency is firm, the jam has boiled sufficiently. The more quickly the jam is boiled the better will be its flavour and colour. If the jam is boiled too long its settling properties are destroyed.

Pour then into heated jars and place waxed papers on the surface of the jam while it is hot. Lay a sheet of clean paper over all the pots to prevent dust and fungus spores settling, and when the jam is cold tie down tightly with parchment paper and store in a cool, dry place.

In the case of Raspberries and Strawberries, a small amount of citric or tartaric acid should be added in order to make the jam set more rapidly; say ½ oz. to every 8 lbs. of fruits. The acid should be dissolved carefully in a small amount of water and should be mixed thoroughly into the jam before the addition of the sugar. If acid fruit juice is used, about one pint should be added for every 4 lbs. of fruits. Jam may not keep if over-ripe fruits are used, or if less than ¾ lb. of white granulated sugar to each pint of fruits is used. It may not keep if it is insufficiently boiled, or if it is kept in a damp cupboard or in too warm a place.

HOME CORRESPONDENCE.

The Bulb Industry in Holland.—It seems to me that in your notice of Mr. E. H. Krelage's statement on the Dutch bulb trade (*The Gard. Chron.*, p. 356, Vol. LXXXV), justice is hardly done to the real facts. You imply that were English growers seriously to enter the field of bulb production, they might expect to produce a reasonable share of the 43,000,000 kilos of bulbs which formed the Dutch export in this article for 1928. You state quite truly that Darwin Tulips and Daffodils can be grown as well in this country as in Holland, that certain Dutch growers have settled in districts already pioneered by our own people, and that we take an honourable place as raisers of Daffodils. But all this does not prove that we can compete with the Dutch in the mass production of bulbs. To produce bulbs at a cheap rate, true to name, of even grade, and free from disease, is a great discipline. The bulb gardens of Haarlem, which are reclaimed from waste, are most costly to produce, and the only chance of success, —a competitive price—is to cultivate in the most efficient and economical manner possible. It is just here that the Dutch are incomparable. To put things into prepared ground in rows and take them out again when the proper moment arrives, and to do all the other things which bulb culture demands, fits to perfection the methodical genius of the Dutch. Moreover, have they not the acquired tradition and technique of three hundred years of experience in the bulb field? We are apt to forget what the Dutch have done. Where, eighty years ago, a decent Hyacinth bulb cost 5s., to-day we can get it for 6d., a result we owe to them. It is the reaction of the Dutchman to his land environment that counts—his relation to the soil. To live in and pay for making Holland, he must export, and this compels him to be adaptable; to find outside markets, and to produce at competitive prices what those markets require. If we changed countries with the Dutch lock, stock and barrel, it is to be expected that within five or ten years England would be exporting to Holland the 16,000,000 kilos of bulbs which at present go the other way. Whether this would continue is another matter. Residence in England might, in time, make the Dutchman easy-going. *F. W. Oliver.*

SOCIETIES.

ELSTREE AND DISTRICT.

July 20.—The exhibition of the above Society was held in Aldenham Park, Elstree, and was one of the best held under its auspices.

There were four groups of cut Roses, arranged on a space twelve feet by four feet. The exhibits of the three prize winners were all that could be desired. Messrs. Chaplin Bros., Ltd., Waltham Cross, won first prize and the Silver Challenge Cup with a superbly handsome group of high quality blooms charmingly arranged. There were masses of such standard sorts as W. E. Chaplin, Dame Edith Helen, Mrs. Henry Morse, Mrs. A. R. Barraclough, Golden Emblem, Los Angeles, Lady Inchiquin, Conqueror and Mrs. Henry Bowles. A good second was seen in the group of Messrs. R. Harkness and Co., Hitchin, who had many remarkably handsome blooms, but they lost in arrangement. Messrs. Frank Cant and Co., Ltd., Colchester, were placed third.

A new class for a decorated table of Empire fruits found only one entrant; this exhibit was arranged on a space ten feet by four feet. First prize was well won by Mr. W. H. Lees, Queen's Road, Watford, who staged superb Alicante, Canon Hall Muscat, Black Hamburgh and Gros Colmar Grapes, Australian examples of well-grown Apples, Kentish Cherries, Pears, West Indian Pineapples, and a host of other superb fruits that were much admired. A splendid innovation.

There were several classes for cut Roses, the principal class being for twelve Roses, distinct. Mr. H. F. Spicer, Hitchin, was first out of four competitors, showing good examples of George Dickson, Candeur Lyonnaise, Mrs. Henry Bowles, Mdlle. Louise Crette, Mrs. A. R. Barraclough, Mrs. G. Norwood, Mrs. Charles Lamplough and Dame Edith Helen. Mr. J. N. Hart, Little Heath, Potters Bar, was a good second, and Mr. W. Martineau, third.

For a bowl of Roses there were five entries. Mr. Hart was first with a pretty arrangement; Mr. H. E. Dunhill, Harpenden, second, and Mr. Spicer, third. In the class for a vase of Roses, Mr. Spicer was first; Mr. Hart, second, and Mr. Dunhill, third. Of the four entrants in the class for three vases of cut Roses, Mr. Spicer was a grand first, showing splendid examples of Mrs. C. Lamplough, Mrs. George Marriott and Dame Edith Helen. Mr. Hart was a close second, and Mr. R. C. Peake, Redbourn, third.

Sweet Peas are always a great feature at this show, the competitive classes running down the whole length of one side of the large tent. The chief class was for twelve distinct varieties, twenty sprays of each. First prize and the Silver Challenge Cup was won by S. Wallrock, Esq. (gr. Mr. M. Holloway), The Manor House, Stanmore, who showed Sweet Peas at their best. His varieties were Mrs. A. Searles, Crusader, Powerscourt, Gold Crest, Youth, Charming, Susan, Model, Grenadier, Magnet, Bluebell and Royal Mauve. Mrs. Carl Holmes (gr. Mr. W. Penton), The Node, Welwyn, who was second, had consistently good blooms of popular sorts; third prize was awarded to Mrs. H. E. Dunhill, last year's Cup winner. A smaller class for six vases of Sweet Peas produced five entrants. First prize was won by Mrs. Duveen, Broadway, Limpsfield, who had a superb exhibit; Mr. H. Pitt, Boxmoor, was a good second, and Mr. P. L. F. Cook, The Bell House, Hayes, third. The first prize in this class also secured a Challenge Cup. The six entrants in another class for six vases, distinct, and not more than twelve sprays of each variety, made a splendid display. Mr. Wallrock was again first, Mrs. Carl Holmes, second, and Mrs. H. E. Dunhill, third, all showing extremely well. Mrs. Dunhill was first in the class for a vase of pink Sweet Peas, and Mr. Wallrock first in the classes for one vase of white, crimson or scarlet, lavender, cerise, or scarlet-cerise, and cream, buff and ivory—an excellent record.

There were four entrants in the dinner table decoration class, confined to Sweet Peas. First prize was awarded to Mrs. Veitch, Cassiobury Drive, Watford, who used a rich orange coloured Sweet Pea effectively. A very dainty table secured second prize for Miss F. J. Jones, Watford. Another class in which the kind of flower used was left to the exhibitor's discretion brought forward so many as eight competitors. First prize was awarded to Miss F. E. Tutte, Cross Road, Bushey, for a decoration made up of Gypsophila elegans, pink Cornflowers, etc. A pretty table of Iceland Poppies secured second prize for Miss R. J. Stevens, Radlett, and, with Roses, Mrs. E. Carpenter, Kings Langley, was placed third.

There were many very interesting competitions, far too numerous for us to mention, but, generally, their character and quality were good.

This splendid show would be incomplete without one of those noteworthy exhibits of vegetables coming from the gardens of Aldenham House, in the name of the Hon. Vicary Gibbs, whose able gardener, Mr. Edwin Beckett, again excelled. There were about 250 dishes of vegetables of almost every conceivable kind arranged in most artistic fashion and in splendid form and condition, notwithstanding the trying season. Too much praise cannot be given to this exponent of high culture, and the awards of a Gold Medal, a Cup for the gardener and the thanks of the judges, were well merited.

The trade supported the show in excellent fashion. Messrs. L. R. Russell, Ltd., staged exotic plants in fine form, including a number of Water Lilies (Gold Medal); and Messrs. William Cutbush and Sons, clipped trees, Roses and herbaceous plants (Silver-gilt Medal). Silver Medals were awarded to Mr. W. A. Collier, Messrs. W. Kemp, Mr. Carlile, Mr. Amos Perry, Mr. J. H. Pemberton and Messrs. James Carter and Co.

Mr. W. J. Pritchard, the Hon. Secretary, merits praise for the excellence of the arrangements of the show.

HARROGATE SHOW.

The Horticultural Section of the Royal Show, held at Harrogate on July 9 and following days, under a dull sky which threatened rain, was a very successful event. The popularity of this show is most marked, and exhibits from all the leading trade growers combined to make it a greater success than ever. Princess Mary made a long stay, and closely examined the various exhibits in the two large marquees. From the time of the opening until the close the tents were crowded; in fact, so great was the crowd late in the afternoon of the first day that the visitors had to be admitted in relays.

Although the competitive classes were not numerous, the prizes were liberal, and the demand for space from trade growers was heavier than in previous years.

In class 1, for a group of miscellaneous plants in and out of bloom, Messrs. J. Cypher and Sons, Cheltenham, were first, with a delightful exhibit of well-coloured Codiaeums, Dracaenas and Thunias, Laelio-Cattleyas, Odontoglossums, Liliums and many other handsome plants. Mr. T. M. Petch, Great Horton, was second.

Messrs. Blackmore and Langdon were placed first for a collection of Delphiniums, and also for a group of tuberous Begonias, with flowers of exceedingly high quality and arranged in a most artistic manner.

Messrs. Maurice Prichard and Sons, Ltd., Christchurch, led for a group of aquatic plants; second, P. Gardiner, Craven Nurseries; third, Messrs. Bowell and Skarratt, Cheltenham. This was a most attractive and interesting class. For a collection of hardy perennials and cut blooms, Messrs. Bees, Ltd., were first, with a very artistic and representative exhibit; Messrs. Harkness and Sons, Bedale, being placed second; and the Gayborder Nurseries Melbourne, third; while for a collection of Lupins, Messrs. Harkness and Sons were first, and Messrs. J. F. Rashley and Co., second.

Messrs. C. Engelmann, Ltd., led for a collection of cut sprays of Carnations with blooms of fine quality; while Mr. Horace Lakeman, Thornton Heath, secured the premier award for a collection of border Carnations.

Messrs. R. Bolton and Son showed grand flowers in splendid condition in their first prize collection of Sweet Peas; while in the keenly contested class for a collection of cut Roses, Messrs. Wheatcroft Bros. were first; Mr. Charles Gregory, Chilwell, second; and Messrs. William Lowe and Sons, Beeston, third.

Medal Awards.

Large Gold Medals.—To Messrs. Allwood Bros., for Carnations; to Messrs. Sutton and Sons, for a marvellous exhibit of Sweet Peas; to Messrs. Alex. Dickson and Sons, for Roses and Sweet Peas, staged in great variety and of wonderful quality; to Messrs. Kent and Brydon, for formal garden; to Messrs. Backhouse Nurseries, Ltd., for a rock garden; to Messrs. Broadhead, for a rock garden; to Mr. H. Lakeman, for one of his wonderful exhibits of border Carnations; and to Studley College for a grand collection of fruits and vegetables.

Gold Medals.—To Messrs. Bees, Ltd., for Delphiniums; to Messrs. R. Bolton and Son, for Sweet Peas; to Mr. W. Brown, for Roses and herbaceous plants; to Messrs. Frank Cant and Co., for Roses; to Messrs. J. Forbes and Son, for Pentstemons, Carnations and other choice plants; to Messrs. Conways, Halifax, for a rock garden; to King's Acre Nurseries, Ltd., for pot fruit trees; to Mr. Thomas Robinson, for Roses; to Mr. Maxwell H. Hatcher, Rawdon, for Orchids; to Messrs. Maurice Prichard and Sons, Ltd., for alpines and other hardy flowers; and to Mr. George Marriott, for Roses.

Silver-gilt Medals.—To Messrs. Bakers, Messrs. Hewitt, Ltd., Messrs. Kelway and Son, Messrs. Laxton Bros., Messrs. Stuart Low and Co., Messrs. Artindale and Son, Messrs. Whitaker and Wilson, Messrs. B. Cant and Co., and to the Harrogate and District Horticultural Association.

Silver Medals.—To Messrs. G. Gibson and Co., Messrs. Jarman and Co., Messrs. William Lowe and Sons, Messrs. Maxwell and Beale, and to Messrs. Toogood and Sons.

ROYAL HORTICULTURAL.

July 30.—Although there was a small show at the new Horticultural Hall, Westminster, at this fortnightly meeting of the R.H.S., it was very interesting in the variety of good things on view. The principal feature was the magnificent Gold Medal exhibit of pot fruits, beyond which the Fruit and Vegetable Committee had little to require attention. There were two good exhibits of Orchids, and the Committee recommended two First Class Certificates and one Award of Merit to novelties. Seasonable flowers were shown in considerable variety, the chief subjects being herbaceous Phloxes, Sidalceas, Roses, Carnations and Gladioli. The Floral Committee recommended six Awards of Merit to novelties, and selected five other new varieties for trial at Wisley.

Orchid Committee.

Present: Sir Jeremiah Colman, Bart. (in the chair), Mr. Gurney Wilson (Hon. Secretary), Prince Shimadzu, Mr. Fred J. Hanbury, Mr. A. Dye, Mr. E. R. Ashton, Mr. R. G. Thwaites, Mr. Fred K. Sander, Mr. A. McBean, Mr. T. Armstrong, Mr. Charles H. Curtis, Mr. S. Flory, Mr. J. Shill and Mr. H. G. Alexander.

First Class Certificates.

Miltonia gattonensis, Exbury var. (*M. Bleuana* × *M. Charlesworthii*).—A particularly lovely Orchid that has previously gained an Award of Merit, and was now shown in fine style, the plant carrying two spikes and a total of ten large and exquisitely beautiful flowers. The blooms are white with a golden disk that shades into the golden-brown of the base of the mask, and this in turn shades into a carmine-rose area beyond which a few carmine-rose and brown lines extend into the white area. Shown by Lionel de Rothschild, Esq. (Orchid Grower, Mr. B. Hills), Exbury, Southampton.

Laelio-Cattleya Sargon var. Vesuvius (*C. Hardyana* × *Laelio-Cattleya Lustre*).—This very handsome Orchid is probably the best of the numerous Sargon varieties, and belongs to the gloriosa class. The broad sepals and petals are rich, deep purplish-mauve with a few fine veins of deeper mauve. The broad lip is rich royal purple with old gold veins and brownish shading in the throat. The flowers are of splendid size and fine substance: Shown by Messrs. H. G. Alexander, Ltd.

Award of Merit.

Cattleya Gladiator (*C. Dowiana* × *C. Gladys*).—A distinct and striking hybrid with purplish petals, and sepals that are mottled with greenish-yellow on a rosy-purple ground. The lip has a purple and frilled apex and a wide golden area towards the base, edged with purple, and heavily veined with dark purplish-brown over the centre and in the throat. Shown by F. J. Hanbury, Esq. (gr. Mr. Farnes), Brockhurst, East Grinstead.

Groups.

A dozen flowers of Laelio-Cattleya elegans on one spike was a leading feature in the group set up by Messrs. Sanders. This group also contained Stanhopea oculata with two pendant, fragrant spikes, Vanda coerulea, Phalaenopsis Rimestadiana, Odontonia brugensis, with two score of its mauve flowers, Dendrobium regium, Cattleya Hardyana and Cypripedium Godefroyae var. leucochilum.

Messrs. Charlesworth and Co. displayed a pretty group of Orchids and showed Dendrobium Dalhousianum, Sophro-Laelio-Cattleya Adonis, Odontioda Nola, Odontonia Laguna, Coelogyne Rumphi, Maxillaria venusta, Cattleya Hardyana, Cypripedium Curtisii, Oncidium Papilio and numerous fine spikes of brightly coloured Odontoglossum hybrids.

Floral Committee.

Present: Section A.—Mr. H. B. May (in the chair), Mr. J. F. McLeod, Mr. A. Turner, Mr. Courtney Page, Mr. G. Churcher, Mr. J. T. West, Mr. A. Vasey, Mr. Hugh Dickson, Mr. M. C. Allwood, Mr. W. B. Gingell, Mr. D. Ingamells, Mr. D. B. Crane, Mr. C. E. Pearson, Mr. G. W. Leak, Mr. W. Haskett and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. C. T. Musgrave (in the chair), Mr. G. Reuthe, Mr. E. A. Bowles, Mr. G. W. Baker, Mr. F. G. Preston, Mr. L. R. Russell, Mr. A. Bedford, Mr. T. W. Taylor, Lady Beatrix-Stanley, Mr. Mark Fenwick, Mr. E. H. Wilding, Mr. E. Marsden-Jones, Mr. T. Hay, Mr. Reginald Cory, Mr. W. B. Cranfield, Sir W. Lawrence, Bt., Mr. Clarence Elliott, Mr. George Yeld and Mr. N. K. Gould, Secretary.

Awards of Merit.

Allium flavum.—A graceful little species which was introduced from Italy in 1759, and is figured in *Bot. Mag.*, t. 1,330. The round stem and leaves are glaucous, and the small, pendulous, bell-shaped, yellow flowers are borne in graceful umbels. Shown by Mr. Amos Perry.

Campanula carpatica var. Chewton Joy.—A dwarf, compact variety which bears plenty of relatively large, widely-open, pale blue flowers which have silvery-white centres. Shown by Messrs. M. Prichard and Sons.

Gentiana Lagodechiana, Hanscombe variety.—A more vigorous variety of the Caucasian Gentian which is recommended for the rock garden. The flowers are large and dark blue, freely speckled and marked with white.

Gentiana Lagodechiana × *G. septemfida var. cordifolia*—The award to this desirable rock garden plant is given subject to its being named. In general appearance it is a much more robust and greatly improved G. septemfida. It produces larger, much more floriferous heads of brighter blue flowers which are less speckled. This, and the foregoing, was shown by C. T. Musgrave, Esq., Hascombe Place, Godalming.

Pentstemon Eatonii.—This admirable species was introduced from California in 1883. The lower leaves are broadly acuminate and of rich shining green colour. The rich crimson-scarlet flowers are borne in a long, graceful panicle. Shown by Mr. T. Hay, Hyde Park, London.

Tillandsia splendens var. major.—This handsome Bromeliad was shown as a Vriesia, but the plant appears identical with the figure in *Bot. Mag.*, t. 4,382, of Vriesia speciosa. a name which has since been changed to Tillandsia splendens. A very robust specimen of this stove Bromeliad was shown. The long, green leaves were marked with very dark chocolate and the central scape of vivid scarlet bracts was nearly two feet long. The small, solitary flowers were whitish. Shown by Messrs. Sander.

For Trial at Wisley.

Eschscholzia Double Carmine Queen.—A semi-double variety of rosy-carmine colour.

Eschscholzia Flambeau.—An uncommon and showy variety. The semi-double flowers are prettily crimped and are of fiery orange-scarlet colour, shot with gold. Both varieties were shown by D. W. Gardiner, Esq., Thornington, Colchester.

Hemerocallis hybrida var. George Yeld.—An uncommon Day Lily. The large flowers are of clear yellow colour in the centre, and brownish towards the margins. Shown by Mr. Amos Perry.

Phlox Mrs. Symons-Jeune.—A handsome spike of large, blush-pink flowers which have small, carmine centres.

Phlox Magna Charta.—This is a brighter counterpart of the foregoing. Both varieties were shown by Captain Symons-Jeune.

Groups.

At the far end of the hall a splendid group of herbaceous Phloxes was displayed by Messrs. H. J. Jones, Ltd. The principal varieties were Leo Schlageter, deep rose-pink; Daily Sketch, pink with carmine centre; C. Edwards, salmon-pink; Attraction, purple; Evelyn, pink; Antoine Merci, lilac and white; and Mia Ruys, white. Mr. S. J. Goodliffe had a smaller collection of herbaceous Phloxes which included Embrassement, salmon-rose; Widar, lilac with a white centre; Thor, salmon-pink; Homeland, scarlet; and Frau Antonin Buchner, white.

An interesting collection of seedling herbaceous Phloxes was grouped by Captain Symons-Jeune. These bore spreading heads of large flowers. The named sorts included Mrs. Cecil Hanbury, vivid rose, and Runnymede, purple. Several good Phloxes were associated with Gaillardia The King and other flowers by Messrs. Rich and Cooling. The Suffolk Seed Stores also showed Phloxes, and grouped them with Gladioli, Heucheras, Monardas and Gaillardias. Mr. A. Miles and the Misses Hopkins had small collections of seasonable border flowers.

Romneya Coulteri, Sidalceas and herbaceous Phloxes were displayed by Messrs. G. and A. Clark. Many spikes of the graceful Poterium tenuifolium var. album, various Lythrums, Eryngiums and a good selection of dwarf Campanulas were grouped by Messrs. M. Prichard and Sons, while Mr. Amos Perry showed Monarda didyma var. Cambridge Scarlet, Asclepias tuberosa, Lilium Wallichianum superbum, Delphinium sulphureum and several pans of the pretty little Nymphaea pygmaea Helveola.

Sidalceas were shown in quantity by several exhibitors. Messrs. Stark and Son, Ltd., included such good varieties as Graceful, rose-pink; Lilac Queen, rosy lilac; Attraction, old rose; and Silver Spray, pale silvery-pink. Mr. H. Hemsley included Marcus Adams, F. W. Alesworth, and Mrs. L. R. Russell in his collection.

An admirable group of hardy annuals was contributed by Messrs. Sutton and Sons. In the centre there was a large vase of the glowing flowers of Venidium fastuosum; Arctotis grandis and mixed Arctotis, Dimorphotheca aurantiaca were also well shown. There were many colour varieties of the valuable annual Larkspur, of which a large vase of mixed shades of colour was particularly effective. Other annuals which were included were Sweet Sultans, blue Swan River Daisies, Giant Candytuft, Nigellas, Eschscholzias and several wholly admirable varieties of double-flowered Godetias. Messrs. Daniels Bros., Ltd., had a good exhibit of annual Larkspurs in distinct colours. The chief were Carmine, Pale Blue, Dark Blue and Exquisite, salmon-pink.

Gladioli in quantity were staged by Messrs. Kelway and Son. The large-flowered sorts predominated and included Palestine, pink, with large, vivid blotches; Pinkie, yellow, with carmine blotches; Countess of Leicester, bright rose; James William Kelway, glowing crimson, and Earl Compton, blush with yellow blotches. On the opposite side of the hall, Mr. H. Prins showed Gladioli. His primulinus varieties included Yellow Favourite, Souvenir, George Arends, Lilac Wonder, Scarlet Cardinal and Phenomenal.

Roses were shown in considerable beauty by Messrs. B. R. Cant and Sons, Mr. J. H. Pemberton, and Messrs. D. Prior and Son. Messrs. C. Engelmann, Ltd., and Messrs. Allwood Bros. had their customary collections of fresh and fragrant Carnations of good quality.

In the centre of the hall Messrs. L. R. Russell, Ltd., had an uncommon exhibit in the form of a moss-covered trellis supporting Nepenthes, above a pool of tropical Nymphaeas, with attendant smaller pools of hardy Nymphaeas. The Nepenthes included N. Hookeriana, N. formosa, N. Russelli and N. Sir William Thistleton-Dyer.

Fruit and Vegetable Committee.

Present: Mr. E. A. Bunyard (in the chair), Mr. George Kelf, Mr. J. Cheal, Mr. H. Markham, Mr. A. Bullock, Mr. W. F. Giles, Mr. A. W. Metcalfe, Mr. A. Poupart, Mr. J. C. Allgrove, Mr. E. Beckett, Mr. H. V. Taylor, Mr. W. H. Divers, Mr. C. G. A. Nix and Mr. A. N. Rawes, Secretary.

Groups.

It is many years since such a grand exhibit of fruit trees in pots, as was shown on this occasion by Samuel Wallrock, Esq. (gr. Mr. W. H. Holloway), The Manor House, Stanmore, Middlesex, has been staged at a meeting of the Royal Horticultural Society, and we heartily congratulate Mr. Wallrock and his gardener upon the excellence of the exhibit, and upon the high cultivation evidenced in the healthy and well-cropped specimens displayed. The group contained a wide variety of fruits and was well arranged, with large trees of Peaches and Nectarines, Apples, Pears and Plums filling the centre, and lined with single, double and triple, heavily-fruited cordons of Gooseberries in variety, and Red and White Currants, with half-a-dozen splendid Grape vines of Black Hamburgh and Foster's Seedling. Naturally, the Plums, Apples and Pears had not reached ripeness, but they were all carrying good crops and extremely healthy foliage. Of Apples, there were large trees of Lady Sudeley, James Grieve, Cox's Orange Pippin, Peasgood's Nonsuch, St. Everard, Langley Pippin, Worcester Pearmain and Charles Ross; Pears were represented by Marguerite Marillat, Williams's Bon Chrêtien, Triomphe de Vienne and Dr. Jules Guyot, and Plums by Jefferson's, Kirke's and Early Transparent Gage. Among Gooseberries, which were carrying heavy and fully ripe crops, were Broom Girl, May Duke, Pilot, Golden Gem, Whinham's Industry, Lancashire Lad, Shiner and Warrington. There were grand bushes of Red Currants Raby Castle, Comet and Warner's Grape, and White Currant Versailles. Peaches were represented by Peregrine and Early Alexander, and Nectarines by Pineapple and Early Rivers, so that variety was not lacking in this praiseworthy display, which well deserved the Gold Medal awarded to it.

Messrs. Stark and Son showed dishes and sprays of ripe fruits of Tomato Dainty Table. The red fruits are of medium size and very regular in shape in the bunch.

WATFORD AND HOME COUNTIES.

The third Annual Summer Show of this Society, held in Cassiobury Park, Watford, on July 23 and 24, was a very extensive affair, for beside the horticultural section, which comprised over 200 classes, together with numerous trade exhibits, there were competitions for honey, a horse gymkhana, and numerous other events which added general interest to the show. The majority of the horticultural classes were well filled—they were housed in seven marquees—and competition in all the sections was keen, while the trade exhibits scattered throughout the tents contributed largely to the bright effect.

In the trade section, Messrs. Chaplin Bros., Ltd., were first for a display of cut Roses, eighteen distinct varieties, their best blooms being of Mrs. C. Lamplough, Lady Inchiquin, Los Angeles and George Dickson; Messrs. F. A. Wheeler and Son secured the second prize, showing Los Angeles, Charles P. Kilham and Clarice Goodacre in good condition.

The Watford Horticultural Society's Silver Cup, for the best trade group on a space of 200 square feet was awarded to Messrs. T. Rivers and Son, who put up one of their well-known exhibits of fruit trees in pots. Messrs. E. W. King and Co. were second in this interesting class, showing a splendid collection of Sweet Peas, while the third prize went to Messrs. A. Scrivener and Son.

In Division B, open, trade excluded, the most attractive class was that for a group of flowering and foliage plants, on a space not exceeding 200 square feet. There were several attractive exhibits, the Cup presented by Messrs. Lane's Nurseries, Ltd., being awarded to J. Pierpont Morgan, Esq. (gr. Mr. G. F. A. Steward), West Hall, Watford, whose charming group contained well-grown Begonias, Caladiums, Codiaeums, Liliums and other subjects; it is also of interest to note that this exhibitor put up a very fine non-competitive exhibit of fruit trees in pots. Miss Wallis (gr. Mr. S. Holland), Highfield, Watford, was second in this class, with a triangular bed of well-grown plants in variety, while the third prize was awarded to the Mental Hospital, Napsbury, for a group in which well-flowered specimens of Campanula pyramidalis figured prominently.

In the classes for Roses, the best six vases came from the Mental Hospital, Napsbury; Mrs. S. G. Barratt, King's Langley, was first for three vases, and for twelve vases in at least four varieties; Mrs. E. Carpenter, King's Langley, was first in the popular class for a decorative basket of Roses, and Mr. A. L. F. Cook, Hayes, Middlesex, led for a single decorative vase.

The two classes for Sweet Peas added considerably to the attractiveness of the tents in which they were staged, the successful exhibitor being S. Wallrock, Esq. (gr. Mr. W. H. Holloway), The Manor House, Stanmore, who was first in both classes, for eighteen vases, securing the Earl of Clarendon Challenge Cup, and for six vases.

The majority of the special classes for annuals, various herbaceous and bedding plants, Carnations, foliage plants in pots, etc., were well filled, and competition in general was keen.

The numerous classes for fruits and vegetables in this section also provided some very interesting exhibits and close competition.

In the vegetable classes, S. Wallrock, Esq., was the leading prize-winner, other successful exhibitors being Major C. B. Krabbe, Calcot Grange, Reading; Lt.-Col. Sir W. Halsey, and J. P. Morgan, Esq.

Major-Gen. Caley, Swindon, showed the best set of five Nectarines, one variety, and J. W. Batty, Esq., was first in a similar class for Peaches. The best two bunches of black Grapes were shown by Major-Gen. Caley; J. P. Morgan, Esq., was first for white Grapes, while S. Wallrock, Esq., led for two Melons.

As usual, the class for a decorated dinner table was extremely popular, the prize-winning decoration being arranged by Mr. F. J. Jones, Watford, who used orange-coloured Sweet Peas very effectively; second, Mrs. F. A. Parks, Watford.

As in the previous section, there were innumerable exhibitors in the division for amateurs employing not more than two gardeners, many of the classes, both for flowers and vegetables being well filled.

The G. R. Scrivener Cup, for a group of flowering and, or, foliage plants, on a space not exceeding 100 square feet, was deservedly awarded to Alderman T. R. Clark, for a very meritorious mixed group; Mrs. H. E. Dunhill, Harpenden, was first for three vases of rambler Roses; six vases of Sweet Peas; and for six vases of annuals; other first prize winners in the floral classes were Mr. A. L. F. Cook, Mr. R. H. Long, Watford, and Mr. W. E. Fowler, Watford. In the fruit and vegetable classes in this section the leading prize-winners were Mr. R. H. Long, Watford; Mr. P. Henley, Watford; Mrs. Keevil, Chorleywood; and Mr. R. Boulton, Watford.

The same high standard displayed in the foregoing classes was displayed in the very numerous classes in the section for amateurs and gardeners in the Home Counties, and allotment holders and cottagers, especially in the single dish classes for vegetables, and the judges to whom these classes were allocated must have had an extremely difficult, and certainly a very protracted, task in judging them.

Non-competitive exhibits from trade growers were fairly numerous. Messrs. R. and G. Cuthbert showed Gladioli in variety; Mr. S. J. Goodliffe had a collection of herbaceous plants—Phloxes in variety, Delphiniums, Scabiosa caucasica, etc.; and Messrs. Rambotham and Co. staged a small collection of Roses.

Messrs. John Peed and Son were responsible for a very attractive group of indoor plants, which embraced Gloxinias in many fine varieties; Streptocarpus, Liliums, Hydrangeas, Caladiums, Codiaeums, and other popular subjects, charmingly arranged. Numerous good varieties of Scabiosa caucasica, together with Gaillardias, Coreopsis, Alströmeria aurantiaca and Romneya hybrida, were staged by Messrs. Isaac House and Son, while Messrs. W. Cutbush and Son, Ltd., showed topiary specimens in conjunction with herbaceous plants in variety and dwarf Polyantha Roses.

A collection of specimen blooms of their famous Begonias, together with Phloxes in variety, and Lupins, was staged by Messrs. Blackmore and Langdon, while herbaceous plants were shown by Mr. W. A. Collier. A good collection of fruit trees in pots was exhibited by Messrs. Lanes, Ltd.

Roses were shown by Messrs. Laxton Bros., and also by Messrs. B. R. Cant and Sons, Ltd., while a very interesting exhibit of Water Lilies in a long, shallow tray, with a background of semi-aquatic plants, Bamboos and Ferns, was arranged by Messrs. L. R. Russell, Ltd., who also showed dwarf Fuchsias, flowering Clematises in pots, and a few alpine plants. Messrs. Daniels Bros. showed Gladioli, Roses, Larkspurs and Sweet Peas, which made a very bright display; and Messrs. H. Simmonds and Sons staged herbaceous plants and annuals, including some very fine Sweet Peas.

GUILDFORD AND DISTRICT ROSE.

The third annual Rose Show of the above Society, which was to have been held on June 26, but had to be postponed owing to the extreme lateness of the Rose season, was held on July 10, and marked another big stride in the progress of this young Society, whose membership covers a wide area in Surrey, Sussex and Hampshire. Entries this year totalled 403, as against 320 last year, and the attendance of over 4,000 people showed an increase of about 1,000.

Messrs. Chaplin Bros., Ltd., secured the premier award in the big group class, being closely followed by Messrs. B. R. Cant and Sons, and Messrs. Frank Cant and Co., Ltd. Mr. J. H. Pemberton secured a Gold Diploma in the same class.

For a group ten feet long, the Dowty's Rosery, Mr. George Lilley and Mr. Henry Street were placed first, second and third, in the order named. Entries in the class for twenty-four blooms and in the class for eighteen bunches were numerous, the Cup for the latter class, which is a new one, being secured by

Messrs. Warner, with a very fine display, closely followed by Mr. F. Spooner and Messrs. Lund Bros., second and third, respectively.

The twenty-six classes for amateurs were so well filled that it has already been decided to increase their number next year: one class had fifty entrants, forty-seven of whom staged their exhibits. The outstanding classes were those for decorative bowls. There were four classes with entries varying from eighteen to twenty-six in each, and all of a high standard.

The open amateur class for eighteen blooms provided keen competition, Mr. Cuthbert Dixon, High Wycombe, being placed first, Mr. Vivian Rolt, Pulborough, second, and Sergt.-Major Stent, Guildford, third. Decorative Roses in stands and baskets were a very prominent feature of the show and well illustrated the modern tendency to provide an alternative to the stiff setting of the exhibition box.

Considerable interest was aroused by an exhibit of the first Roses cut from the new Guildford Municipal Rose Garden, the formation of which, with the permission of the Corporation, was taken over by the Guildford and District Rose Society in the spring of this year. The blooms were from the first 150 trees, which were planted on Good Friday last.

Mr. A. R. Darlington, the veteran Rose authority and immediate Past President of the National Rose Society, speaking at the luncheon, stated that he had visited a large number of Rose shows over a number of years, and that this was the best provincial show he had ever attended. Also, that he had never seen a larger number or better entries in the novices' classes by those who would ultimately become the standby of the Society.

READING GARDENERS'.

By the kind permission of Lionel de Rothschild, Esq., the Annual Outing of the Association was held in the delightful gardens and grounds of Exbury House, on July 10. The party, numbering between eighty and ninety, went by motor-coach via Romsey to Lyndhurst, where luncheon was provided at the Stag Hotel, after which the party proceeded to Exbury and spent the afternoon inspecting the beautiful gardens. The vast woodland garden was quite a revelation, and although the Rhododendrons were nearly over, there were two or three magnificent specimens of R. discolor still in flower. In the centre of these gardens are two large Lily lakes in which Nymphaeas of the finest varieties were flowering luxuriantly, the colours ranging from white to deep red, especially noticeable being Escarboucle (bright vermilion), Gladstoniana (snowy-white), and James Brydon (rosy-crimson). A walk through the vegetable quarters, which are very extensive, brought the party to the greenhouses, which were filled with Cherries in pots, Plums in pots, Figs, Peaches, Grapes, Orchids, Carnations, Anthuriums, Clivias and seedling and tender Rhododendrons. Especially interesting were the blue Water Lilies in tanks, including the variety Kew Special.

Returning to Lyndhurst, tea was partaken of, and after a pleasant drive via Southampton and Winchester, Reading was reached at 9.30 p.m.

SALISBURY GARDENERS'.

On July 15, nearly seventy members of the Salisbury and District Gardeners' Society, with their Vice-President, Mr. A. C. Jonas, Chairman, Mr. S. W. Tucker, and Hon. Secretary Mr. W. F. Gullick, attended the annual excursion. The weather was ideal. The party, travelling by char-a-bancs, first paid an early visit to Heale House, the residence of their President, the Hon. Louis Greville, where a very pleasant hour was spent, viewing the charming Japanese garden, and a new Rose garden, which, considering that it was only laid out and planted last autumn, was looking remarkably fine.

Passing through the delightful village of Woodford, where some of the finest Oaks of the district are to be seen, the party proceeded to Marlborough for lunch, and then on to Littlecote, Hungerford, the seat of Sir Ernest Salter Wills, Bart. Here, under the guidance of Mr. W. J. Smith, the gardener, a tour of the gardens was made. The magnificent herbaceous borders were fine colour schemes in yellow, gold and blue. There is no formality about the gardens at Littlecote and the winding stream adds to its beauty. The kitchen garden bore the same high level of quality as the pleasure grounds. The fine bowling green, laid down in the reign of Queen Elizabeth, occasioned a good deal of interest, as did also the old Tudor mansion which, standing amid such beautiful surroundings, created a charming picture.

Tea having been partaken of, the homeward journey was made via Andover, where, during the cool of a beautiful evening, the gardens of Amport House, the residence of Colonel and Mrs. Sofer Whitburn, were visited. Here, under the guidance of the gardener, Mr. A. S. Gooden, a pleasing, but more formal style of lay-out was seen. The gardens and park, viewed from the main terrace, with its magnificent stone balustrade, provided a delightful picture; miniature streams, flowing into a small ornamental pond, and in the distance some of the finest Silver Limes in England, planted by a former Marquis of Winchester, about seventy years ago were delightful.

During the day, Mr. Jonas expressed the thanks of the visitors to the respective owners of the gardens viewed, and on arrival at Salisbury, a hearty vote of thanks was accorded the Hon. Secretary, Mr. W. G. Gullick, for the trouble he had taken in arranging such a delightful and educational trip.

BIRMINGHAM AND MIDLAND COUNTIES GARDENERS'.

The close of the summer 1929 programme of visits in connection with the above Association took place on July 27, when a party of 168 members, ladies and friends, visited Windsor by special 7.45 a.m. train from Snow Hill, and arrived at Windsor at 10.45 a.m. The party was met at the station by Mr. C. H. Cook, gardener to H.M. The King, who arranged a most interesting programme. By special permission obtained from H.M. Privy Purse Department, the State Apartments, Albert Memorial and St. George's Chapel Royal were visited before luncheon, while visits to the Royal Mews, east terrace garden front, and the extensive ornamental grounds of the Royal gardens, Frogmore, occupied the whole of the afternoon. Luncheon was served at the Castle Hotel, to which Mr. and Mrs. Cook and Mr. and Mrs. Hubbard (pleasure ground foreman) and visitors, including press representatives, were invited. Mr. J. Smith, Chairman of the Association, and chief Superintendent of the Birmingham City Parks and Cemeteries, submitted the loyal toasts. "The Association" was proposed by Mr. C. J. L. Ray, who congratulated the association on its excellent work. After tea, hearty thanks were accorded Mr. Cook for his kindness in conducting the party, to which he suitably responded.

The party left Windsor at 7.40 p.m., arriving at Birmingham at 10.30 p.m., when all agreed that this was the most successful gathering during an experience of fifty years.

SAFFRON WALDEN HORTICULTURAL.

While most districts have suffered severely from drought, Saffron Walden has been particularly fortunate in having had several thunderstorms during the past month, and the rainfall, although at times heavy, has been of greatest benefit to the gardens and nurseries in the immediate locality. This was evidenced by the all-round excellence in the quality of the exhibits at the Saffron Walden Horticultural Society's show, held in Lord Braybrooke's park at Audley End, on July 25. Since the show was resuscitated after the war, it has advanced year by year until it has once again become one of the finest horticultural exhibitions in the eastern counties.

There were, this year, well over a thousand exhibits in the competitive classes, and the competition was so keen in many of them that the judges had no easy task in making their awards.

Mr. W. H. Scott, a local amateur, won no fewer than eighteen prizes, his collections of herbaceous flowers, annuals, and Gladioli being exceptionally good.

Mr. Engelmann's Challenge Cup for cottagers and allotment holders gaining the largest number of prizes, was secured for the third year in succession by Mr. J. Linsdell, and was thus won outright.

Mrs. Barker, Saffron Walden, once again had the honour of winning the much coveted Babington Smith Championship Silver Bowl, for a table decoration. There were fourteen decorated tables, which occupied the whole of the centre of one large marquee, while the sides were filled with choice exhibits of Roses, Sweet Peas, baskets and vases of flowers, ladies' sprays, etc.

The trade exhibits were again quite a feature of the show. Messrs. C. Engelmann, Ltd., occupied the whole of a large marquee with a magnificent display of Carnations, arranged very effectively, and Messrs. R. Bolton and Son staged a superb collection of Sweet Peas. Messrs. J. Vert and Sons, Ltd., of Saffron Walden, filled a large space with pot fruit trees laden with fruits; Messrs. Morse Bros., and Mr. J. Wright, of Takeley, exhibited grand collections of Roses; and Mr. S. J. Goodliffe showed herbaceous flowers in variety.

CARDIFF GARDENERS'.

The Society's third Saturday outing was held on July 20, when visits were paid to Llanilterne and Craig-y-Parc. The party left Cardiff by omnibuses, proceeded to Bnyawel Fruit Gardens and were met by Mr. J. Basham, who conducted the members over his plantations, where they were very much interested in the large variety of fruits grown by Mr. Basham in this part of south Wales. After exploring these extensive gardens, the members were entertained to tea in the Village Hall by Mr. Basham and members of his family, who were heartily thanked for their kindness and hospitality.

A visit was then paid to Craig-y-Parc, and a very hearty welcome was extended on arrival by the owner, Thomas Evans, Esq., C.B.E., and Mrs. Evans, who, with the assistance of Mr. Macgregor, their gardener, conducted the party over the extensive and beautiful grounds. The gardens have been recently laid out in old-English and Italian styles. Being on top of a hill, there are many charming terraces and walks, and at every corner were interesting surprises. The flowering shrubs were a feature and led out into natural woodland.

The annual outing will take place on August 12, when a visit will be paid to Testworth Park, Gloucestershire.

TRADE NOTES.

An interesting example of the practical application of electric heating occurs in the north of England, where a keen amateur grower of Orchids, with large greenhouses for these and other tropical plants, has hitherto had to depend upon hot-water pipes connected to a coke-fired boiler for the maintenance of a uniform temperature. Firing late at night, again early in the morning, as well as several times during the day, proved tiresome, especially as in the other houses containing semi-tropical plants a lower temperature was sufficient. The obvious remedy, therefore, was to instal separate heating for the Orchid houses and make them independent of the remainder of the buildings. For this purpose the Industrial Heating Department of the General Electricity Co., Ltd., was consulted, and a special, heavy, water-proof type of tubular heater was designed. A number of these heaters was experimentally installed in the Orchid houses to a total length of eighty-two feet, with a loading of sixteen kw., and connected directly to the three-phase network. To preserve the proper saturation of the atmosphere, the heaters themselves are constantly covered with water, which speaks well for their design, and accurate temperature control in the Orchid houses is effected by means of an adjustable air thermostat working in conjunction with a three-pole 25 amp. Witton Ironclad Contactor. With the advantage of a special tariff of ½d. per unit arranged with the local supply company, the Orchid grower is now congratulating himself on the general convenience and more economic advantages of these G.E.C. electric tubular heaters, as compared with the old-fashioned system of heating they have superseded.

There will be many regrets expressed regarding the news that Messrs. J. R. Pearson and Sons, Ltd., Lowdham, are giving up their business as nurserymen and fruit-growers. The firm has been established for about a century and has always enjoyed a high and well-merited reputation for its goods. In our experience, few nurseries are so admirably arranged or so well kept as those at Lowdham. Fortunately, however, the firm will not cease its activities by the disposal of the nurseries, as it will continue business of seedsmen and bulb merchants.

ANSWERS TO CORRESPONDENTS.

Correction.—We regret that an error occurred in our report of the meeting of the Royal Caledonian Horticultural Society, which appeared in our issue of July 27. It was the Edinburgh City Parks Department to which a Cultural Certificate was awarded for a group of Hydrangeas, etc., and the Roses were exhibited by Messrs. Dicksons and Co., not by Messrs. Alex. Dickson and Sons.

Chrysanthemums.—*H. J. G.* Assuming the Chrysanthemums you recently purchased were potted into nine-inch or ten-inch pots, and were restricted to three growths—which is generally the number of shoots taken up to produce large blooms—all the varieties listed are best taken on what is termed the crown bud, *i.e.*, when a bud appears on each of the three shoots, secure it by removing all side-shoots or buds, leaving only the central one; when this is secured, the roots should be fed with liquid manure or, better still, with some approved fertiliser recommended for the Chrysanthemum, using it twice weekly until the blooms are nearly developed, when it should be discontinued. Weak soot-water is also very beneficial and will tend to produce dark green foliage. The plants should be grown outside until about the third week in September, when they may be stood in a cool, airy house where only sufficient warmth should be allowed in the hot-water pipes to dispel night moisture. The varieties named in your letter are best suited for large blooms, and if treated as advised should be ready for cutting about the first or second week in November. Mrs. F. W. Wallis, yellow; Edith Cavell, chestnut-bronze; Louisa Pockett, pure white; Miss V. Chichester, silvery-mauve; Mrs. H. E. Jones, bronze-red; Mrs. G. Drabble, white, very fine (Japanese incurved); J. H. Silsbury, creamy white; Mrs. R. H. Pulling, lemon-yellow; and Pockett's Crimson, crimson, are all Japanese varieties. The above are not recommended for the production of small flowers for cutting, there being others that would give better returns for this purpose, especially among decorative sorts.

Culinary Peas Diseased.—*S. W. M.* The Peas are affected with foot-rot, which is due to the fungus Thielavia basicola. This disease is prevalent on plants growing in waterlogged soils. Attention should be paid to drainage before another crop is sown on the land. The application of sulphate of potash to the infected rows will induce resistance in the plants.

Garden in Meadow Land.—*J. H. H.* You have guessed well that most or all bacterial life has gone out of the trenched meadow land. That cannot be considered as due to the fact that the land has lain in pasture for thirty years; but that the turf was buried and the dead, inert soil brought to the top. Farmers often take two crops of Corn in successive years from meadow land, by simply turning over the turf by ploughing. We have seen the turf simply pared off and laid on the top after trenching. In another case a deeper sod was turned over with a spade, grass side down, and good crops of several kinds of vegetables taken from it the first year, including Beet, Parsnips and Carrots. Next autumn you should start digging the ground deeply enough to bring the turf to the top. Your difficulty is increased by the dry season, but the soil will be more mellow in autumn, and will be greatly improved by frost, air, and rain. The red sandstone soil of your district is a good one, and soon improves by cultivation. Keep it clear of weeds at all times and the wireworms will disappear if you continue applying vaporite and kill all you see while digging.

Gardener's Notice Without an Agreement.—*E. L.* In the absence of any agreement or local custom to the contrary, you are entitled to one month's notice, or one month's wages in lieu of notice, you being in law a domestic servant.

Lease of Garden.—*J. H.* If your lease expires by effluxion of time in May, 1930, there is no need for the landlord to give you any notice. You are not entitled to protection under the Rent and Mortgage Interest (Restrictions) Acts, as these would not apply to your tenancy. It is not possible to answer fully the other questions raised in your letter without seeing the lease and having more precise information as to the exact facts. Much depends on whether the property was let as a nursery ground or market garden.

Name of Fungus.—*C. W. R.* The fungus sent appears to be Psalliota elvensis, a Mushroom, and stated to be edible.

Names of Plants.—*W. D.* 1, Dianthus, one of the numerous garden varieties; 2, Dianthus, too scrappy for identification; 3, Dianthus caesius (form); 4, Saponaria caespitosa; 5, Veronica filifolia.—*E. B.* Prunus lusitanica var. myrtifolia—Portugal Laurel.—*W. and S.* Onotrychis sativa.—*H. S. B.* 1, Geranium pratense; 2, G. ibericum; 3, Cephalaria alpina; 4, Tradescantia virginiana; 5, Oxalis floribunda; 6, Scilla peruviana.—*C. J. L.* 1, Polygonum affine; 2, Phlomis fruticosa; 3, Astrantia major; 4, Thymus Serpyllum; 5, Anthericum Liliago; 6, Potentilla argyrophylla var. (there are many garden varieties of this plant); 7, Inula glandulosa; 8, Allium Moly; 9, Iris sibirica; 10, Nepeta ucranica; 11, Hieracium aurantiacum.—*C. C. C.* Ptelia trifoliata.—*S. A.* We cannot undertake to name florists' flowers.—*J. H. G.* 1, Tradescantia virginiana, purple-flowered; 2, a variety of tuberous-rooted Begonia.—*Miss H.* Spiraea Van Houttei.—*P. D.* Polygonum baldschuanicum.—*E. H. B.* 1, Pyracantha Rogersiana; 2, Cistus cyprius; 3, Crataegus Carrierei; 4, Phlomis fruticosa.—*J. C.* Tropaeolum polyphylum.—*F. E. S.* 1, Spiraea filipendula; 2, Campanula lactiflora; 3, not recognised; 4, Philadelphus microphyllus; 5, Stachys lanata; 6, Hemerocallis fulva.—*A. L. C.* We cannot undertake to name Rose varieties, we suggest you take them to a local Rose nursery.—*G. H. M.* Probably Jasione montana; please send complete specimen.—C. V. Leucadendron argenteum.—*Barbery.* 1, Salvia nemorosa (this is supposed to be a S. virgata hybrid); 2, Pelargonium atrum (a South African species).—*M. C.* Oenothera fruticosa.—*A. W.* Jasminum sp., probably J. Beesianum, but the specimen was shrivelled and there was only one remnant of a flower.

On Growing Chrysanthemums, Vanilla, Leucadendron, etc.—*R. F. S.* (1) Without knowing all the circumstances and conditions, it is not possible for us to state why your Chrysanthemums do not grow and flower properly. The condition mentioned, however, suggests lack of plant food in some form; if such is the case, the use of a suitable manure should overcome the trouble. (2) In the flowers of Vanilla the organs are so arranged that self-pollenation is impossible. Naturally, pollenation is stated to be effected by some insect; at the top of the column is a hood which covers the pollen masses, and below this is the viscid stigmatic surface, protected and hidden by a projecting lip called the lamellum. The pollen is shut in by the hood, and the stigma by the lamellum, so that two obstacles prevent self-pollenation. In artificial pollenation the object is to remove these obstacles, and to permit the pollen masses to approach the stigma. This is effected, firstly, by detaching the hood, which can be done by touching it with a piece of sharpened wood, and, secondly, by slipping the lamellum under the anther, when the pollen masses and stigma may be easily brought in contact by gentle pressure between the thumb and finger, or the pollen masses may be transferred from one flower to another. (3) Good seeds of Leucadendron argenteum, in our experience, usually germinate quite readily. We usually file through, or with a knife, pare through, a small portion of the hard outer coating; over-watering should be guarded against until the seeds germinate.

Rose Ophelia Failing to Open.—*W. W.* and *P. W. B.* Your Roses would appear to be scorched by water lodging in the buds. Judging by the state of the growths they would appear to have been over-watered.

Rose Unhealthy; Treatment of Gladioli.—*N. G.* The specimen of Rose was too meagre to make a satisfactory diagnosis of the trouble. The leaves have been attacked by the larvae of a sawfly, Eriocampa rosae. There is no fungus present on the foliage, but the plants appear to be suffering from drought conditions. Gladioli at this period of growth should not require very much manure as the flowers are already formed. The corms would benefit after flowering by the application of some Peruvian guano, using about one ounce to one gallon of water, but the dosage should not be overdone.

Tulip Bulbs with "Fire"—*A. R.* The Tulip bulbs were affected by "Fire," due to Botrytis tulipae. Several answers have been given to the same query recently (see p. 454, Vol. LXXXV.)—It was impossible to identify the plants from the material sent; the flowers should accompany the shoots. The stem is that of one of the Sumachs, Rhus species, while the leaf appears to be that of a shrubby Spiraea.

Valuation of Garden Produce, etc.—*Anxious.*—The matter depends so much upon the terms of your tenancy and local custom that it is impossible to express an opinion, without full information. You should consult a local valuer.

Vines Unhealthy.—*G. C.* The vine foliage is free from attack by any pathogenic organism. The trouble has arisen from draughts and sudden changes in temperature. Some of the leaves show signs of "scorch," so that the glass should be shaded during bright, sunny weather.

Woodlice in Melon and Cucumber Houses.—*B. J. H.* Ask your seedsman or horticultural sundriesman to get some of Corry's "Woodlice and Ant Death" for you. It kills woodlice and many other kinds of vermin in half-a-minute, while it is non-poisonous and may be used in any place infested with vermin. Ask for instructions with it, although these are usually given on the package or bottle, as the case may be. Woodlice go into houses for the sake of warmth, and if they find food as well, they stay.

Zinnias, per doz. blooms ...	1 6—4 6

REMARKS.—A certain amount of depression continues throughout this department, and prices in general do not show any improvement, owing to lack of demand, which is not unusual for July. Carnations, Roses and Liliums may become somewhat more valuable this week-end, owing to August Bank Holiday. Asters and Chrysanthemums show a slight increase, but there is little demand for the latter. All Statices are arriving in fine condition, including S. latifolia and S. incana. Some very fine Zinnias are on offer in various colours, at from 1s. 6d. to 6s. per dozen blooms; also a few blooms of Gerberas at 4s. to 5s. per dozen blooms. The supply of choice foliage, such as Asparagus plumosus, A. Sprengeri, Maidenhair Fern, and of all hardy foliage, is too heavy for present requirements.

REMARKS.—Brisk conditions in practically all sections of the market are ruling at the moment, conditions which were naturally assisted by the continued fine weather. Increased quantities of hothouse Grapes from Holland and Belgium have brought about lower quotations for English Grapes; Peaches and Nectarines are still selling well, and Melons, if good, realise comparatively high prices, although with the London season drawing to a close, there is an easier tendency generally for choice fruits. It must be many years since English Cherries have been marketed in such good condition, and all varieties have been, and are still, selling remarkably well. Black Currants, however, are a weak market, probably owing to the fact that they are rarely consumed as dessert, and cooking during the very hot weather is not a popular pastime, in addition to which quantities have been very heavy. There has been a good enquiry for dessert Gooseberries, Leveller variety, but not much demand for other sorts, and prices are on the low side. Raspberries are selling well. There is a fair sprinkling of English Apples available, but for the most part they consist of thinnings: Early Victorias and Grenadiers, of medium size, have sold well. Mushrooms are an improved trade, mainly because supplies are not so heavy. In the Tomato section the competition of Dutch Tomatos has been felt acutely, and prices all round are too low to bring much satisfaction to the growers. Cucumbers are selling well if in good condition, but fruits lacking colour are difficult to dispose of. Peas and Beans, in common with most other vegetables, are not selling freely, and even salads are not going out quite so fast as a few days ago. Plums from Italy are in good demand, as are Pears from the same source. There are still Apples available from Australasia, but the recent arrivals have been out of condition. Oranges and Lemons have been in keen demand and continue to sell well. Potatos are not a particularly good trade, supplies being heavier, and prices are slightly lower.

GLASGOW.

A good business was done in cut flowers last week, at prices which favoured buyers. Carnations continued plentiful and cheap at 6d. to 1s. 6d. per dozen; Gladioli ranged from 1s. to 3s.; Roses, 1s. to 2s. 6d.; Lilium longiflorum, 2s. 6d. per bunch; Sweet Peas, 1d. to 6d.; Stocks, 2d. to 5d.; Pyrethrums, 3d. to 4d.; Scabious, 3d. to 5d.; Sweet Williams, 2d. to 3d.; Calendula, 1d. to 4d.; Statice, 6d. to 1s.; white Heather, 6d. to 9d.; Marguerites, 1½d.; and Gypsophila, 1d. to 3d.

A large business was done in home-grown fruits at reduced values. The market was overstocked daily with Black Currants, which sold at 4d. to 5d. per lb.; while Red Currants declined to 3d. Raspberry prices ranged from 6d. to 9d.; Gooseberries, 2d. to 3d.; Cherries, 13s. per sieve; Gages, 15s.; home-grown Melons, 6s. each; Peaches, 7d. to 1s. 2d.; and green Apples, 3d. to 4d. per lb. Imported fruits were quoted as follows:—Italian Plums, 5s. 6d. per tray; Melons, 12s. 6d. (24's); Canteloupes, 1s. 6d. each; Pineapples, 4s. 3d.; Grape Fruits, 31s. per case; Californian Oranges, 22s. to 25s. per case; New Zealand Apples, 20s. to 23s.

Tomato supplies exceeded the demand, and on Friday Grade A fruits were sold at from 2d. to 4d. per lb. Cauliflowers realised 4s. to 5s. per dozen; Cucumbers, 3s. to 4s. 6d.; Lettuces, 9d. to 1s.; Evesham Beans, 3d. per lb.; Peas, 6s. per bag (40 lbs.); Mushrooms 2s. per lb.; Carrots and Turnips, 3d. per bunch; and Garlic, 2s. 6d. to 3s.

SCHEDULES RECEIVED.

ABERGAVENNY AGRICULTURAL ASSOCIATION.—Horticulture, etc. Exhibition, in Bailey Park, on September 5, 1929.—Secretary, Mr. H. J. Rice, Bro Dawel, Deri Road, Abergavenny.

THE NATIONAL CARNATION AND PICOTEE SOCIETY, NORTHERN SECTION.—Annual Exhibition, on Saturday, August 10, in the Lower Cutlers' Hall, Sheffield.—Secretary Mr. Wilfred Secker, 11, Longley Avenue, Norwood, Sheffield.

KING'S WALDEN HORTICULTURAL SOCIETY.—Twenty ninth Exhibition of Flowers, Fruit and Vegetables, on Wednesday, August 7, in the Park, King's Walden.—Secretaries, Mr. A. J. Hartless, The Gardens, King's Walden Bury, Hitchin, and Mr. W. G. P. Clarke, 4, York Road, Hitchin.

BLETCHLEY AND DISTRICT HORTICULTURAL SOCIETY.—Fifteenth Summer Show, on Monday, August 5, in Bletchley Park. Autumn Show on Friday and Saturday, November 8 and 9, in the High Street Schools, Bletchley.—Secretary, Mr. Hedley J. Clarke, Bletchley, Bucks.

EASTBOURNE HORTICULTURAL SOCIETY.—Summer Show, in the Manor House Grounds, on Wednesday and Thursday, August 21 and 22. Autumn Show in the Winter Garden, Devonshire Park, on Wednesday and Thursday, October 30 and 31.—Secretary, Mr. James Ticehurst, 4, Bakewell Road, Eastbourne.

THAME SHOW.—The sixty-ninth Annual Show, to be held at Thame, Oxon., on Thursday, September 19, 1929.—The Secretary, Thame Show, Thame, Oxon.

CATALOGUES RECEIVED.

STEWART AND CO., 13, South St. Andrew Street, Edinburgh.—Bulbs and roots for autumn planting, and for forcing for Christmas and winter bloom.

RYDER AND SON, LTD., St. Albans.—Bulbs, Flower and Vegetable Seeds and Seedling Plants for summer and autumn sowing and planting.

SUTTON AND SONS, Reading.—Flower and Vegetable Seeds for summer and autumn planting; Horticultural Sundries, etc.

J. R. PEARSON AND SONS, LTD., Lowdham, Notts.—Bulbs and Roots for summer and autumn planting; Sweet Peas, Strawberries, Flower Seeds for autumn planting, Garden Tools, etc.

LITTLE AND BALLANTYNE, LTD., Carlisle.—Bulbs, Plants for early forcing, Roses, Fruit Trees, Hardy and Ornamental Trees and Shrubs.

JOHN WATERER, SONS AND CRISP, Twyford, Berks.—Bulbs.

R. WALLACE AND CO., LTD., The Old Gardens, Tunbridge Wells.—Irises.

BARR AND SONS, Covent Garden, W.C.2.—Autumn and Winter-flowering Bulbs.

Foreign.

V. LEMOINE AND SON, Nancy, France.—Herbaceous plants, flowering shrubs, etc.

H. DEN OUDEN AND SON, Old Farm Nurseries, Boskoop, Holland.—Trees, Evergreen and Flowering Shrubs, Roses, Hardy Perennials and Alpines, Paeonies Irises, Hardy Ferns (Wholesale only).

ANTHONY ROOZEN, Haarlem, Holland.—Dutch Bulbs Herbaceous plants, Roses, etc.

GARDENING APPOINTMENTS.

Mr. P. Baldwin, for the past seven years gardener to Major Sir FRANCIS BURDETT, Bart., at Foremarke Hall, Derbyshire, as gardener to the same at Ramsbury Manor, Wiltshire. [Thanks for 2s. for R.G.O.F. Box.—EDS.]

Mr. Howard Grace, for the past three years gardener to Mrs. BONVILLE FOX, Brislington House, Bristol, and previously gardener to EARL TEMPLE, Newton Park, and Sir E. MOUNTAIN, Bart., Norbury Park, Dorking, Surrey, as gardener to the Rt. Hon. VISCOUNT EDNAM, Himley Hall, Dudley, Worcestershire.

Mr. E. Oovey, for the past seven years gardener to H. D. RYAN, Esq., Minley Grange, Farnborough, Hampshire, as gardener to Mrs. COURTENANY BRUCE, Brook House, Fleet, Hampshire.

COLOURED SUPPLEMENT PLATE.
Rose Flamingo.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 62·4°.

ACTUAL TEMPERATURE—
The Gardeners' Chronicle Office, 5, Tavistock Street Covent Garden, London. Wednesday, August 7, 10 a.m. (Greenwich time). Bar. 29·9. Temp. 60°. Weather, showery.

Hardy Fruit Crops of 1929.

THE unhappy climatic conditions that prevailed during a greater part of the flowering period of fruit trees led most gardeners to predict a bad or poor fruit year. That prediction, however, has not been entirely justified by the results, for while it must be admitted that 1929 is not a great fruit year, it is not a wholly bad one. It is a bad Plum year, but curiously enough, while such early-flowering subjects as Plums suffered badly during the severe weather of early spring, Peaches and Nectarines, usually regarded as more susceptible to unkind weather, appear to have escaped damage and are cropping well. In our own garden in West Middlesex, some Peach trees planted against a fence—and not too prosperous, owing to the draughty position—have been allowed to grow rather freely above the fence, because of the spring beauty of their abundant flowers. These unpruned branches, rising six feet above any protection, flowered beautifully, and are now carrying good crops of fruits. The Apple crop is moderate in most districts, very poor in others, and only very good in a few places. Pears are yielding better than was anticipated, and even where Apples are practically a failure, Pears often carry good crops. Cherries were good, but in quality rather than quantity, although the good old Morello Cherry has once again demonstrated its value as an unfailing cropper. Almost everywhere, the crops of small fruits have been excellent in quantity and quality; Black Currants have shown that they can withstand dry weather to an extent for which they do not usually receive credit; Raspberries, despite the dry weather, have also yielded well, so far as our personal experience goes, and Loganberries have maintained their reputation for consistent and abundant crops. The old-time popularity of the Apricot appears to have waned considerably and no doubt its uncertainty as a crop-producing fruit, coupled with its tendency to die, in part or in whole, without any obvious reason, has led to fewer trees being planted. A very pleasing inference to be drawn from the reports of our correspondents (pp. 112-118) is that Strawberries are regaining some of their wonted vigour; there is no doubt that the many troubles to which Strawberries have been subject during recent years are being combated with an increasing measure of success, thanks to the investigations made by the various research stations and the remedies suggested as a consequence. In short, there seems to be good reason for hoping that in a few years' time the cultivation of Strawberries will not be the difficult and exasperatingly disappointing task it has been of late. Home-grown Nuts do not occupy so important a position in the dessert as they did a couple of generations ago, owing to the large and varied imports, nevertheless, every gardener likes to be able to place good Cobs, Filberts and Walnuts on the table of his employer, but will be able to do so in very few cases this season, for once again it is a poor Nut year, Walnuts excepted. Before considering the Hardy Fruit Crop in greater detail we take this opportunity of thanking our numerous correspondents for the returns they have made. A few of the report forms sent out have not been returned, and a dozen or so were received at too late a date for inclusion in the tables which appear in this issue. The total number of reports received is two hundred. Our most important fruit crop, Apples, is under the average in quantity, as the reports show only 86 average and 15 "over" records, against 100 under the average. Pears make an even worse showing, taking the country as a whole, as there are 103 reports of "under" crops, 73 average and only 20 above the average. Out of the 198 records received only 10 show a crop of Plums above the average, and 56 indicate average crops, while the appalling number of 132 reporters have to record a deficiency. Cherries are better, as only 48 records tell of crops under the average, whereas there are 31 records of crops above the average and 104 of average amount. As already indicated, it is a good year for Peaches and Nectarines, for out of 136 records, only 15 are "under," while 66 are average, and no fewer than 55 "over." Small fruits make a very fine showing in the report tables and only 11 correspondents have to record crops below par, whereas 107 report average crops, and no fewer than 83 have been blessed with bountiful returns; the small fruits certainly have the best of it in this year's records. Although 75 reports indicate small crops of Strawberries there are 84 of average quantity and 34 above the average; in 1928 there were only 29 records of "over" crops, while the "under" crops numbered 80, and average 103, out of a total of 212 records. The total returns under Nuts show 46 average and only 12 "over" crops as compared with 1928, when there were no records of "over" crops, 23 average, and 72 below the average.

Our Coloured Supplement Plate.—The subject of the Coloured Supplement Plate which we have pleasure in presenting with this issue is the beautiful H.T. Rose Flamingo, which was raised by Messrs. Alex. Dickson and Sons, and was awarded the National Rose Society's Gold Medal on July 15, 1927, at the special show of new Roses held on that date. It is a very charming Rose, the blooms being well formed and shapely, especially in the bud, and very sweetly scented. It is after the type of the popular Rose Lady Inchiquin, and is regarded as an improvement on that variety. The colour is glowing, cerise-pink, deepening with age.

International Horticultural Exhibition at Courtrai.—An International Horticultural Exhibition is to take place at Courtrai, in Belgium, from September 14 to 16, this year. As its title implies, foreign exhibits as well as Belgian will be accepted, and all particulars are to be obtained from the Secretary, M. J. Callens, Grand Place 1, Courtrai, but applications close on August 15. There is a good choice of classes, which include greenhouse plants, all kinds of flowering plants in season, Dahlias, gardens, fruits, vegetables, wines, sundries, etc. Various bands have been engaged to play during the exhibition, and the proceedings will close with a dance at the Communal Theatre on the night of Monday, September 16.

A Series of National Parks.—The movement to establish a series of National Parks in this country, which originated in a letter by Lord Bledisloe written to *The Times*, in which he proposed the conversion of the Forest of Dean into a National Park, would appear to be widespread, and many prominent personages are taking an active interest in the scheme. Several natural beauty spots have already been suggested as suitable for the purpose, including the lovely vale of Dovedale, in Derbyshire, and the scheme is to be made the subject of a conference shortly. In the creation of National Parks, America has long led the way; at the present time America has nineteen National Parks, which embrace a total area of seven million acres and 160 National Forests covering 159 million acres, the primary objects of these national parks and forests being to foster the natural beauties of the areas and for the production of timber. What, exactly, will be the principles governing, and the purposes of, the proposed National Parks in this country, have yet to be clearly defined.

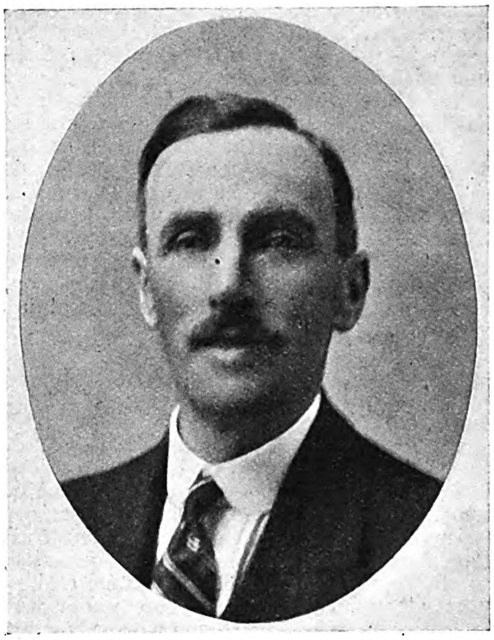
"Hardy and Half-hardy Plants."—Parts 3 and 4 of Vol. I, for July and August, respectively, of Mr. A. W. Darnell's new work, maintain the high standard of production of the previous publications. Abelia floribunda is the subject of a coloured plate in Part 3, the other illustrations in this issue being of Anemone palmata, Blechnum penna-marina, Buddleia Colvillei, Convolvulus sabatius, Cypripedium passerinum, Gazania pygmaea, Iris Milesii, Lewisia cotyledon, Lilium rubellum, Linnaea americana, Lobelia Kalmii, Meconopsis punicea, Pentstemon Scouleri, Phyteuma comosum, Pyrola chlorantha, Pyxidanthera barbulata, Rhododendron Schlippenbachii, Rubus parvus, Silene caroliniana, and Sisyrinchium filifolium; a very interesting set. Part 4 contains excellent illustrations of Clematis macropetala (coloured), Asplenium fontanum, Calceolaria biflora, Campanula macrorhiza, Cypripedium luteum, Davidia involucrata, Fremontia mexicana, Helichrysum grandiceps, Heloniopsis grandiceps, Incarvillea variabilis, Iris foetidissima, Lathyrus splendens, Mimulus brevipes, Mitchella repens, Oxalis enneaphylla, Primula Allionii, Rhododendron Baileyi, Rubus geoides, Salvia patens, Tulipa Clusiana and Viola rhodopeia.

Rose Show at The Hague.—The Rose Show which was held at The Hague, Holland, on July 19, 20 and 21, was well attended and highly successful. The opening ceremony took place in one of the halls of the Zoological Garden, an interesting speech being made by Mr. G. A. van Rossem, the Vice-President of the Association responsible for the arrangements. He spoke feelingly of the loss sustained to Dutch horticulture by the sudden death of the late Jhr. Mock, who had taken so large a part in Dutch nursery activities. The exhibits were beautifully arranged and made a most pleasing impression. The most important group was that of the firm of G. A. van Rossem, of Naardem, but so far as quality was concerned it was difficult to discriminate, and the exhibition as a whole reflected the greatest credit both on the organisers and on those who, in a late and difficult season, were able to assemble such a fine display.

Colour Film of Aquatic and Waterside Plants.—Mr. Amos Perry will give a lecture at the Royal Horticultural Society's fortnightly meeting, on Tuesday, August 13, at 3 p.m., on "Aquatic and Waterside Plants." A film, taken by the Koda-colour branch of Messrs. Kodak, in colour, depicting aquatic plants growing in a number of well-known gardens, will be displayed. As it is believed that this is the first occasion such a colour film has been exhibited for the purposes of a horticultural lecture, and as it will be of an instructive as well as an attractive character to a great number of horticulturists and to those interested in colour photography, any person interested in the lecture and display will obtain free admission to the lecture on application to the Secretary, R.H.S., Vincent Square, Westminster, S.W.1.

Scottish Potato Trials.—On the invitation of the Department of Agriculture for Scotland, a representative company of farmers, merchants, raisers and others interested in the Potato industry attended the annual demonstration of new seedlings at the trial plots situated at East Craigs, near Edinburgh, on Friday of last week. Mr. Anderson and Mr. Miller represented the Department and supplied the information regarding the work on hand. With reference to the certification of pure stocks suitable for use as seed sets, it was mentioned that the new special stock of Golden Wonder grown by Mr. John Chisholm, at Ladysbridge, Banff, represented a noteworthy achievement in the production of seed Potatos. This stock was described as "unequalled in the British Isles," and being free from serious Mosaic disease should be a strong attraction to growers producing for the "ware" market. It is also interesting to note that in one at least of the stock-seed plots of King Edward, one or two of the tubers failed to produce plants. These tubers were found to be affected with the fungus disease known as Skin Spot (Oospora pustulans), which usually takes the form of small, dark-brown pimples on the skin of the tuber. When a tuber is badly affected the fungus spreads over the eyes and kills them, thus preventing growth. This disease does not make its appearance until the spring, and its presence until then is unsuspected. It has been quite prevalent recently and seems to be definitely associated with certain fields. Commenting on registered varieties not having met with immediate satisfaction, it was explained that blemishes have appeared which were not sufficiently apparent during the testing period. The market was the best judge regarding the general attributes of a new variety, and the work of the Synonym Committee could only be regarded as a guide. The members, however, realised in what respects its testing methods required improvement, and action is being taken, or is contemplated, in respect of tests for (1) earliness; (2) cooking quality; (3) keeping capacity; and (4) resistance to disease—particularly Blight, Black-leg and Mosaic. Interest centred chiefly in the third-year trials where D1, raised by Mr. W. B. Pollock, was beaten in the early section by Ninetyfold, and was about equal to Duke of York. In the second-early and maincrop sections there were three seedlings of promise, viz., Alannah, sent by Sir Josslyn Gore-Booth, Sligo, which resembles British Queen in appearance and habit of growth, but is quite distinct; Dunbar Cavalier, which resembles King Edward in appearance, and Mr. McKelvie's No. 675, which is a cross between Flourball and Golden Wonder. The last two varieties are noteworthy for their fine cooking quality. In the second year trials the seedlings that secured favourable comment were No. 7,252, a second-early raised by Messrs. McGill and Smith, Ayr, and the following maincrop sorts:—H 326 (Messrs. Dobbie and Co.); Q. (Messrs. Alexander and Brown); A 596 (Mr. D. McKelvie); and 11,254 (Messrs. McGill and Smith). The main-crop section in the first-year trials was noteworthy for the five seedlings submitted by the Scottish Society for Research in Plant Breeding. All five seedlings are tall, vigorous and free from all symptoms of virus diseases. In the preliminary tests they exceeded Kerr's Pink in yield, and were considered equal to that variety in cooking quality.

Mr. William H. Holloway.—Visitors to the meeting of the Royal Horticultural Society held on Tuesday, July 30, who admired the fine fruit trees in pots exhibited from the gardens of Samuel Wallrock, Esq., The Manor House, Stanmore, will probably like to know something about the very able gardener who grew them. Commencing his gardening career at The Rectory, Monk Sherborne, Basingstoke, Mr. Holloway subsequently gained experience at The Vyne, Sherborne St. John, also at Basingstoke, and subsequently served under Mr. F. Streeter, at Hewshott House, Liphook, with whom he remained for three years. His next position was at Sir Randolf Baker's garden, Ranston, Blandford, where he stayed for three years under Mr. A. E. Usher, and naturally became fully acquainted with the high-class cultivation of Sweet Peas. From Ranston he passed on to Basing Park, Alton. Then came the War. For a period of four years and ten months Mr. Holloway served with H.M. Forces. After demobilisation he entered the service of Colonel G. L. May, and remained with him as gardener at Down Grange, Basingstoke, for six years. His next appointment was with Lady Louth, Summerfield House, Elstree, and in June, 1926, he took up his present position at a time when Mr. Wallrock was developing his extensive garden-planning operations at Stanmore. Both Mr. Wallrock and Mr. Holloway are keen exhibitors, and they have already a notable list of successes, especially when it is remembered that the garden at Stanmore is only nine years old, and developments are still continuing. In 1927, they obtained twenty first prizes, two Challenge Cups, a large Gold Medal and a Banksian Medal at the Elstree show, besides nineteen first prizes and two Challenge Cups at the Watford show, and twenty-one first prizes, three Challenge Cups and a Silver Medal at the Bushey Heath show. In 1928, their record at Elstree was twenty-three first prizes, two Challenge Cups and a Gold Medal, and, at Watford, thirty-one first prizes and two Challenge Cups, in addition to a piece of plate, while at Bushey Heath they secured nineteen first prizes, four Challenge Cups and a Silver-gilt Medal. Successes obtained this year prove the consistency of Mr. Holloway's skill as a cultivator and they include twenty-five first prizes and three Challenge Cups at Elstree; twenty-five first prizes and two Challenge Cups at Watford, and seventeen first prizes, two Challenge Cups won outright, and a Gold Medal at Bushey Heath Show on August Bank Holiday. In addition, the Stanmore produce has won a Challenge Cup at Harrow this year; seven first prizes, the E. W. King Cup and a Banksian Medal at Norwich; seven first prizes, one Challenge Cup and a Banksian Medal at Windsor; the Silver Medal for Cinerarias, and a Silver-gilt Medal for Schizanthuses, as well as the Gold Medal for pot fruits, all from the Royal Horticultural Society; and the National Sweet Pea Society's Bournemouth Cup at that Society's London Exhibition. This wonderful list of successes leads us to anticipate great things in the future from The Manor House gardens, where both Mr. Wallrock and Mr. Holloway combine to produce a garden of great taste and beauty, and flowers, fruits and vegetables of the very highest quality.



MR. WILLIAM H. HOLLOWAY.

Gentiana hascombensis.—Mr. C. T. Musgrave, of Hascombe Place, Goldalming, informs us that the handsome and vigorous hybrid Gentian he raised between G. Lagodechiana and G. septemfida var. cordifolia, is to be known as G. hascombensis (Fig. 50). Mr. Musgrave exhibited the plant at the meeting of the Royal Horticultural Society on July 30; it was described in *The Gardeners' Chronicle* of August 3, p. 96.

Kew's Place in the System of Agricultural Bureaux.—The majority of our readers are aware of the wonderful work accomplished by Kew and Kew men in developing the economic resources of the Empire; they will, therefore, be interested to learn what the Ministry of Agriculture has to say regarding the Royal Botanic Gardens and their place in the system of Imperial Bureaux established for the centralisation and distribution of information on agricultural subjects, a system that has recently received considerable expansion as a result of the recommendations of the Imperial Agricultural Research Conference, 1927. In this connection the Ministry states in its *Journal* for the present month that: "Kew fulfils the functions of a Bureau of Botany in all its aspects. On the economic side it has for many years been actively engaged in obtaining from all parts of the world plants of potential economic value, and in the propagation and distribution of these for experimental cultivation in the Dominions and Colonies. Funds have recently been placed at the disposal of the Ministry of Agriculture by the Empire Marketing Board to enable Kew officers to visit overseas parts of the Empire to advise the Governments concerned on botanical and agricultural problems. A botanical survey of the Empire, the fundamental basis for the development and exploitation of the natural vegetable resources, has been continuously in progress for upwards of three-quarters-of-a-century. The Governments of India, the Union of South Africa, and the West African Colonies maintain officers at Kew for the study of botanical problems of these particular areas, and negotiations are in progress for the interchange of scientific staff between Kew and other parts of the Empire."

Earthquake in New Zealand and its effect on Vegetation.—Through the kindness of Mr. Lionel de Rothschild we are able to publish the following extract from a letter by Mr. Edgar Stead, of Ilam, Riccarton, New Zealand, dated June 23, 1929:—From a horticultural point of view the big shake was very interesting. I was standing talking to one of my men on the other side of the stream, about eighty yards from the house, when the first tremble came. This was very slight, and ceased for some seconds before starting again with more vigour. I immediately moved that I might get a good view of the house to see how it fared. The 'amplitude' of the movement was big, but the 'frequency' low, and the motion was nice and smooth (like a long swell at sea) not jerky, and it is doubtless to this that the smallness of the damage may be ascribed. We could plainly see the earth heaving at the top of the terrace above the stream, just as one sees the surface shake when 'quaggy' ground is jumped on. The Azaleas on the bank began shaking their heads vigorously; indeed, one ten feet bush which I watched closely was moving far more than a man could have made it do. Then the big trees began to wave, and when the shake had been going for about half-a-minute and was at its height, the effect was positively amazing. The tall Lombardy Poplars near the house were whipping to and fro as if lashed by a gale, while a row of tall Pinus insignis was dashing about so that it looked as though they simply must break. In the big Black Poplar plantations the trees were banging against one another and knocking off small branches, and a similar state of affairs in a grove of Pinus maritima produced a rain of cones. The Oaks on the lawn, however, behaved in an entirely different way. No doubt they started to sway at the beginning of the 'quake, but owing to the rigidity of their stems and their very wide-spreading heads, they quickly took on a twisting motion as well as a swaying one. It will give you some idea of the amount of motion there was among the trees when I tell you that the height of the tree-background to the house was appreciably reduced, so that the building itself seemed to stand up abnormally high, the solitary thing in sight in which we could detect no movement. I confess I was expecting to see the house collapse at any moment, but it did not even crack, and nothing of importance was shaken down inside. My apprehension would have been much greater had I known my wife was inside. I thought she was in town, but she had not gone, and stayed upstairs with a maid, whose knees gave way, and who just hung on to the banisters. I went to the edge of the terrace and looked at the stream. I found no difficulty in walking, although, when standing still, I had thought I should do so. Where I stood on the bank, the stream takes a curve, and the whole surface of the water was much agitated, and mud was being stirred up from the bottom. In the small section of the stream which ran approximately east and west the water had a fine surge on and was slopping up on the banks a foot high. The day was calm, scarcely a breath of wind—and it produced an extraordinaily eerie effect to see all the trees being hurled about, without the accompanying roar of a hurricane—there was not much of a rumble, and only a loud rustling noise from the trees. I put it down as quite one of the most interesting and thrilling things I have seen in my life. Near the centre of the disturbance, trees were snapped off or tossed out, roots and all. A timber expert states that all the timber of that area will probably exhibit 'shakes' (cracks) in it as a result of the abnormal stresses to which it was subjected.

Flora of the Imatong Mountains.—In February, 1928, Major T. F. Chipp, Assistant Director of the Royal Botanic Gardens, Kew, paid a visit to the Imatong Mountains, Sudan, and collected about one hundred species of plants in a district not previously explored; indeed, no collections have been made hitherto on the high mountains immediately north of the Sudan-Uganda border. An account of the trip appears in the Kew *Bulletin* (No. 6, 1929), together with an enumeration of the specimens collected, observations on the phyto-geographical affinities of the flora of the Imatong Mountains, and descriptions of half-a-dozen new species discovered. These last are Combretum laboniense, Craibea utilis, Belonophora glomerata, Coreopsis Chippii, C. tripartita and Lobelia dissecta.

Legacies to Gardeners.—The late Edmund William Rickett, of Hillerton Cross, Bow, Devon, who died on March 13, 1929, left £100 a year to his head gardener, Mr. William Penney, so long as he shall reside with his wife, or if she shall survive him, £60 a year to Sarah Penney, and £26 per annum to Mr. John Lee, gardener at Spreyton, Devon.

A Method of Scaring Birds.—Mr. S. Leonard Bastin recently published an account in *The Field* of a successful method employed at an American plant research station for the scaring of birds from gardens and orchards. It is claimed that the majority of the mischievous birds in gardens, and especially sparrows, have a particular horror of blue paper, and the tests carried out in America would appear to verify this statement. Seed-beds had lengths of twine stretched across them and to these were attached strips of bright blue paper with the result that the birds left the beds severely alone, while the beds of Crocuses which had formerly suffered severely from attacks by sparrows were saved by pieces of blue paper held above them in cleft sticks. It is also stated that fruit trees and bushes can be perfectly protected from the ravages of birds by tying strips of blue paper or cloth at intervals along the branches. It would appear that birds do not overcome their fear of blue as they do of ordinary bird-scarers, and we suggest that readers who are particularly troubled with the ravages of birds might well give this method a trial.

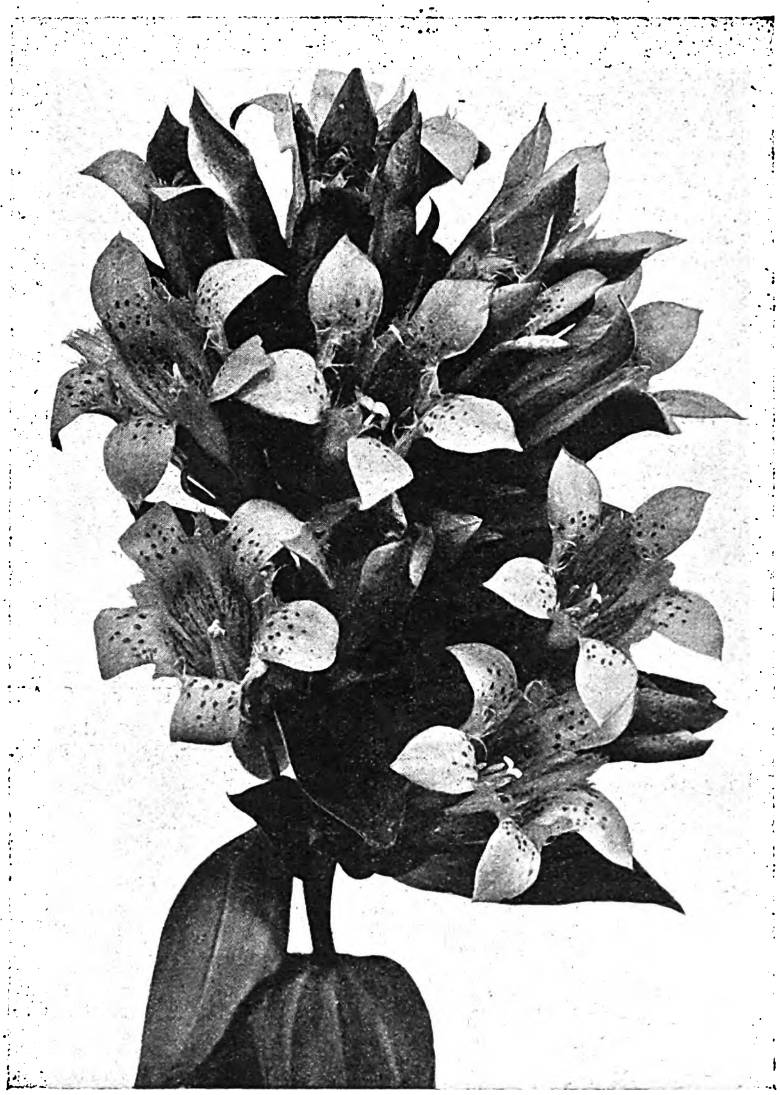


FIG. 50.—GENTIANA HASCOMBENSIS.

R.H.S. Award of Merit, July 30. A hybrid between G. Lagodechiana and G. septemfida var. cordifolia Flowers blue and white. Shown by Mr. C. T. Musgrave, Hascombe Place, Godalming. (see pp. 96 and 102).

Appointments for the Ensuing Week.—Tuesday, August 13: Royal Horticultural Society's Committees meet; Jersey Gardeners' Society's Exhibition; Clay Cross Floral and Horticultural Society's Show. Wednesday, August 14: Taunton Dene Horticultural Society's Exhibition (two days); Sheffield Chrysanthemum Society's lecture; Banff Horticultural Society's Exhibition. Thursday, August 15: Scottish National Sweet Pea, Rose and Carnation Society's Exhibition (three days); Aberdeen Royal Horticultural Society's Exhibition (three days). Saturday, August 17: High Wycombe and District Horticultural Society's Exhibition; Dumbartonshire Sweet Pea Society's Exhibition; L.M.S. Federation of Horticultural Societies' (North-east Section) Annual Exhibition; Leeds Paxton Society's Sweet Pea Show; Charfield Flower Show; Hemel Hempstead Horticultural Society's Summer Show; Highfield (Leicester) and District Gardening Society's Exhibition.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Clerodendron Bungei, alias foetidum.*—Perhaps "A. H." would like to know that a plant of the above survived a sharp winter in Messrs. Standish and Noble's nursery at Bagshot, and pushed up strong shoots from the roots in the spring. This was without any protection. All above ground in the winter was destroyed. M. Ortgies, of Ghent, M. van Houtte's representative, informed me a few weeks since that it is also quite root hardy in Belgium. I think it about as hardy as a Fuchsia. In lately noticing the plant in the *Chronicle*, you said, "If we can trust a figure of it published in the 'Flore des Serres,' it must be remarkably handsome." The drawing for that plate was made by me, and if (as I am assured, for I have not seen the plate) it is a correct copy, I can vouch for its accuracy to nature in size, form and colour. The plant from which the drawing in question was taken had four such corymbs, and was clothed with its large, handsome leaves to the rim of the pots. If well-grown, and it requires very liberal treatment, it is indeed very handsome; if starved, it degenerates to a scarecrow. The flowers are very sweet-scented. I should add that a plant which flowered in Belgium was quite equal to the drawing made here. *George Lovell. Gard. Chron., August 12, 1854.*

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Manchester

The Cattleya House.—The various plants in this house are in different stages of growth; plants that have just passed out of flower and are in need of repotting should receive attention so soon as they commence making new roots, at which stage, if the plants are disturbed, they will soon recover and establish themselves much better than if the repotting is done regardless of the condition of the roots, and simply because it is the potting season. Provided the compost is not in a sour state, it is best to defer repotting until the production of fresh roots has commenced, no matter at what season of the year this may be. Some kinds have to make their growth after flowering and these will require plenty of water and generous treatment so soon as they have become established in the new compost. Such sorts as C. gigas and C. Warnerii will require to be kept on the dry side, just sufficient water being given to keep the pseudo-bulbs plump and encourage root action, and when re-established, more air and sunlight should be allowed to reach the plants in order to thoroughly ripen the growths and assist in keeping the plants in a dormant condition until they commence to grow naturally again in the spring. Unless the pseudo-bulbs of vigorous kinds such as C. gigas are well matured and ripened now, successful flowering cannot be expected next year. Other kinds are now growing fast and developing flower sheaths, and those varieties that produce their gorgeous flowers on completion of the growth, notably C. Hardyana and the many hybrids—Laelio-Cattleya Profusion, etc.—should be given a light position where a free circulation of air can be maintained on all favourable occasions, and as much sunshine as the leaves can withstand without injury. A good guide in this respect is that shade is required when the leaves feel hot when touched by the hand; the danger of scorching the foliage is not great when plenty of fresh air is circulating around the plants, but great fluctuations of temperature should be avoided so much as possible. A buoyant atmosphere should be maintained, sufficiently charged with moisture to promote growth; if harsh and dry conditions are allowed at this season the growths may receive a check and become stunted, with the result that deformed flowers] will be produced. As the growths advance and are nearing completion root action is generally increasing, therefore ample supplies of water are needed each time the compost approaches dryness until growth is complete, and if flowers are produced immediately, sufficient water should be given to allow for their full development, when drier conditions should be afforded.

Species and Hybrids.—Numerous species and hybrids will complete their growths and sheath now, but do not produce flowers until a later date. These sorts should receive generous treatment as to water, etc., until growth is complete, when only sufficient is required, at long intervals, to keep the pseudo-bulbs and roots in a plump condition. In the Cattleya group there are always individuals that call for special treatment in some detail, therefore no hard and fast rules can be laid down for their treatment; the grower has to use his discretion in these matters. Where Cattleyas, etc., have to be grown in the same division as Cypripediums or other moisture-loving Orchids, some difficulty is often experienced in ripening the growths well without exciting them into growth again. Better results are obtained if the plants can be removed to a division with a night temperature of 55° to 60°, where they can be kept drier and more air allowed, with plenty of sunlight, to strengthen the growths. Where a division is devoted to these plants their requirements are more easily maintained, as maturing plants can be kept together and treated accordingly.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Frost Damage to Fruits.—In the plantations here I have noticed that quite a number of Apples are badly marked with a brown russetting which was caused, no doubt, by spring frosts. The blemishes are only skin deep and are on one side, but they are not uniform, for some are near the eye, some at the stem end, and some on the side. Except with dessert varieties, this may not be a serious matter to the private gardener, but to the market grower, however, it must lower the value of the product very considerably.

Birds and Apples.—Birds are attacking the Apples earlier than usual this year, owing, no doubt, to the long-continued drought and lack of moisture. It shows remarkable instinct, for the birds invariably select soft-fleshed varieties, such as The Rev. Wilks, White Transparent, Lord Suffield and The Queen. Preventive measures in the case of bush trees are almost impracticable, and it is unwise to remove the attacked fruits, as the birds will then attack the sound fruits and increase the evil. Pears and Plums on walls should be protected by netting as a preventive measure against birds, particularly tits, which are most persistent in their attack upon Pears and other fruits.

Woolly Aphis.—This malignant pest is too frequently seen in gardens now-a-days, and there can be no doubt that it is the precursor of canker in Cox's Orange Pippin and other susceptible varieties of Apples. The trees should be gone over, branch by branch, and any trace of the pest, which is readily recognised at this period by the white, woolly substance excreted by it, should be eradicated by means of a painter's brush and methylated spirit, or a soft-soap and nicotine wash. Affected standard trees and those out of reach should be sprayed with a soft-soap and nicotine wash made up of 2 lbs. to 3 lbs. of soft soap and one-and-a-half ounce of pure nicotine to twenty-five gallons of water. This should be sprayed on with some force through a coarse nozzle.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Melons.—After this date, the nights will commence getting longer and colder, and calculations as to the time of ripening, and the quality of the Melon fruits, will be uncertain. Few persons care for late Melons, but the scarcity of choice Apples and Plums will justify an attempt to keep up a supply until November. Plants put out early in July will ripen their fruits in September, and seeds sown before the end of the month should provide plants which, under good ordinary management, should carry the supply through October. Of two evils it is better to sow rather early than too late, as October Melons come on slowly; but provided they are sound and of medium size they can be kept some time in a dry fruit-room or dry vinery. Light and heat are essential, but large masses of compost which cannot be dried and warmed quickly are objectionable, and for these late crops pots are to be preferred, as they can be plunged in a sharp bottom-heat, which can be renovated when necessary, the most critical periods being the setting and ripening of the fruits. Many state that all Melons are good when properly cultivated, but many of us have much to learn with regard to Melon-growing, and possibly the greatest mistake is that of over-feeding and allowing the bottom-heat to fall too low at the finish.

Cucumbers in Frames.—Cucumber plants in frames have done well, and those in full bearing may be well watered twice a week, well syringed overhead on alternate days, and the frames closed early to induce quick growth of both vines and fruits. If red spider or mildew attacks the plants, look to the outside linings and remove a few of the old leaves preparatory to the application of sulphur or sulphur-water, the best and safest remedy, always provided the lights are tilted early on bright mornings and lightly shaded during the day. It is not from the application of sulphur, or fumigation in a mild form that the plants suffer, but from a few minutes' neglect when the sun strikes the closed lights the following morning.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Bulbs for Forcing.—To be successful in the early forcing of such bulbous subjects as Roman Hyacinths, Paper White Narcissi, Tulips and Freesias, much depends on the condition of the bulbs procured, and if the bulbs have been specially grown for this purpose and are obtained from reliable sources, a large degree of success is assured. Orders for bulbs should be placed at once, and the bulbs, upon arrival, should receive immediate attention with regard to potting. After being potted they should be plunged in leaf-mould or ashes in a somewhat shady place until such time as growth is active, when they should be gradually exposed to the light and placed under warmer conditions in batches to keep up a continuous supply of flowers.

Freesias.—If a stock of home-grown corms is at hand, they should be shaken out of the old soil, graded and repotted. The largest bulbs should be selected for this purpose, and eight or ten bulbs placed in a four-and-a-half-inch pot. Ordinary potting soil should form a suitable rooting medium, and this should be pressed firmly about the corms. When potted, they should be placed in a cold frame and shaded from bright sunshine. Keep the soil just moist and admit air freely.

Primula sinensis.—So soon as the Primula sinensis seedlings are large enough to handle they should be placed singly in sixty-sized pots filled with a compost consisting of loam and leaf-mould in equal parts, lightened by a good sprinkling of silver sand. Place the roots well down in the soil so that the collar of the plant is just below the surface. Dust the surface of the soil with sand, then place the young plants in a cold frame, taking care to shade them lightly from the direct rays of the sun. Never shade them heavily for this will cause weakly growth. When the seedlings have filled these receptacles with roots, pot them on into four- or five-inch pots, in a compost of fibrous loam and leaf-mould with some spent Mushroom-bed manure or dry cow manure, broken charcoal and sand added. Water them carefully at all times—this is one of the most important details in their culture—and as the pots become well filled with roots, give applications of soot-water and weak liquid manure.

Gloxinias.—As the early plants pass out of flower they may be placed in cold frames and watered regularly until the foliage shows signs of dying, when watering should be withheld gradually. Young plants that were raised this spring will now have filled their receptacles with roots, and may be assisted with light doses of liquid manure; strong manures are not to be recommended, as their application has injurious effects upon the keeping qualities of the corms.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Leeks.—The main crop of Leeks should now be ready for planting out; allow sixteen inches between the lines and nine inches between the plants. When planted, water them in well if necessary, and hoe the surface of the bed frequently and regularly.

Onions.—The bulbs of these are now swelling and the tops may be turned down to encourage this process. Keep the bed free from weeds, pulling them by hand, and see that the Onions do not suffer through lack of water at this stage of growth; water them regularly if the soil is inclined to be dry, and afford stimulants in the form of liquid manure once every week.

Broccoli.—Further plantings of Broccoli may be made on any vacant ground. Give the plants every encouragement after planting by plying the Dutch hoe between them frequently, and so soon as they are of moderate stature, draw some soil about their stems to secure them against wind.

Seed-sowing.—Further sowings of Lettuces, preferably of black-seeded varieties, may be made in drills fifteen inches apart; sow the seeds thinly, and subsequently thin the seedlings to ten inches apart. For frame culture, sowings of Lettuces may be made now in an open border, transplanting the seedlings into frames when of convenient size, or the seeds may be sown in lines in the frames and the seedlings thinned to a reasonable distance apart when practicable. Further sowings of Radishes and Mustard and Cress should be made to provide successional supplies. Cultivate the ground well and make the surface as fine as possible before sowing the Radishes.

Late Peas.—Attend to late Peas, and if they are breaking away from the sticks, tie them in well. Should hawfinches prove troublesome protect the Peas with nets.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Lilium candidum.—When it becomes necessary to replant clumps of this Lily that have become over-grown, do not delay the work after the foliage has died down. Root action commences practically immediately the foliage had died down in this Lily, therefore no time should be lost if transplanting is contemplated. L. candidum thrives in any ordinary garden soil and dislikes being coddled and disturbed, the best examples being seen in cottage gardens where they have been undisturbed for years. If new plantations are being made, trench the site, but do not add fresh manure, old turfy loam being preferable. When planting, surround with, and rest each bulb on a bed of, sharp sand. In soils which are inclined to be wet during the winter I have found it a good practice to rest each bulb on a number of small stones; such a method insures the drainage of superfluous moisture from about the bulbs.

Myosotidium nobile.—This native of the Chatham Islands is really only of value as a hardy plant in the more favoured parts of the country. Where such conditions exist it is a plant well worthy of a specially prepared position. It has large, glossy, Funkia-like leaves of a bright green. The flowers suggest those of a giant Forget-me-not, in various shades of blue and borne on stems from two to three feet in height. Being found on sea-shores, it should be planted in a bed composed of practically pure sea sand, in which its thick root-stock will soon become established. A top-dressing of decayed seaweed has been found beneficial in promoting luxuriant growth. Incidentally, mice are extremely fond of the seeds, even before they are ripe.

Crocus species.—These are not so well-known in gardens as they deserve. The usual practice when planting Crocuses is to put in a number of the Dutch forms, but valuable as these are for making beds or banks gay during spring, their beauty cannot compare with that of the charming kinds found among the species. These, also, have the added advantage of flowering during autumn, winter and early spring, and are admirably adapted for growing in pockets in the rock garden. They are best planted under a carpet of some other plants, so that the blooms may be protected from being soiled during stormy weather, and so that no bare patches are visible after the Crocus flowers are past. Many dwarf alpine plants suggest themselves for this purpose. Arenaria balearica, Acaenas, the dwarf, mossy Saxifrages and numerous others, make admirable carpets and associate well with the Crocuses. Some of the smaller sorts are perfect gems and deserve special attention and positions where their enchanting loveliness may be fully appreciated. Others are so inexpensive that they may be used for naturalising in grassy banks, where they will form delightful pictures. The corms should be planted so soon as they can be procured; many kinds can be had during late July and August and if blooms are expected the first season, they should be planted at once. Autumn-flowering species include C. longiflorus, with soft, rosy-lilac flowers; C. nudiflorus, common in many parts of the country; and C. Salzmannii, which will naturalise itself under good conditions, and of which there are several varieties differing in shades of colour. C. Clusii, C. zonatus, C. sativus, C. ochroleucus and C. speciosus are all worthy of a place for autumn and early winter flowering. Other lovely species which will extend the flowering into the spring, are C. Imperati, C. Susianus, C. versicolor, C. Tommasinianus, C. Sieberi and C. chrysanthus.

Olearia stellulata.—The Olearias suffered considerably last winter, and many of the more tender varieties have been killed. O. stellulata came through the winter as successfully as the well-known O. Haastii, which seems nearly as popular in town gardens as Aucuba japonica. O. stellulata is a delightful plant, with its grey foliage and myriads of white flowers. Some confusion seems to exist between this and O. Gunnii, but when the two true forms are grown side by side the former is freer flowering and, in my experience, a little hardier. O. stellulata may be increased quite easily by inserting cuttings during August or early September, and these should make good plants for planting out in the spring.

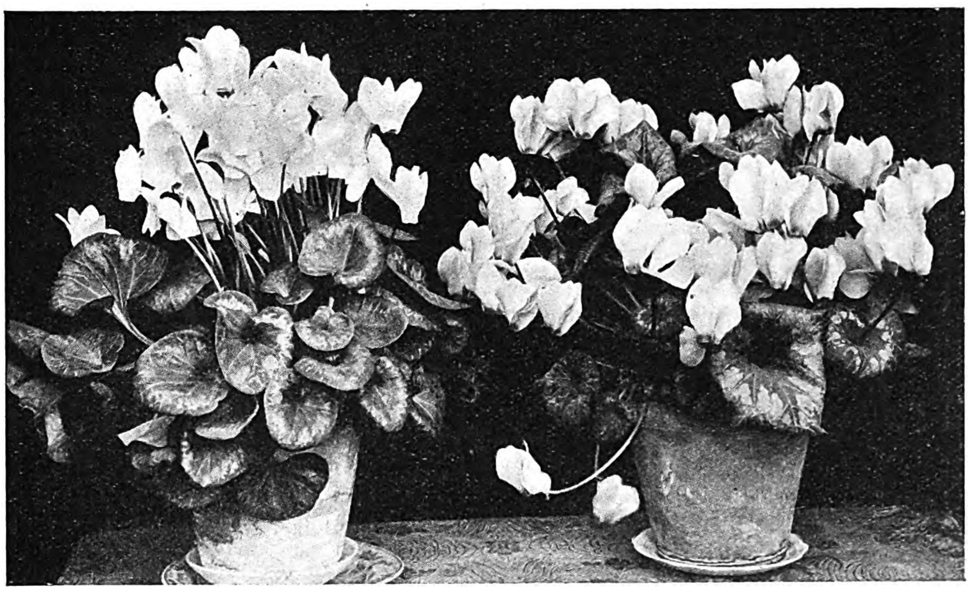

FIG. 51.—CYCLAMENS IN A COTTAGE WINDOW.
(see p. 110.)

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Violets.—The continued dry weather has been trying for these, unless they were planted in semi-shaded borders or daily syringings have been given. Deep cultivation of the site during winter where these are to be grown is necessary for their successful cultivation; the value of this is obvious during prolonged droughts. A thorough watering should be given, afterwards hoeing the surface to conserve the moisture; mulching with well-decayed leaf-soil or vegetable matter will be found beneficial; here, we find spent Hops useful material for this purpose; it is light, does not form a close mass, and yet prevents evaporation. A weekly dusting of soot will help to prevent attacks by red spider, which is so partial to this plant during dry weather. See that the undersides of the leaves are dusted and apply it only when the plants are damp so that the soot adheres to the leaves. No runners should be allowed to grow, the object being to build up strong crowns by early autumn before transferring them to their winter quarters in frames.

Romneya Coulteri.—Among hardy plants, few surpass the lovely Californian Poppy in beauty. In favoured districts this makes wonderful specimens in the open, but where climatic conditions are less favourable it is well worthy of the protection of a wall with a south or south-western aspect. It does best in light, warm soils, and where the natural soil is heavy, a position should be specially prepared for it by adding some light, sandy compost. A successful method adopted where the soil was of a heavy texture was placing flat stones of various sizes throughout the bed as it was prepared. The system seems to suit the plant admirably, the long, thong-like roots finding their way under the flat stones, and suckers springing up freely at some distance from the old plant. As a group for a hot, sunny position on the lawn, where it does well in the open, it is ideal. A mulch of some light, porous material over its roots during winter is advisable. Propagation is effected by seeds or cuttings; root-cuttings inserted in the spring make the best plants.

Celery.—In many districts the Celery crops have been attacked in recent years by a most destructive fungus or rust, which at once checks the growth of the plants and spreads with alarming rapidity. The appearance of this disease should be watched for, and the whole crop sprayed with lime-sulphur, one part to one hundred of water, repeating the application at intervals of a week until no trace of the disease remains. I am experimenting with ammonium polysulphide, which seems, so far, to be a good fungicide, but expensive in comparison with lime sulphur.

Cyclamens.—Seeds of Cyclamens should now be sown to produce flowering plants for next year. Pans or shallow boxes, well drained and filled with a light compost of leaf-mould, loam, sand and charcoal, passed through a quarter-inch riddle, using all the rough parts over the drainage, are suitable. Place the seeds regularly all over the surface, press them well down and cover with a layer of soil or sifted Cocoanut fibre. Water the seed-pans well and keep them in a temperature of at least 60° until germination takes place.

FLOWER GARDEN.

ASPERULA ORIENTALIS.

Some confusion would appear to exist as to the correct name of this charming little annual Woodruff. In catalogues it usually appears under the name A. azurea-setosa, or sometimes A. setosa-azurea. In the Kew *Handlist of Rock Garden Plants* it is given as A. azurea, while in the *Index Kewensis* it is referred to as A. orientalis, under which name Bailey also describes it in his *Cyclopedia of Horticulture*. It would appear, therefore, that its correct name is Asperula orientalis.

However, apart from the confusion in nomenclature, this charming hardy annual is a very attractive little subject, and suitable for a variety of purposes, for it forms a bushy mass nine inches or one foot high, of slender, branching growths, furnished with lanceolate, bristly leaves usually in whorls of eight, the little branchlets being terminated by small heads of light blue, sweetly-scented flowers, which are produced in succession over a long period.

As a ground-cover for large beds, with tall "dot" plants here and there, A. orientalis is very effective, and it may also prove valuable where the soil is on the poor side, while it is worthy of note that the dainty blue Woodruff does not object to slight shade, such positions often presenting problems to the gardener. To those who do not object to the use of annuals on the rock garden, A. orientalis can be recommended as very suitable for filling bare spaces.

As stated, it is a hardy annual, so that, if an early display—in April and May—is desired, seeds may be sown *in situ* in the autumn, the plants, although native to the Orient, being capable of surviving our winters, while for a summer and autumn display, seeds may be sown in spring, the plants being afforded the usual treatment recommended for hardy annuals in the matter of thinning and cultivation. *W.*

ALPINE GARDEN.

ONOSMA HELVETICUM.

Although O. helveticum is not so effective a plant as O. tauricum, which it resembles in the colouring of its flowers, it is yet quite a useful subject for the rock garden, as it produces its tubular, creamy-yellow flowers, up to one-and-a-quarter-inch in length, during the height of summer.

In habit of growth this species is not unlike O. arenarium, forming, as it does, a tuft of narrow, entire, dark grey-green, bristly foliage, above which arise, to a height of one foot or more, erect or spreading, forked stems, terminating in elongated spikes of blooms, which open in succession from the base upwards.

O. helveticum, a European species, can hardly be termed striking, neither its inflorescences nor the colour of the flowers being conducive to a bright display, but it is a useful addition to the rather limited number of summer-flowering rock plants, and on this account might well be given a sunny spot on a cliff ledge, or in a crevice, requiring to be planted, like the other Onosmas, in well-drained, gritty, loamy soil.

ARENARIA LARICIFOLIA.

It is surprising that Arenaria (Alsine) laricifolia is not more often employed in rock gardens, if only as a carpeting subject for dwarf bulbs—Crocus species, etc.—for which purpose it is admirably adapted, forming, as it does, a close but not too dense mat of fine, rich green foliage.

It is quite attractive, also, when in flower, for it produces an abundance of dainty sprays of Cerastium-like blossom, clear white, lightly and delicately veined with green, the whole forming a sheet of soft whiteness during the height of summer.

A. laricifolia occurs abundantly throughout the granitic formations of the Alps, and in rock gardens asks no more than a sunny position and light, stony soil, through which its long tap roots may penetrate to become lost in the lower levels. *M. W.*

VIOLA ALANNAH.

It is not uncommon that longer acquaintance with certain plants leads one to revise estimates of their value. There are some which fail to retain the high opinion held of them at first, and there are others, again, which have proved their value to such a degree that they rise several points in our estimation, and often render themselves indispensable. In this latter category I have placed the little hybrid Viola called Alannah. It originated, I believe, at Lissadell, and is understood to have been derived from V. bosniaca and V. gracilis.

When I acquired it first I considered its purple flowers rather dull, although relieved by the small yellow eye. I find, however, that its colour grows upon one and that V. Alannah is such a cheerful little plant, and such a splendid and obliging grower, that it is taking a high place in my garden where I have now many plants of it. It is of even dwarfer habit than such hybrids of V. gracilis, as Lady Crisp and Purple Robe, while it soon forms a large, spreading mass. It is so easy to propagate, by means of pieces pulled off with a root or two attached, that there is no reason why it should not be plentiful in any garden. It is a true perennial and very hardy, as was shown by its behaviour here during the past winter. *S. Arnott.*

HARDY FLOWER BORDER.

DRACOCEPHALUM NUTANS.

There are several species of Dracocephalum now in cultivation, and grown with varying degrees of success, notable among them being D. Forrestii, D. Isabellae and D. Ruyschianum, while previously included in the genus was Physostegia virginiana which, with its variety speciosa, is not infrequently met with in herbaceous borders.

It is surprising, however, that Dracocephalum nutans, from northern Asia, is not grown more extensively, as it is well worth a place either in the front of the herbaceous border, or on the rock garden, for it is a good perennial, is of bushy habit, and does not exceed one foot in height. The flowers are produced freely during the latter part of June and early July in densely-whorled, nodding racemes, the bright rich blue corollas and purple-tinted calyces producing a rich display of colouring.

D. nutans presents no difficulties in the matter of cultivation, its requirements being a warm and sunny situation and moderately light, well-drained soil, but it is advisable to guard against excessive moisture at the roots during winter.

LYTHRUM VIRGATUM.

It is only during comparatively recent years that the Willow Herbs have received recognition as garden plants, but now they are firmly established as both border and waterside plants, for which latter purpose they are specially adapted.

Lythrum Salicaria, our native Willow Herb, is familiar to everyone, being commonly met with adorning the banks of streams and other moist places, and there are now several forms of it which are distinct improvements on the type and are first-class herbaceous plants.

L. virgatum, the subject of this note, is not so robust and vigorous in growth as L. Salicaria, and is of such graceful charm that no garden should be without it. Although it is generally recommended as a waterside plant, such a position is not essential to its well being, for it will flourish in the ordinary well-made herbaceous border to which it will add distinction during the summer months.

This species is a native of Europe and northern Asia, and is stated to have been introduced to Kew in 1776, by Jacquin. It is figured in the *Botanical Magazine*, t. 1,003.

Free in growth, but not rampant, nor given to encroaching upon its neighbours, L. virgatum forms an elegant, bushy plant up to three feet high, its slender, branching growths being clothed with lanceolate leaves and terminated by charming spikes of bright, rosy-purple flowers, the whole plant, when in bloom, presenting a very bright and attractive appearance.

A very showy variety of this species, which is fast achieving popularity as a border or waterside plant, is that known as Rose Queen, which possesses the gracefulness of habit of the type, and has long, rich, bright rose-coloured inflorescences.

L. virgatum is one of the easiest of hardy herbaceous perennials to grow, flourishing in a deeply worked and well enriched border, and it may be increased very easily by division.

NEPETA MACRANTHA.

While Nepeta Mussinii is grown almost universally, and deservedly so, in gardens, it is not generally realised that there are other members of this genus which are highly attractive border plants, such a species being Nepeta macrantha, a native of Siberia and a good perennial. True, it is perhaps rather coarse for the small border, but in large herbaceous borders or in a sunny position in the wild garden, it will prove a delightful and showy subject. The drawback is its scent, which to some people is disagreeable; Wildenow, for instance, likened it to rancid oil.

It makes a dense, bushy mass of growths two-and-a-half to three feet high, its stems being furnished with short-stalked leaves, varying in shape from cordate to ovate-lanceolate, and green on both surfaces. The slender-tubed, rich lavender-blue flowers, each about one-and-a-quarter-inch long, are produced in whorls in the upper portions of the stems, so that when the plant is in full flower—during July—it is highly decorative.

N. macrantha, which is figured in the *Bot. Mag.*, t. 2,185, as Dracocephalum sibericum, is a good perennial, although in some gardens it would not appear always to be long-lived, and flourishes in ordinary garden soil, while it may be increased by division or by cuttings. *Kent.*

SOME SEDUMS.

Although many of the Sedums are not nearly so indifferent to drought as they are popularly supposed to be, several of them were remarkably bright and cheerful during the trying days of early July, when even Heaths like Erica stricta, four feet high, perished of drought. One of the most striking of these later-flowering Stonecrops is S. floriferum, which covered a square yard of a roasting border with its fresh green and two-inch cymes of golden-yellow blossoms. The flowering stems of this species do not rise above six inches and, the season being sunny, the colour effect is enriched by the reddening of the carpels. Even more pronounced in the development of this carpel colouring is the allied S. kamtschaticum, a more familiar species, which is taller than the preceding, but one, perhaps, not so effective for massing. S. Ellacombianum also belongs to this class, and it is not unlike S. floriferum in the tufted, dense growth of its vivid green foliage. The flowers are a clear yellow, produced in bold cymes, and prevail throughout July and August.

S. spurium in any good form is a very useful plant, ready to make the best of life and produce a bright show of colour under conditions that would try the temper of a House-leek. The crimson of the darkest kinds (var. splendens, for instance) is, perhaps, a trifle harsh, but some of the intermediate shades—rose, pink, pale lilac to white—are very attractive. A choicer plant is S. pulchellum, the moisture-loving, North American species, whose claw-shaped inflorescences, four or five inches across, are a beautiful rosy-purple. The linear leaves which crowd the low, sprawling growths of this fine Stonecrop are glaucous, the older ones often being tinted with the same colour as the flowers. S. pulchellum is worthily described by Dr. Lloyd Praeger as "one of the best Sedums in cultivation," but, even so, and despite its hardiness and ease of culture under proper conditions, it is not a common plant in gardens.

Some years ago, someone sent me a Sedum which I have only recently identified as S. monregalense. It may, quite likely, be something else—the race being so utterly confusing to anyone who is not a Praeger—but its very low growth, the four-whorled, oblanceolate, fleshy leaves, and the loose panicles of white, star-like flowers which terminate the hairy, four-inch stems in July, these and other features all point to that species. Moreover, this little plant has that marked preference for dampness and partial shade which the true S. monregalense is stated to possess, and which is an uncommon trait in Sedums. S. monregalense is stated to be a native of south-east France, Corsica and Italy, but the plant I have described is unquestionably hardy.

S. Praegerianum, which comes from Tibet, is a very distinct species, its prostrate summer growths radiating from the central rosette like the spokes of a wheel. These branch at the tips and, bearing large, egg-shaped flowers of a bright rosy-pink, surround the wheel with a ring of colour. This interesting species is hardy, but I have not yet found a spot quite to its liking. In a dry moraine it has succeeded tolerably well, but it is impatient of drought and seems to resent too fierce a sun. Near to this comes another Tibetan, S. primuloides, which makes a bushy little mound of dark green, obovate leaves in dense rosettes. The white, egg-shaped flowers, contracted at the mouth like those of a Heath, are borne in August in clusters of two or three. Although quite hardy, S. primuloides seems to suffer from excessive winter wet, but the fact that it is almost deciduous often makes it look more uncomfortable than it really is. I have it doing well in a pig-trough, with full exposure.

S. Anacampseros is always worth a place among plants of its kind for the sake of its neat rosettes of steely-blue foliage which is evergreen in mild districts, but its dull, purplish flowers are beyond hope, even in August. The allied S. Ewersii is a good plant for associating with such as the foregoing in a dry spot, the glaucous foliage being decidedly attractive. The flowers are a somewhat dull purple, but if they are not so handsome as those of the very similar S. Sieboldii, they do appear in August, whereas those of the latter often fail to show before October or even later. An unusual form of S. Ewersii came into my hands a year or so ago labelled "S. E. var. Ellacombianum." This is a beautiful plant, very vigorous and with larger leaves and taller growths than in the typical S. Ewersii. But the most notable distinction is in the flowering stems which, instead of consisting of a single umbel, as in the last-named species, have several lateral pedicels, two or three inches long, each terminating in a cyme of the bright purple flowers. If this description catches the eye of any authority on these things, perhaps he will tell me what the plant is.

S. oreganum and S. divergens, both worthy of being well-grown, so vivid is the rich golden-yellow of their flowers, will not be passed by at this season, for it is now that they assume their brilliant leaf-colour. Grown in a hot, sunny place and poor soil—if acid, so much the better—these Oregon species are often exceedingly brilliant, the fleshy leaves and branches developing bright shades of crimson and blood-red. S. Douglasii, the purple-leaved forms of S. spathulifolium, and S. Lydium are also among the kinds whose foliage becomes flushed with those ruddy, late-summer tints which contrast so strikingly with the cool, silvery-blue-greys and opal shades of other Stonecrops. *A. T. J.*

INDOOR PLANTS.

HYMENOCALLIS AMANCAES.

Nearly twenty years ago I was in Peru for the opening of a railway running from Lima to Ancon, and a special train was provided for the inauguration. About midway between these two towns, I noticed, from the window of my compartment, a single, yellow flower, growing on rising ground quite near the railway line. For the first and probably last time in my life, I pulled the communication cord, and the train was stopped by the engine driver with a sharp jerk, to the consternation of the officials. However, before they could make any enquiries, I was out of the train and running back to try to find the flower of which I had had a glimpse. This was not difficult, as it was standing well up above a mass of foliage, and I found that I had come upon half-an-acre or more of the Peruvian Daffodil, Hymenocallis (or Ismene) Amancaes.

The only plant in flower was the one I had seen, which was lucky, as I should probably not have stopped the train to examine the green leaves even if I had noticed them. The officials were by this time getting rather restive, as a formal reception had been arranged at the other end of the line, and we were already behind time; so I agreed to get back to my compartment if the spot was marked, and they promised to stop the train there on the way back, which was done! I had no digging tools with me, but the engine driver and stoker came to my help with shovels, and in a short time we had collected a nice lot of sound bulbs. These I took home with me, a long journey, via Chili and Argentina, but I managed to dry the bulbs slowly, and they arrived in good condition. I distributed a number to various friends, and tried some in the open in a warm border, but these latter were killed by the damp in the first winter. I still have one large pot of bulbs, and these have flowered regularly every year and increased slowly; this year they are better than ever and in every way stronger and more floriferous than any I have seen in their native land.

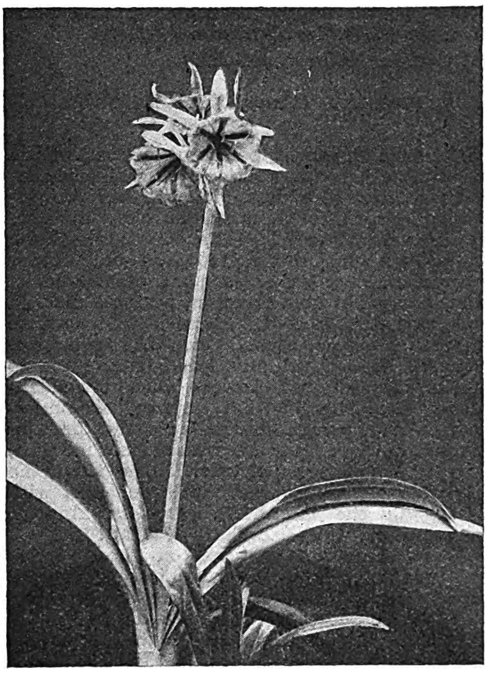

FIG. 52.—HYMENOCALLIS AMANCAES.

Fig. 52 shows the earliest plant with three, expanded flowers—there are four buds to follow on—which is, I think, a record, as, up to now, I have never had more than four to five flowers on a scape. The flowers are very sweetly scented, three inches across, yellow, striped with green, and the flat scape is over three feet high.

As with all Peruvian bulbs, Hymenocallis Amancaes must be kept quite dry during the resting season; when the leaves have died down I cover the pot with a sheet of glass and the plants receive no water until the new growth is two to three inches high in early summer; from then onwards the plants must receive increasing amounts until the flowers are over, when water must again be decreased. It should not be forgotten that in the coastal districts of Peru it hardly ever rains, the only moisture which vegetation ordinarily receives is from drizzles, heavy dews and mists; all plants from these parts and from the north of Chili must, therefore, be kept decidedly on the dry side, except when in full growth if they are to be grown successfully.

I have lately received consignments of other bulbous plants from Peru, but the only ones which have flowered up to now are Zephyranthes aurea, Z. carinata and Hippeastrum equestre. About the others I hope to report when they have flowered. *Albert Pam, Wormley Bury, Hertfordshire.*

CHRYSALIDOCARPUS LUTESCENS.

Unfortunately, the extensive collections of stove plants, which at one time were a feature in private establishments, are now but a memory. It is whispered, however, that interest in tropical exotics is reviving, and their cultivation rapidly extending.

The singularly graceful Palm, Chrysalidocarpus lutescens, was never at any time a common plant. Its general appearance, when young, resembles the better known Cocos Weddeliana, or Geonoma gracilis. The individual pinnae, however, are broader, and more widely spaced on the arching rachis. The most distinctive feature is the cluster of miniature plants growing at the base and feathering the main stem. These are not sucker-growths, as in the case of the Rhapis Palm, but spring from buds at the base of the main stem, as with Pandanus Veitchii, and, like Pandanus, the young plants may be detached with roots attached, and if carefully removed, and after being potted into small pots are plunged in bottom-heat in a propagating case, will eventually become established. Their removal detracts from the unique appearance of the parent plant, and only for purposes of increase is the operation advised.

The cultural requirements of this native of Mauritius are similar to those afforded other tropical Palms. Briefly stated, a rather close, warm, moist atmosphere during the growing season, with less moisture and a slightly lower temperature during the winter, are required. It grows well in a compost of fibrous loam, peat, leaf-mould and sharp sand, until it reaches specimen size, when, in common with the majority of Palms, a harder diet of fibrous loam with a dusting of bone-meal, suits it best. *Jonathan Fiona.*

ORCHID NOTES AND GLEANINGS.

COELOGYNE SPECIOSA.

Coelogyne speciosa is a very attractive Orchid. It has ovoid, four-angled pseudo-bulbs, one inch to two inches long, each bearing one thin, plicate, lanceolate leaf, which is about nine inches long. The flowers are produced singly or in pairs on a slender peduncle from the axil of the young leaf; each flower is about four inches in diameter. The sepals and petals are buff-coloured, the latter being much narrower than the sepals. The lip is large and very beautifully marked; the side lobes are erect, buff-coloured and thickly mottled with reddish-brown within; the front lobe is spreading, with two long, fimbriated keels running from the base, the tip and edge of the lip being olive-brown in colour. This species exhibits considerable variation, one form having a yellowish lip, with white edges.

C. speciosa is an epiphyte, and is a native of the Malay Peninsula, where it is found growing on trees in the dense jungle forests; it has also been found on rocks. When in flower, the temperature of the intermediate house should be found suitable for this species, but during the growing season it should be removed to the Cattleya house, or the growths may become stunted. The plants should be repotted or top-dressed so soon as the flowers are over, a compost consisting of equal parts Sphagnum-moss and fibrous peat, with the addition of a little silver sand, being most suitable.

In Malaya, the stems of Tree Ferns are sawn into lengths of from twelve to eighteen inches, and after the pith has been removed they are filled with a mixture of leaf soil, Sphagnum-moss and sand, in which plants of C. speciosa are grown successfully This species has a long flowering season in this country, commencing in April and continuing until July. *F. S. Banfield, F.L.S., Malaya.*

THE GENUS PRIMULA.

(*Continued from p.* 94).

PETROPHYES (Balf. f.). Plateau P. (Amethystina.)

This charming plant, which is possibly a sub-species of P. Virginis, produces a rosette of smooth, non-mealy leaves about one-and-a-half inch long, with leathery, glaucous, narrowly lance-shaped pointed blades, tapering into a membranous-winged stalk, dilated and sheathing at the base, about equalling the blade in length; margins edged with white cartilage and furnished with recurved, somewhat sharp teeth. Flower stem about three inches tall, dark purple, rough, minutely downy, bearing a one-sided umbel of three to five somewhat nodding, bright blue blossoms on slightly downy stalks about a quarter-of-an-inch long. Corolla concave, about three-eighths-of-an-inch across, divided into five small, rounded or oblong, entire or slightly notched lobes; tube about one-eighth-of-an-inch long, shorter than the calyx, with a small ring in the mouth.

Grows on the rocky plateau of Yo-Chow, in Hunan, at about 10,000 feet above sea-level.

Culture: As for P. amethystina.

PINNATIFIDA (Franch.). Feather-leaved P. (Muscarioides).

A beautiful species with a tuft of oval or oblong leaves from three-quarters- to one-and-a-quarter-inch long, and a half- to three-quarters-of-an-inch wide, wedge-shaped at the base, tapering to a narrowly-winged stalk equalling the blade in length; margins cut into square or oval lobes, which are again lobed like the fronds of the Male Fern; both surfaces thinly covered with fine white down, especially on the nerves and margins of the leaf. Flower stem two to nine inches tall, smooth below, mealy at the tip, bearing a head of numerous reflexed, fragrant blossoms, varying from deep rich purple to pale purplish-blue. Corolla about five-eighths-of-an-inch long and three-eighths-of-an-inch across, cup-shaped, divided into five oval, entire or obscurely notched lobes; tube cylindrical, three times as long as the calyx. Flowers in July and August. Introduced in 1908. *Gard. Chron.* Suppl. Illus., May 11, 1912.

Grows in damp pastures and among masses of shattered limestone, in peat, at 11,000 to 15,000 feet above sea-level, on the Lichiang range, in north-western Yunnan.

Culture: Grow it in rich, somewhat heavy loam, kept saturated when the plant is in growth, or in the bog garden, in peat. It is quite hardy.

PLATYCRANA (Craib.). Broad-headed P. (Denticulata.)

This rather attractive member of the Denticulata section has a rosette of leathery, broadly lance-shaped or oblong-lance-shaped leaves tapering to a broad, sheathed, reddish stalk, in all from three to five inches long; margins recurved, furnished with sharp, sub-regular teeth; upper surface very deeply nerved, underside covered with short, meal-producing, glandular hairs. Flower stem twelve to sixteen inches tall, stout, sparsely coated with white meal upwards, and bearing a head of lilac blossoms with a yellow eye. Corolla about five-eighths-of-an-inch across, with egg-shaped, bilobed or toothed segments; tube cylindrical, about half-an-inch long. Flowers in May. Introduced in 1917.

Grows in damp, alpine pastures in the Bhutan Himalayas.

Culture: As for P. denticulata.

PLEBEIA (Balf. f.). Plebeian P. (Petiolaris-Sonchifolia).

A dwarf, non-downy perennial species with a slender rootstock and a tuft of membranous leaves from two to three inches long, with elliptic or oblong-elliptic or sub-rotund blades, usually abruptly contracted into a wedge-shaped, scarcely winged stalk; margins edged with sharp, sinuate teeth; both surfaces covered with minute, meal-producing, glandular hairs. Flower stem about two inches tall, more or less dusted with meal and bearing an umbel of two to four rose-coloured blossoms on slender, erect stalks about three-eighths-of-an-inch long. Corolla concave, about five-eighths-of-an-inch across, with spreading, broadly heart-shaped or egg-shaped, very deeply-notched lobes; tube funnel-shaped, as long or slightly longer than the calyx.

Grows in the valley of Tsetshoupa, in Szechuan at about 8,700 feet above sea-level.

Culture: As for P. petiolaris.

POISSONII (Franch.). Poisson's P. (Candelabra.)

A beautiful, robust, perennial species, with a large tuft of smooth, non-mealy, rigid, somewhat leathery, more or less glaucous leaves, with oblong-lanceolate, blunt blades eight to nine inches long, tapering to a short, sheathing stalk; margins sharply toothed and folded upwards more or less on each side of the midrib, crisped and twisted; upper surface smooth, underside gland-dotted. Flower stem twenty to thirty inches tall, stout, smooth, bearing five to seven superposed umbels of from three to fifteen rose-coloured flowers with a golden-yellow eye. Corolla flat, about one-and-a-quarter inch across, divided into five broadly heart-shaped, notched lobes with toothed margins; tube funnel-shaped, slightly longer than the calyx, downy within, red inside and out, with a ring in the mouth. Flowers in August. Introduced in 1889. *Bot. Mag.*, t. 7,216.

Grows in damp pastures on the margins of forests in Yunnan, western China, at altitudes from 5,000 to 12,000 feet above sea-level.

Culture: Good fibrous loam and grit, in an open, but sheltered spot, with an abundant supply of water when the plant is in growth, and protection from severe frosts, are the conditions indicated. *A. W. Darnell.*

(*To be continued*).

THE CULTIVATION OF NEW ZEALAND PLANTS IN BRITAIN.*

(*Continued from p.* 93).

(c) Grown by Specialists.—By far the greater number of New Zealand plants in Britain are to be found only in public botanic gardens, such as Kew, Wisley and Edinburgh, or in the gardens of such enthusiasts as Major Dorrien Smith, Mr. Gerald Loder, Mr. F. W. Millard, Captain Simpson Hayward, etc., who take a special interest in them, and are continually importing them by all the means in their power. Edinburgh has been especially favoured, as many Otago botanists and gardeners, and others of Scots nationality, like Mr. Guthrie Smith, have sent thither plants and seeds in great quantities for many years past.

It would be hopeless to attempt here to give any idea of the wealth of our flora as represented in these specialists' gardens. I listed as many as two hundred species in one place. Naturally there is a good deal of reciprocity among the enthusiasts, and one sees the same plant, often a rare or unexpected one, again and again. For example, I saw in many different places, Veronica Catarractae (and varieties), V. Lyallii, V. Bidwillii, V. albicans, V. cassinioides, and many others. Epilobium nummularifolium, E. pedunculare, E. chloraefolium, Celmisia holosericea, C. Mackaui, C. densiflora, C. Lindsayi, Olearia cymbifolia, O. semidentata south and west only), O. moschata, Corokia Cotoneaster, Discaria Toumatou, Raoulia subsericea, Coprosma Petriei, C. Cunninghamii, C. parviflora, Helichrysum Selago, and H. bellidioides, Leptospermum scoparium and L. ericoides, Carmichaelia Enysii, Senecio Bidwillii, various species of Nothofagus, and so forth.

British gardeners have devoted a good deal of attention to the more promising of our plants and sought to improve them, with one very remarkable success or series of successes. Starting with the large-leaved Veronicas of various kinds, such as Veronica speciosa, V. macrocarpa, V. Lewisii, V. Dieffenbachii, V. salicifolia (and others—it would be impossible now to disentangle the strains involved) they have produced a large group of most beautiful and ornamental plants, some of which seem to be quite hardy, while others are as yet confined to the south and west. Some of them are doubtless well-known in New Zealand. The plants of this group have generally very large leaves and long spikes of handsome flowers with a great range of colour. Among the chief favourites are Blue Gem, Autumn Glory, Autumn Queen, Sargent, Splendour, Gloriosa, and one for which I got the name of "Gauntletii," but am not sure of the spelling. The colours range from pure white to deep purple, and some of them are extremely ornamental—I liked best a kind of salmon-pink variety which is very generally grown. In one nurseryman's list (from Penzance) the colours offered are pale lavender, deep blue, white, white and lavender, purple mauve, magenta, shaded red, tinted blue, brilliant red, magenta-purple and deep pink. I have seen some of these, flowering very late in the season, in Kensington Gardens, the Embankment Gardens, Chelsea Hospital Gardens and elsewhere in London, but the best and the greatest variety is found in the south and west.

Apart from this group there are a bewildering number of Veronica hybrids in most of the specialists' gardens. Some of these, such as V. Balfouriana and V. edinensis originated in Edinburgh, where one man (the creator of V. edinensis) specialised in this work. Others seem to be more or less accidental crosses, and these gardens are full of puzzles and of names which are unknown to the New Zealand flora. I hope that I was of some use to my various kind friends in correcting the inevitable mistakes in their nomenclature, but I was again and again completely baffled by the Veronicas which I saw and upon which I was asked for an opinion.

A most interesting cross has appeared at Tresco Abbey, where the common Cabbage Tree has hybridised with Cordyline Banksii, and the result is a very curious tree, large and handsome, with pendant leaves, combining the characters of the parents. Some of the Olearias and Pittosporums in Germany seemed to me to be probably hybrid. I saw one also very remarkable cross, the only one of its kind, I think, as yet recorded. This was in Mr. Ingwersen's garden near East Grinstead in Sussex. Here a plant of Epilobium chloraefolium (the very large-flowered form called by Dr. Cockayne E. kaikourense, I think) had crossed with one of the English wild species (E. roseum, probably), and the result was a very ornamental and pleasing plant, quite worthy of being followed up.

The hybrid Leptospermums produced by the Rev. A. Boscawen, of Ludgvan, Cornwall, are quite celebrated, the best known of these being the variety which bears his name. Unfortunately, these were not flowering when I visited this garden.

A hybrid Corokia, C. virgata, is grown at Kew.

TREES AND SHRUBS.

LONICERA SPLENDIDA.

A specimen of this rare Honeysuckle sent me by a generous Cornish correspondent a couple of years ago, came through last winter without the slightest injury. It is a robust grower, putting forth slender shoots several feet in length, so long, indeed, that it does not look like being much of a success on the eight-feet wall which it has surmounted. In fact, it would probably have scaled twice that height had not accidents occurred to its leading branches, which makes me think a pillar (or flag-staff) might prove a more suitable support. So far, this plant has maintained rather a thin, straggly habit. This, however, might be the result of the wall treatment, and it would be interesting to learn how it does under other conditions.

L. splendida, nevertheless, thoroughly deserves its specific name, for its foliage and the whole of the young wood is so glaucous that it might be dusted with a blue-grey meal. The upper pairs of leaves are completely united (connate) around the stem. My plant gave some blossoms this year about mid-July. The corollas, rather more than one-and-a-half-inch long, are lilac-tinted on the outside and yellow within. These flowers have a most delicious fragrance, the "drowsy syrups" of the common Honeysuckle clarified of their sultry sweetness to a degree of rarest refinement. It may be of interest to add that while a plant of L. ciliosa, growing within a few feet of L. splendida, was all last summer infested by white-fly (which has not re-appeared) the latter species remained untouched.

HYDRANGEA PETIOLARIS.

This climbing Hydrangea is a useful plant for quickly covering walls or old trees, to which it clings by aerial roots after the manner of Ivy. It is a deciduous species, a native of Japan, and the glossy, Apple-green, heart-shaped leaves make a highly attractive covering, especially as they turn a vivid yellow before falling in autumn. The flowers are not particularly striking, being small and greenish-white, but the broad corymbs are adorned by a few pure white bracts of sterile blossoms at the margins.

H. petiolaris is extraordinarily vigorous and rapid in growth. A plant put in at the base of an old, leaning Alder a few years ago has now grown twenty-five feet in height, completely enveloping the trunk of its supporting tree. But H. petiolaris is so adaptable that it may be used for covering rocky banks, and it makes a distinctly attractive mound planted as a bush in the open with a few stumps to ramble over. *A. T. J.*

CRATAEGUS CARRIEREI.

A fine stem, a sturdy conical shape, dark green foliage, and many fruits in November (retained throughout the winter) are a few outstanding merits of Crataegus Carrierei (C. Lavallei). It is sparsely armed with long, stout thorns, and it seldom reaches more than twenty feet in height. The leaves are downy beneath, obovate or oval, and coarsely toothed, The corymbs of large, white flowers are produced in great quantity in June, and these give place to the countless fruits, which are spotted with brown. They begin to colour before the leaves fall in December, from pale yellow to orange-scarlet, and persist until the spring.

As Mr. Bean states, this Thorn is believed to be either a seedling variation of C. stipulacea (differing from this by the globose fruit having a Pear-shaped base and being richer in colour), or a hybrid between C. punctata and C. Crus-galli. Although the subject of these notes has dotted fruits reminiscent of C. punctata, and they remain on the tree, as do those of C. Crus-galli, both these supposed parents are more glabrous than C. Carrierei.

Being of neat habit and small stature, it is suitable for most gardens, and is generally grown as a standard. *Graham S. Thomas, Cambridge.*

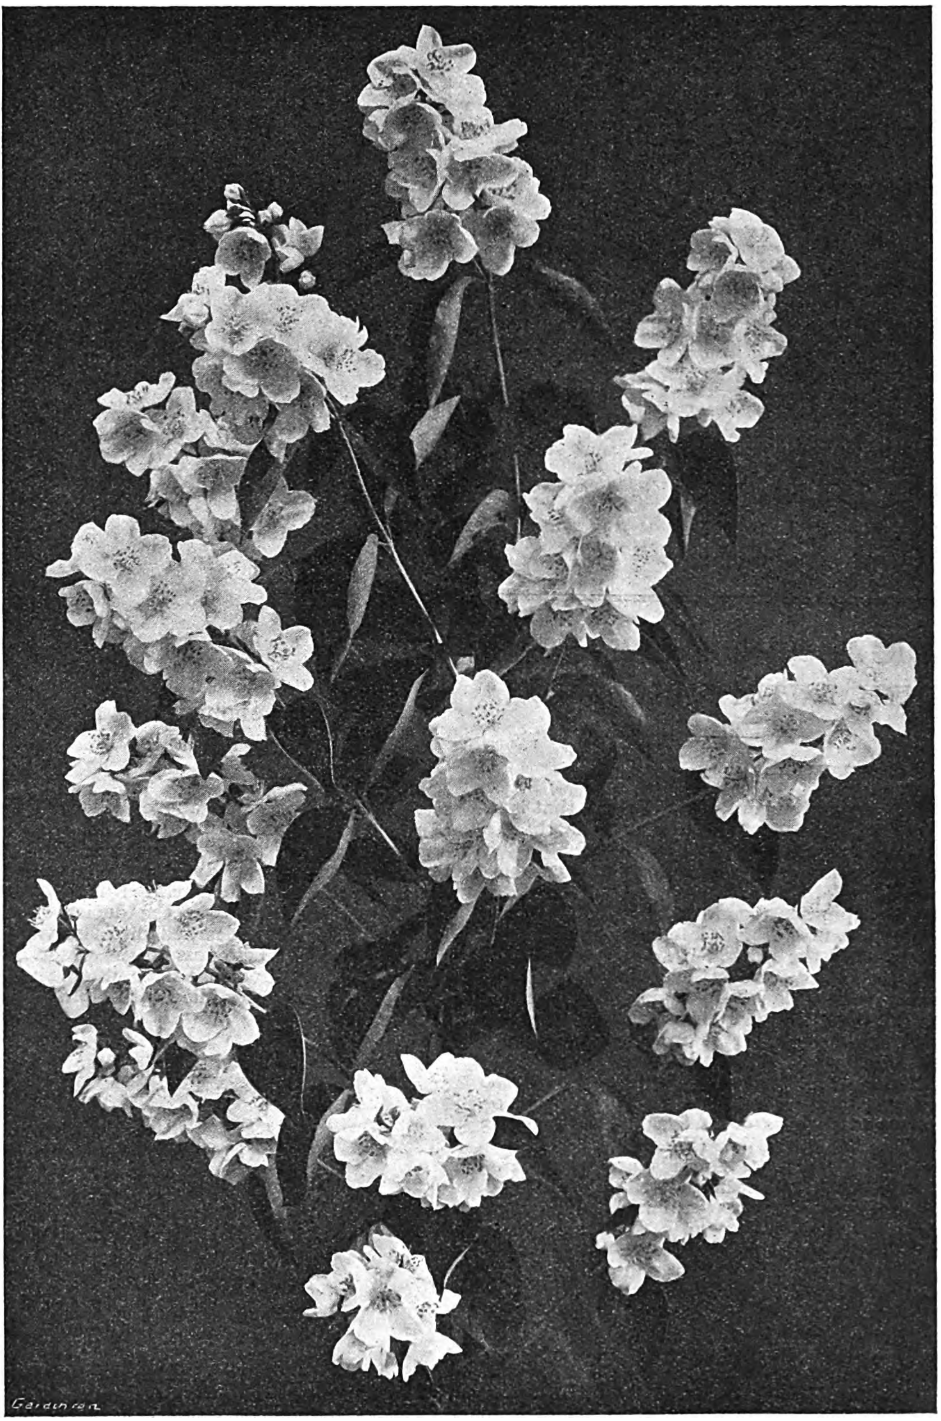

FIG. 53.—PHILADELPHUS INSIGNIS.

R.H.S. Award of Merit, July 16. Flowers white and fragrant. Shown by Mr. C. T. Musgrave.

(see p. 58.)

DESFONTAINIA SPINOSA.

Most lovers of shrubs will agree that this is a very desirable plant, and the difficulties attending its cultivation usually only add to the determination to succeed in making it thrive.

The greatest drawback in this respect is undoubtedly its slowness of growth—a specimen six or seven years old may not exceed a foot in height—and although we cannot materially hasten it, this shrub may at least be encouraged by good soil and a cool, moist position for its roots; partial shade also seems to assist. The other fault lies in the fact that it is not entirely hardy, although much more so than most people imagine; in districts subject to severe frosts it requires the shelter of a wall, while cutting east winds are also detrimental; near the coast it is perfectly happy in quite an open position. No doubt if conditions are to its liking, it will reach maturity earlier, but I have not seen a flowering specimen under thirty inches in height.

D. spinosa grows into a thick, upright bush, attaining perhaps to ten feet; the leaves are opposite, but otherwise closely resemble those of Holly, being dark, glossy green, with a waved and spiny margin. The flowers are funnel-shaped, about two inches in length, and half-an-inch across the mouth; in texture they are thick and waxy. The tube is a brilliant scarlet, and the mouth of the corolla deep butter-yellow, the two colours blending gradually, and forming a superb contrast to the shining foliage.

Desfontainia belongs to the Order Loganiaceae, and is a native of Valdivia and other parts of South America, whence it was introduced by the Messrs. Veitch about 1843. It is figured in the *Bot. Mag.*, t. 4,781. *B. O. M.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar, 7818.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XXVII.—AN ALPINE CAMP.

THE upper Temperate Rain Forest, that is to say, above 8,000 feet, is not exactly the place where one would look for Orchids, at least epiphytic species, despite their abundance in the jungle below. Small ground Orchids, often saprophytic, abound in the damp coolness of the forest, flowering in late summer and early autumn after the ground has been warmed up and well soaked. Nevertheless, two epiphytic species, which flower in June, are common, ascending to quite 10,000 feet. These are Coelogyne cristata, or it may be C. ocellata (Fig. 55), and a purple-flowered Pleione; the former growing in big clumps up in the trees, the latter usually solitary, growing on moss-covered rocks or in cushions of moss on the heavy laden Conifers (Fig. 57).

Above 10,000 feet, Orchids are more rare; yet it is here that the most striking are found, and three species of Cypripedium deserve notice. The first is the well-known C. tibeticum, whose big chocolate bags may be seen lolling on open, grassy slopes. With it is sometimes found a smaller species with a redder pouch and more brightly striped petals. Finally, growing with these two I found yet a third species, much smaller and daintier, about the size of C. guttatum, its little milk-white pouch neatly speckled with purple. The fine yellow-flowered C. luteum does not grow here.

Towards the end of the month of June, having made several trips into the alpine region, and desiring to climb still higher, we persuaded four Mishmis to carry loads up for us; more we could not get, so five days was the maximum time we could cater for. Bedding, a small alpine tent, drying paper, and food made up the bulk of the loads; and as our cook had to be left in charge of the main camp we had to cook for ourselves. June 30 was actually a fine day, the coolies arrived in camp that evening, and on July 1 we started up the ridge in sunny weather. A camping site was selected on the ridge just above the last Fir trees, at an altitude of about 12,000 feet, and the coolies having dumped down their loads, departed, leaving us to our own devices. We pitched the tent over a carpet of dwarf Rhododendrons, and Buttercup took over the duties of cook. But first we had to descend into the valley a few hundred feet below us to get water. This valley, a mere basin on the slope, where the snow lingered late, was now filled with alpine flowers, the most abundant being a maroon-red Nomocharis, which grew in hundreds on the rubble mounds, with an egg-yellow Lloydia, and a blue Corydalis; two species of Anemone, one with purple the other with cream flowers; and the Gamboge Primula which sheeted the grassy slopes. On some of the earth banks such as were not already swamped with these flowers, I found a tiny 'Soldanelloid' Primula. These gems are too delicate and rarefied for our gardens, even if they would grow there, which they will not; but they are ever a joy to the botanist. Our wee plant, barely an inch-and-a-half high, carried one, or two, rarely three, pale violet bells on its thread-like stems, and recalled two species collected in the Seinghku valley in 1926, Cherry Bell (P. silaensis) and Blue Microbe (P. fea). The latter, however, is a rock plant, and Cherry Bell has flowers of quite a different colour, so I conclude that the Kaso 'Soldanelloid' is a new species.

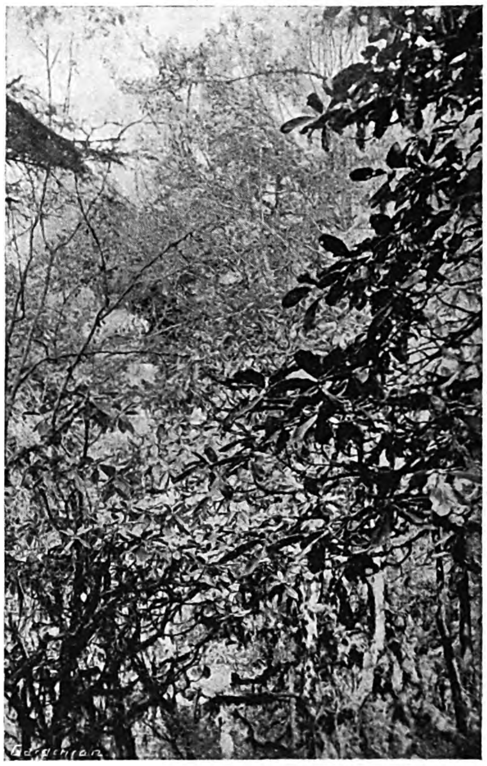

FIG. 54.—RHODODENDRON FOREST.

9,000 feet altitude.

The afternoon was now far spent and the sky completely overcast. It was time to prepare for the night, so having filled the petrol can with water, we started up the steep slope, alternately carrying this awkward 20 lb. load. We had almost reached the top when disaster overtook us. Exhausted with barging through a tangle of Rhododendron scrub, I set down the can on the steep face; it slipped, and toppled over. For a few seconds I watched it, fascinated, as though paralysed with horror, while trying to regain my breath. Before I could put out a hand to save it, the heavy tin was rolling, jumping, plunging down the slope! We caught one glimpse of the scarlet missile flying through the air in an immense final bound, and then it was lost to sight and sound. We rushed down the slope, although I felt convinced that our only water can had taken the valley in its stride and was lost evermore in the main, thousands of feet below; probably it would hit a tree and explode. Imagine my joyful surprise, therefore, when I found it lying on its side buried in the basin of flowers, not far from where we had drawn our water! It was much battered and bruised, leaking, too, but not irreparably damaged. So we lugged it up the hill once more, and this time reached camp without mishap. By this time it was raining. An hour was spent trying to light a fire, but at dusk we gave it up, crept into our tent, ate a cold sardine, and went to bed.

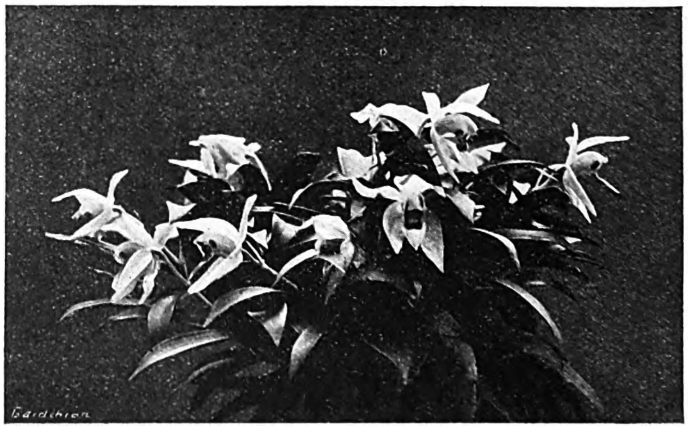

FIG. 55.—COELOGYNE OCELLATA (?).

10,000 feet altitude.

The next three days were much alike, fine first thing in the morning, wet the rest of the day. I explored the ridge so far as the foot of the final precipice, where there was still a lot of snow lying, and descended into the gullies on either side. We seemed to be quite a month too early for the high alpine flowers, other than Rhododendrons and Primulas. The former were nearly all over. On the high turf slopes, tussocks of R. campylogynum were just coming into flower, and another similar species with pink flowers was in bloom. On the rocks a prostrate 'Anthropogon' with wiry stems and tight heads of large, pale pink flowers was breathing its last, and the blood-red rivulets of R. repens had cooled off like slag. A few heaps of the

ROSE FLAMINGO.

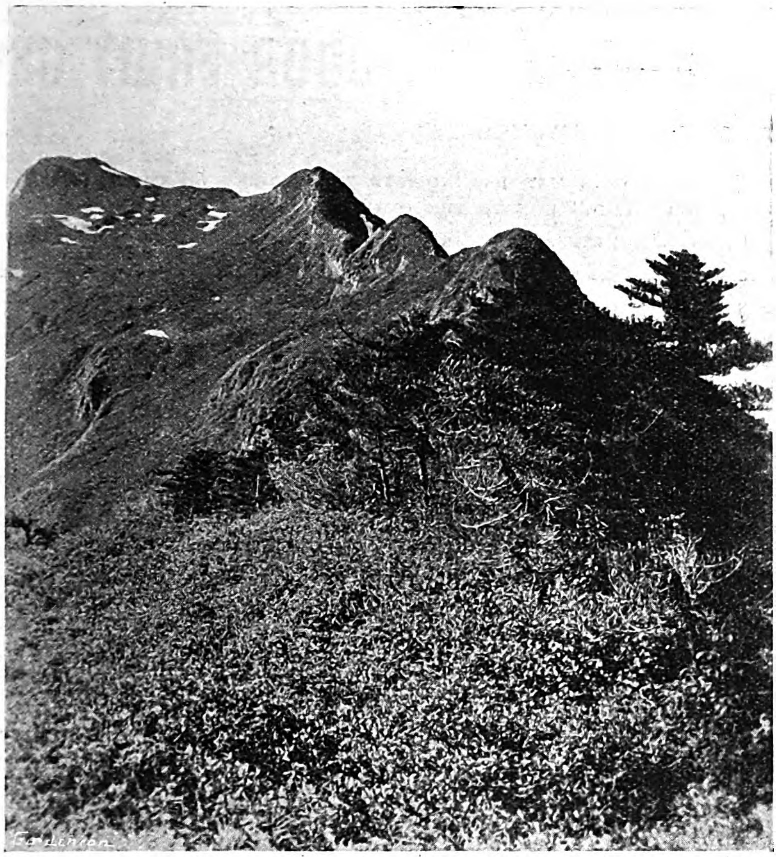

FIG. 56.—KASO RIDGE, WHERE MR. F. KINGDON WARD AT LAST REACHED THE ALPS.

Rhododendron scrub and Abies Webbiana in foreground.

purple 'Saluenense' still smouldered through the smoking mist, and the 'Brachyanthum' was not yet finally extinguished. But by far the most beautiful of all, even with the dew of death on its brow, was 'Rose of Kaso'; except that its flowers are shell-pink, in habit and foliage it matches the superb 'Carmelita' (Tibet, 1924). I shall have more to say about these creeping and crouching 'Sanguineums' later.

As for Primulas, the blue 'Muscarioid' was common on the precipitous turf slopes which it shared with the dwarf Iris; P. calthifolia, now a big, leafy herb, was still in bloom, its pallid, candle-light yellow almost extinguished in the golden blaze of the Gamboge Primula whose ground it shared in part; and the lighter yellow 'Nivalis' which cropped up here and there among hassocks of Rhododendrons, was practically finished. I almost despaired of finding a Meconopsis, but at last I spied a solitary, prickly Poppy in bud, no doubt M. impedita, although I never saw another one, and cannot confirm this. The very next day, however, I discovered none other than M. paniculata, a species not hitherto known to occur outside Sikkim or Nepal. There was no mistaking the four-petalled, sulphur-yellow flowers arranged in axillary cymes all up the four-foot leafy stem, rising like Aphrodite from its sea-green ring of foliage, or the orange anthers, and latex; it might conceivably be a variety, or a local form, but it was M. paniculata at heart, right enough. I could hardly have been more pleased with this discovery had it been an entirely new species.

On the whole, then, our bag was not as good as we had expected, or at least hoped for, and there is little else to record, except a Caltha with purple or, as some might say, magenta flowers, a purple-flowered Morina, a Cremanthodium, a Gentian, a few dwarf Cruciferae, Diplarche multiflora and a few other species common to all the mountain ranges in this part of Asia. As remarked elsewhere, most of the ground was covered with a dense scrub or carpet of Rhododendron, and where that failed, it was either bare rock or still under snow; but, although the variety of alpines was not great, certain species, such as the 'Narcissiflora' Anemone, yellow Lloydia, red Nomocharis, and Gamboge Primula, occurred in incredible numbers. August would, no doubt, bring forth a new crop altogether.

Apart from botanical excursions, our four days and nights were passed chaotically huddled in the tiny tent, amid wet plants and paper, cooking frugal meals of soup and Rice in a steady downpour over a fire which smoked evilly. On July 5, we got up as usual at dawn, put on our wet clothes—we could get nothing dried, of course—had breakfast, packed up our things, and sat waiting miserably for the coolies. It poured with rain all the time, and at 4 o'clock, no coolies having appeared and our food being finished, we strapped on our rucksacks, and leaving everything on the hill, marched down to camp, where we arrived at 7 o'clock. The coolies, who had come up from the village the same afternoon, daunted by the deluge, stayed at the lower camp instead of coming up to bring us down. We had no bedding, but managed to pass a fairly comfortable night. If possible, July 6 was even worse than the previous day, but the Mishmis went up and brought our loads in.

Two Rhododendrons were now flowering finely in the forest. One, a fragrant, white-flowered bush, was clearly allied to R. crassum; it is the latest of all the forest Rhododendrons. The other, with little, fiery-orange, tubular flowers, almost insignificant were they not borne in such numbers, suggested R. Keysii. The individual flowers are, as hinted above, quite small, and each truss has only about three flowers; but the trusses, instead of being terminal as is usual, are axillary, and the leaves being crowded at the ends of the shoots, the effect is that of a red-hot mass of flowers.

The rain continued, and our supplies being now exhausted after six weeks in this camp, we called up the Mishmis and on July 10 returned to the village below. *F. Kingdon Ward.*

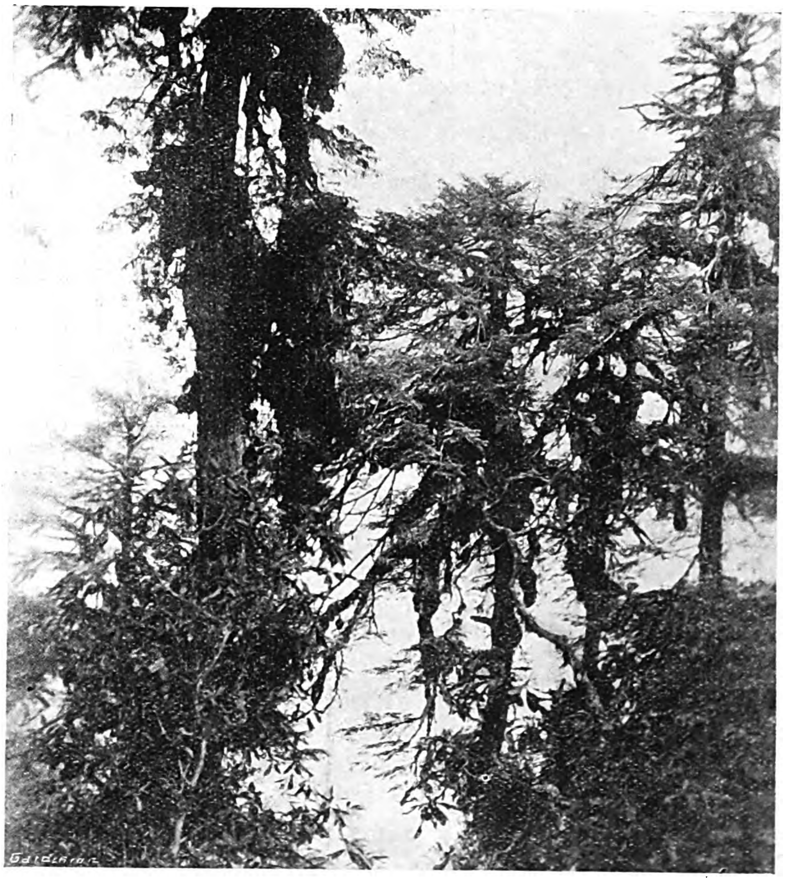

FIG. 57.—TSUGA TREES ENVELOPED IN MOSS.

REPORT ON THE CONDITION OF THE OUT-DOOR FRUIT CROPS.

[FROM OUR OWN CORRESPONDENTS.]

THE WORDS "AVERAGE," "OVER," OR "UNDER," AS THE CASE MAY BE, INDICATE THE AMOUNT OF THE CROP; AND "GOOD," "VERY GOOD," OR "BAD," DENOTE THE QUALITY.

FULLER COMMENTS WILL BE GIVEN IN THE FOLLOWING NUMBERS. SEE ALSO LEADING ARTICLE ON PAGE 101.

FRUIT REGISTER.

PEAR CLAPP'S FAVOURITE.

Clapp's Favourite is quite a useful Pear for the latter part of August—there are not many to choose from—being of good texture and flavour when at its best. But to get it in that condition it needs watching almost as closely as a Williams's Bon Chrêtien. It is a robust, upright grower, and its handsome fruits will often average fully half-a-pound in weight. It thrives equally well in any form or on either stock.

This Pear has a short season, and it is better to gather the fruits a little too early than wait until they begin to change colour, by which time their best quality is already over. In any case, the fruits keep only a few days.

It is not so early coming into bearing as some, and is only a moderate cropper with me, and although such an early-fruiting variety, it is one of the last to come into flower. Its scarlet-striped fruits and large, shining foliage make it one of the most decorative varieties as a specimen bush near the lawn. This Pear was raised in Massachusetts and named after the raiser.

PEAR DOYENNÉ D'ETÉ.

This is almost the first of the hard fruits to mature, being ready by the end of July in some seasons, and lasting in various soils and positions until the end of August or even later.

It has the smallest fruits of any good Pear, and these often hang on the branches as thickly as Gooseberries, but it needs a suitable variety near it for cross-pollenation to induce such fertility. The most fertile tree I ever had was a standard with the old Bergamot Pear worked on the top. It makes a good tree in any form and on either stock, but one does not want a standard of an early variety. The fruits should be picked before they begin to turn yellowish-green, as they become mealy if allowed to hang too long; they are best eaten straight from the tree; they are very juicy and sweet at their best, with a very distinct and peculiar flavour.

The season of this Pear may be extended to nearly a month by making the first picking from the sunny side of the tree rather early, even before the fruits have reached their full size. Pear Doyenné d'Eté is one of the earliest to come into flower and the blossom is not too hardy. It is a very old variety and is stated to have originated with the Capuchin monks, a couple of centuries ago.

APPLE JAMES GRIEVE.

This handsome Apple has achieved popularity very quickly, and this is not to be wondered at for it is a good and early bearer of fruits of excellent quality, and makes a handsome upright bush with large and rather shining leaves. The fruits seem almost better, both in appearance and quality, in a cool or damp summer than in a hot or dry one, perhaps because Scotland is its native country.

It is of quite common occurrence to see fruits in the market early in September, but for private purposes they are better left on the tree until the middle of the month at least, gathering the most mature fruits as required from then until the end of the month. Some consider the fruits are better eaten straight from the tree, but although they may lose in harshness and sharpness of flavour—a recommendation to some—they gain in richness of flavour by being kept a few days.

Complaints have been made of the fruits rotting while on the tree and of premature falling, but this is apparently a matter of exceptional soil or climate.

Like some other early varieties of Apple it is one of the latest coming into flower. It has a tendency to form fruit buds at the tips of the shorter growths of the current season, which must be borne in mind when pruning. Well-grown fruits of this Apple should average four to the pound. *A. Petts.*

HOME CORRESPONDENCE.

Geranium Pylzowianum.—Mr. Arnott's note (p. 47) on Geranium Pylzowianum has interested me. G. Pylzowianum, as I have always known it, fits the description given both by Mr. Arnott and Farrer, the flowers being much nearer a soft, clear rose than magenta. The ground colour of those of G. lancastriense at its best very nearly matches it in tint. But some time ago a correspondent sent me a plant which, while its running, mat-forming habit of growth and general appearance suggest G. Pylzowianum, it departs very widely from that species in other peculiarities. That is to say, its tallest leaves rise to a height of ten or twelve inches, and they are a very full-toned, mottled, cucumber-green, the tips of the lobes being bronzed and the stalks a rich, deep crimson. The flowers, which appeared in June, were somewhat larger than those of G. Pylzowianum, and they were a very dark crimson-purple. I would not call them magenta (even the " morning after "), but they were almost the exact colour of those of that form of G. argenteum which is many shades more intensely crimson-purple than the type. Can any reader enlighten me as to what this is ? *A. T. J.*

Cyclamens in a Cottage Window—I am sending you a photograph of two Cyclamens (Fig. 51, p. 105), grown by a cottager near here, in his little cottage window. These Cyclamens have been in the same pots (seven-inch) for five years without any repotting. The corms are almost as large as the pots. The plants are kept in the window until the foliage has died down, and then the pots are laid on their sides in an out-house, to be brought back to the window again when growth recommences. I was invited to go and see these plants some time ago, and found one had seventy blooms and numerous buds, and one had sixty blooms and lots of buds. I thought this note might be of interest to my fellow craftsmen. *E. Snelgrove, The Gardens, Roundway Park, Devizes.*

FOREIGN CORRESPONDENCE.

ASTRAGALUS SINICUS.

The note by Mr. T. Hay, in your issue of May 4 (p. 327), on the genus Astragalus (A. utahensis) interested me much. A Chinese species called A. sinicus, which is widely cultivated and naturalised in Japan is, I believe, worthy to be included among " desirable species." It is of prostrate habit, with odd, pinnate leaves, with usually from seven to nine green, obovate leaflets. The flower stems are four to six inches tall, each bearing an umbel of five to eight flowers of rose-purple shade. As a Japanese proverb says, " Don't take Rengeso (the Japanese Milk Vetch) in your hand; but leave her as she is in the field " ; this most floriferous Leguminous plant is extremely beautiful when carpeted or massed in the field. The Japanese call it Genge, or Rengeso, and it is one of our most familiar plants in spring. It is extensively cultivated as a fodder plant or for green manure in Japan, and also in the United States and other countries for the same purposes, but is not so well known in the horticultural world. There are meritorious agricultural and horticultural varieties. One of the former attains the height of nine feet, while one of the latter only attains a few inches. By spreading Leguminous bacteria on the soil when the seeds are sown, the crop is increased considerably. This method is practised, and pure cultures of bacteria are sold in Japan. Taking back the soil where A. sinicus had been grown, to their own country, before the great war, from Japan, some Germans succeeded in growing Astragalus sinicus perfectly. In this way some Japanese alpine Leguminous plants, which I heard complained of while I was in England, might be grown successfully.

If Mr. C. T. Musgrave and Mr. T. Hay care to have the seeds and bacteria or soil, I will be only too glad to send some. Just now, the beginning of June, the plant has finished its long flowering period. *K. Yashiroda, Japan.*

SOCIETIES.

NEWCASTLE HORTICULTURAL.

The annual excursion of the Newcastle-on-Tyne Horticultural Society took place on Saturday, July 27, when the famous gardens of J. C. Straker, Esq., were visited by one hundred-and-five members.

The party was met by Mr. Alex. Hay, gardener, and conducted through the fruit houses, where Grapes, Peaches, Figs and Melons of the highest quality were seen. The terrace garden is a feature of the place and here the Delphiniums, climbing Roses and other plants were splendid.

The pot Chrysanthemums were carefully examined by the enthusiasts as Mr. Hay hopes to retain the Henderson Cup won by him at the Newcastle Chrysanthemum Show last November.

An extensive wild garden where Primulas were seen in their thousands was next visited ; the rock garden was full of interesting plants, and the time was all too short to see everything.

Vegetables and outdoor fruits were of show quality, and the bed of Onions was admired quite as much as the house of well-grown Carnations. Over two hours were spent in strolling around the grounds before the party proceeded to Hexham. Mr. G. W. Patterson, Secretary, and Mr. John Dick, Chairman, who had charge of the arrangements, asked Mr. A. Hay to thank Mr. and Mrs. J. C. Straker for their kindness in opening their wonderful gardens to the members of the Society. Tea was served at Hexham, and then two hours were spent exploring the Abbey grounds and viewing the old-fashioned buildings and gardens. It was a record outing, and it is a good indication of the interest taken in the Society that no fewer than 105 members took advantage of the kind offer to visit Stagshaw Gardens.

GUILDFORD GARDENERS'.

A very enjoyable outing by members of this Association took place in mid-July, when a visit was paid to Sir Richard Garton's gardens, at Lythe Hill, Haslemere.

As the name suggests, Lythe Hill is situated in the hilly district of Surrey, and is just on the borders of Sussex, adjacent to Blackdown, made famous as the last home of Tennyson. The spacious mansion is of the Victorian period, built of red brick in striking contrast to the green verdure of summer all around. It is erected on the site of an older house, one wall of which, with a fine fresco of a tithe—or rent, collecting scene—still remains.

The mansion is situated on the escarpment of the hill commanding a delightful and extensive view across the Weald, embracing part of Surrey and part of Sussex. Far away are the North Downs, with Leith Hill above Dorking on the horizon, and richly timbered undulations between wherein are Hiscomb Hill and Highdon Boll—both famous beauty spots, and in this situation of many natural charms the beauties of nature have been supplemented by the art of man and the place made still more beautiful.

Across the lawn in front of the house is a grassy declivity known as the American garden, where Rhododendrons in some 360 varieties flower in season, together with many shrubs such as Kalmia latifolia; Deodora Cedars, and Cypress, tall green columns eighty feet high, also flourish here amid massed beds of Ericas. Near the house is a small rock garden around a Lily pool, beyond which is a cluster of Hydrangeas with blue flowers growing naturally. Near at hand is a small glade, in perfect contour, where is Lawsonia erecta var. viridis, and where a solitary crane resents the intrusion of strangers. The background is of Cypresses, Palms and shrubs. From the glade the ground drops sharply for some three hundred yards, and on this slope a new rock garden has just been made. Upwards of five hundred tons of stone have been brought from Cheddar and placed in position so as to appear like a natural formation. The rock garden broadens and deepens as it descends and is split up into a number of channels down which water falls and gathers into a pool at the bottom. The water is first pumped from a spring about a mile away and has to be raised 250 feet. Passing from the top to the bottom, it was observed that already many plants have found a congenial home. Funkia Sieboldii was in bloom by the water's edge, and Foxgloves in variety were flowering higher up the banks; Crinodendron Hookeri, with charming, rose-coloured, pendant blooms, was noted, also Mimulus Brilliant, Astilbe Ceres, Astilbe Betsy Cuperus, Astilbe Thunbergii var. Moeheimi, Primula Bulleyana, Meconopsis cambrica var. flore pleno, and many Irises in various colours. Planting is still going on, but it must be some time before the work is completed, and longer still for the full beauty to mature.

On the hillside, as a setting to this wonderful rock garden, are numbers of Oaks, Spruce, Cypress and other trees indigenous to a woodland dell; but the most striking is the grouping of several clumps of slender Beech trees, five or six in a group, that tower tall and straight like the clustered columns in a vast cathedral. In other parts of the garden are herbaceous borders, spacious and well-kept; Rose pergolas, resplendent with well-known ramblers at their best, and immense rows of Sweet Peas which of themselves added glory to the garden.

In the glasshouses were well-grown specimens of Trachelium coeruleum, double Petunias, Gloxinias, Streptocarpus, Begonias, Crassulas, Coleus, Celosias and a particularly attractive plant in Amaranthus tricolor. Grapes and Tomatos are also grown in perfection and abundance.

The kitchen garden was in keeping with all the rest, but apart from a very fine crop of Boskoop Giant, among the Black Currants, space does not admit of a detailed account.

The whole establishment testifies to a garden-lover as its owner, and reflects great credit upon the gardener, Mr. E. S. Hayes, and his staff.

Sir Richard Garton kindly provided tea for the visitors at the Swan Hotel, Haslemere.

PAPWORTH AND EVERARD HORTICULTURAL.

Friends of Mr. H. G. Shaw, late of Bryn Lupus, Llandudno, and now gardener to A. J. Thornhill, Esq., Diddington Hall, Buckden, Huntingdonshire, will be interested to hear of his recent successes at the above show.

He was awarded the Dr. Varrier-Jones Silver Challenge Cup for the best display of flowers in the show; this display covered an area of fifteen feet by five feet by five feet, and was composed entirely of Sweet Peas in eighteen distinct varieties. The quality of the seven exhibits in this class was extremely good, but Mr. Shaw's Sweet Peas were of outstanding merit.

Mr. Shaw also won three first and one second prizes at the above show, and also had the honour of being presented with the Challenge Cup by H.R.H. The Duchess of York, who highly complimented him on his great achievement.

On the following day at Huntingdon, Mr. Shaw was again a very successful exhibitor of Sweet Peas.

FALKIRK AND DISTRICT ROSE.

The Annual Show of Roses, Sweet Peas, Carnations and Violas, under the auspices of this Society, which was held in the Town Hall on July 27, proved to be the most successful in its history. So numerous and extensive were the exhibits that space had to be provided in the entrance hall for the Pansy and Viola classes. Competition generally was keen and in all sections the quality of the blooms was above the average standard.

In the open section for Roses, Messrs. D. and W. Croll, Dundee, staged the best collection of cut blooms arranged in a six-foot space, in which the prominent varieties were Betty Uprichard, Lady Inchiquin, Mrs. Henry Morse, Lady Roundway, Ivy May and Etoile de Holland. The class for six baskets was well filled, and the highest honours were awarded to Mr. R. C. Ferguson, Dunfermline, whose specimens of Mrs. C. Lamplough, Dr. A. Carnegie, Mabel Morse, Mrs. George Marriott and Frau Karl Druschki were outstanding. Messrs. D. and W. Croll were second with younger and lighter blooms, and the third prize went to Messrs. Thomas Smith and Son. So far as size and quality were concerned, there were no Roses in the show to compare to the first prize lot of twenty-four blooms in eighteen varieties exhibited by Messrs. Adam and Craigmile, Aberdeen. In a uniformly good collection, Dr. Deacon, Anne, Margaret McGredy and Dr. I. Petyt stood out prominently, while the bloom of Mrs. Henry Morse was chosen as the best Rose in the show. The Aberdeen firm also excelled with twelve blooms of H.T.'s.

In the class for twelve crimson Roses, Messrs. Smith and Messrs. Austin and McAslan, Glasgow, were placed first and second, respectively, with well-grown blooms of John Russell, while in the class for twelve blooms, of white or cream varieties, all the competitors with one exception exhibited Mrs. Charles Lamplough; the prize-winners were: First, Messrs. D. and W. Croll; second, Mr. A. Taylor, Larbert; and third, Messrs. Smith and Son.

The exhibits in the gardeners' and amateurs' section testified to good cultivation, and here the principal prize-winners were Mr. F. Wheeler, Tayport; Mr. James Boyd, Falkirk; Mr. D. Montgomery, Bainsford; and Mr. J. Braithwate, Linlithgow.

Messrs. Torrance and Hopkins, Busby, were successful in the class for eighteen vases and six vases of Sweet Peas; while Mr. J. R. Paterson, Alloa, who scored in the class for twelve vases, also secured the special award for the best vase in the show, with Royal Pink.

The honours in the Pansy and Viola competition were shared by Mr. Hugh McCall Linlithgow, and Mr. Henry Robertson, Kelty; while the first prize awards in the Carnation classes were secured by Messrs. Torrance and Hopkins, Mr. James Smith, Darvel, and Mr. J. McFarlane, Airdrie.

Messrs. Dobbie and Co. exhibited a large collection of Roses, representing popular varieties, while Messrs. Austin and McAslan featured newer varieties and novelties.

ANSWERS TO CORRESPONDENTS.

Broad Beans Unhealthy.—*W. F. A.* The Broad Bean plants were found to be free from pathogenic organisms. There was some sign of root damage by either wireworms or millipedes. The plants appeared to be suffering from "blindness," the contributory causes of which are many. Information regarding the state of the plants should be communicated to the seedsman from whom the seeds were purchased.

Cyclamens Starved.—*C. A.* The Cyclamens plant shows no sign of having been attacked by either insects or fungi. The symptoms are those of starvation. The soil submitted for examination is deficient in nitrates and phosphates. Repot the plants in a richer compost, using fresh loam.

Grapes Shanked and Scalded.—*F. C.* If all your Grapes are as badly affected as those sent for inspection, no treatment of any kind will save the crop this year. The Grapes are suffering from shanking, scalding and from a very bad attack of mildew, caused by imperfect ventilation, while other daily details regarding watering and damping have been neglected. It is impossible to secure good Grapes by attending to the vines one day and leaving them to themselves the next. See reply to *A. L. B.*, in *The Gardeners' Chronicle* of July 20.

Intermediate Stocks.—*C. B.* You have sought advice much too late regarding Intermediate Stocks to flower during the months of December and January. To flower them at the period named the seeds should have been sown in April. By sowing the seeds now you could obtain good flowering plants by the end of March. The seeds should be sown in light, open soil and germinated in a cool greenhouse, so soon as the seedlings can be handled they should be pricked off into small pots and grown under cool conditions, finally potting them into forty-eight-sized pots, when this is necessary. Any ordinary potting soil is suitable, provided plenty of lime-rubble is used. It is practically impossible to flower Sweet Peas and Calendulas at the season named, as being hardy they will not withstand forcing. However, seeds may be sown in the autumn and the plants grown under cool conditions to produce flowers during early spring.

Melons Failing.—*E. A. A.* The two Melons were so badly smashed when received that we can only surmise what may be the cause of your trouble. The Melon is one of the easiest of all fruits to grow, up to a certain point; the critical time comes when the fruits being to ripen, as then, unless the cultivation has been correct, the plants and fruits collapse. The chief causes of failure are over-watering with cold water, over feeding at too late a stage in an endeavour to enlarge the size of the fruits, and allowing the bottom-heat to fall too low at the finish. Bottom-heat should always be brisk and steady especially near the finishing period, and tepid water only in reduced quantities should be used.

Names of Plants.—*J. P. O'D.* 1, Eryngium alpinum; 2, Lomaria magellanica; 3, Lastrea felix mas grandiceps.—*E. A. H. K.* Sparaxis tricolor.

Pear Growths Diseased.—*W. F.* The Pear shoots have been heavily infested with green-fly, Aphis pomi. It is too late to remedy the matter now, but the affected tree should be sprayed thoroughly in January with an approved tar-distillate spray at seven per cent. If some of the eggs are missed during winter spraying, the aphides will be detected on the young shoots in May, when they should be forcibly sprayed with a nicotine-soap wash.

Poplar Leaves Spotted.—*A. and M.* The Poplar (?) leaves are attacked by a Septoria leaf-spot fungus. Collect and burn all fallen leaves and spray the trees, if this is practicable, in May, with Bordeaux mixture.

Sweet Peas with "Streak."—*A. R.* The Sweet Pea plants are attacked by the bacterium, Bacillus lathyri, commonly known as "streak" disease, which is induced by an excess of nitrogenous manures. Water the plants at weekly intervals with sulphate of potash (one ounce to five gallons of water) using one pint to each plant until the new growth is observed to grow away clean. The disease may be spread by the pruning knife, so it is wise to wipe the knife, after cutting infected plants, on a rag soaked in two per cent. Lysol.

Tomatos Falling.—*T. O.* It is somewhat difficult to give a reason for Tomatos falling before reaching maturity. In the first place you state you have a good crop of fruits, but no mention is made of the health of the plants. We note you have planted 700 plants in a house eighty-six feet by thirty-nine feet. This, in our estimation, is rather overcrowding, and the trouble may be partly due to this and to insufficient moisture at the roots. If this is the case the foliage would fall an easy prey to mildew, which would cause the fruits to fall before they are fully matured. The trouble may, of course, be due to faulty root action caused through some check in the early stages of growth. We have known Tomatos cast their fruits when potash has been used in excess.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 61·3°.

ACTUAL TEMPERATURE—
The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, August 14, 10 a.m. (Greenwich time). Bar. 30·2. Temp. 68°. Weather, fine.

The Drought.

THE drought which recent rains have mitigated, if not ended, has played strange pranks in the garden and country. Thanks to it, large tracts of the countryside have appeared seared and brown twice within six months: first, as the result of the severe winter, and now in consequence of the not less severe drought. So also in the gardens, the shortage of water has revealed to those who take all good things for granted, that the glory of the garden abideth not in words . . . but in lawns. Robbed of their setting of verdure all manner of beautiful garden things have failed to exercise their full powers of seduction, and the whole garden has put on its end-of-the-season Augustine look long before August was come. Lucky in such a season are those who possess supplies of water from rivers or deep wells in sufficient abundance to admit of all the watering being done that the garden needs. Lucky, certainly, but unless laid out on irrigation lines, what a labour! How to satisfy an earth so thirsty, when sandy soil behaves like a sieve and clays expose gaping cracks down which the water would pour uselessly unless the hoe were used first to stop them! The drought has been so capricious in its incidence that generalities are more than ordinarily dangerous. As an example of that caprice there was the storm of rain in June soon after Ascot, which bestowed three inches of water on the Maidenhead district and left Oxford without a drop. Again, in Yorkshire, anyone who motors northward through the county will find the grass land south of Scarborough all burned up and brown, whereas northward, albeit that the farmers are no less clamant of the sorrows of the drought, the fields are still green, although, of course, very short of grass. Yet, in spite of the all but complete absence of rain which has afflicted some districts throughout the present year, the gardens, even in these districts, have withstood the scarcity remarkably well. There was, perhaps, never a season when plants have flowered more freely. Exceptions there have been, of course, but writing generally, it has been, and still is, a wonderful year for blossom. Those who rely on bedding out have, of course, suffered severely, unless watering has been possible. Tall varieties of Antirrhinums bedded out in late spring look as though they were Tom Thumb varieties—so dwarf are they. Nor is that the only effect of water shortage upon them, for in despite of their minute size they are full of flower buds and must be pinched back if they are to make good specimens when rain releases them from the arrest of drought. Yet more pathetic than the bedded out plants are the wall plants. In normal seasons the gardener who has dry walls can produce effects which those who garden in flat places may admire but cannot emulate; but in dry seasons, even although the hose be plied with assiduity, the plants suffer terribly. To see a Sempervivum wilt is indeed a rare sight, yet common enough this year. Worse even than the present damage to plants grown in wall and rock gardens where water is not available, is the prospective damage due to the failure of supplies of plants for future years; for the first garden precept of the rock or wall gardener is that which used to be always on the lips of the late Reverend H. J. Bidder, of St. John's College, Oxford. Towering above the novice, he was wont to say: "If you would succeed as a rock gardener, learn and master the art of propagating plants." This year, with growth arrested, save where water has been plentiful, the normal time for that work is passing, and there is nothing to propagate. How wise, judged by this event, is the gardener who keeps a large reserve of rock and alpine plants in the propagating yard which, composed of narrow, sandy beds, should be attached to every garden. These beds at least can be kept watered and they will supply generously cuttings and layers and divisions to make good the inevitable losses of this memorably dry year. Needless to say, in this reserve garden, besides the sandy beds, there should be a goodly supply of cloches and frames. The former will have proved invaluable in this sunny year; for, as is well known, cuttings rooted in sandy soil, soaked and kept soaked, covered with a cloche and exposed to full sunshine, root in half the time taken by cuttings planted in the open. So much remains to write about the effects of the unprecedented drought that we propose to discuss the matter again; in the meantime, we can but hope that any advice which it may be possible to give will not come too late to be of useful application in the present year.

Mr. Kingdon Ward's Plant Collections.—Under the title of *Field Notes of Rhododendrons and Other Plants collected by Kingdon Ward in* 1927-28 Mr. Lionel de Rothschild has prepared a very interesting and descriptive list of discoveries made by this well-known traveller, chiefly in the Delei Valley in those years. No fewer than ninety-four Rhododendrons, many of them as yet unnamed, are listed in the nicely-bound little book which will form a useful companion to *Rhododendrons, their Names and Addresses*, compiled by E. H. Wilding in 1923. In addition to the Rhododendrons there is a list of Trees, Shrubs and Herbs collected during the same period. These make a total of ninety-seven and include several Primulas, Nomocharis, Violas, Roses and Gaultherias. Several blank pages are left for notes but we think that those who raised specimens of Mr. Kingdon Ward's discoveries would prefer to see this little book interleaved throughout.

Rural Water Supply.—The Minister of Agriculture and Fisheries announces that the Government has decided to make grants on the basis of thirty-three-and-one-third per cent. of the cost, to be increased to fifty per cent. if transferred labour is employed, in respect of approved schemes for water supply in rural areas serving groups of holdings. The dry weather during the past six months has emphasised the difficulties in regard to water supply in many parts of the countryside, and there is good reason to believe that rural water supply schemes could be carried out with great advantage to agriculture and to the improvement of the conditions of rural workers, at the same time contributing towards the relief of unemployment. Full details of the conditions governing these grants and those for field drainage, which were announced last week, will be published at a later date.

Richmond Allotments. — The Richmond (Surrey) Corporation is experiencing some difficulty in letting its allotments. In the Manor Road Allotments there are sixty-three vacant plots out of a total of one-hundred-and-seventy-three. There is a loss in rental of £161, and also the expense, estimated at £45, of keeping the vacant plots clear of weeds. Potential allotment holders in Richmond have insisted for some time that the rent of 52s. per ten-rod plot asked by the Town Council is too high, and now the Allotments Committee has been authorised to consider the whole question of allotment rents and report to the Council.

National Diploma in Horticulture and Teachers' Advanced Examination.—The Royal Horticultural Society's National Diploma in Horticulture has been awarded to the following, as a result of the written and practical examinations for the Diploma held this season:—Section 1 (General Horticulture): Mr. William George Fry, 111, Beverstone Road, Thornton Heath; Mr. Wilfred Charles Ibbett, 15, Burstow Road, Wimbledon, S.W.19; and Miss Florence Record, 9, Silverdale Road, Woodhey, Rock Ferry, Cheshire. Section 2 (Hardy Fruit Growing for Market): Mr. Robert John Garner, 3, Chapel Street, East Malling, Kent; and Mr. Robert Hart, Gorseland, Danbury, Essex. Section 5 (Landscape Gardening): Mr. Frederick Charles S. Robinson, 38, Broadway, Codsall, near Wolverhampton. The following have passed the Preliminary Diploma Examination and will be eligible to take the Final Examination after they have completed six years of practical experience in gardening:—Mr. Frederick Alexander Bush, Arddarroch Gardens, Garelochhead, Dumbartonshire; Mr. Leonard Frederick Clift, St. Patrick's Hall, Reading; Mr. Percy Cross, John Innes Horticultural Institution, Merton, S.W.; Mr. William Alfred Dove, R.H.S. Gardens, Wisley, Ripley, Surrey; Mr. Raymond John Gutsell, John Innes Horticultural Institution, Merton, S.W.; Mr. Alexander D. Harrison, 123 St. Helen's Road, Swansea; Mr. Leslie Philip Lee, 66, Selwyn Avenue, Kew Road, Richmond, Surrey; Mr. Norman Leech, 11, Royston Terrace, Goldenacre, Edinburgh; Mr. Brian Orson Mulligan, R.H.S. Gardens, Wisley, Ripley, Surrey; Miss Mary Page, 29, Queen Anne Avenue, Bromley, Kent; Mr. Maurice James Peters, R.H.S. Gardens, Wisley, Ripley, Surrey; Miss Lorna C. Style, Studley College, Studley, Warwickshire; and Mr. Ralph Edwin Thoday, St. John's College Gardens, Madingley Road, Cambridge. The Examiners report that many candidates again failed to reach the standard set for these examinations. This is especially true of the work done in the practical part. Too many were content with half-finished work, and more than that is expected of candidates with some years of garden experience behind them; others showed themselves very proficient in certain branches and very far behind in others. In the Preliminary, and in Section 1 of the Final, all-round proficiency in carrying out ordinary gardening operations is looked for, and the Board of Examiners wishes to impress upon candidates the importance of thorough mastery of the commoner and more generally called for operations so that they may perform them with ease and expedition. Merely to know how they should be done is not enough; in these examinations ability to do them counts for much more. They are examinations designed to see who are worthy to receive the highest professional Certificate the Society can bestow, the National Diploma in Horticulture, and the standard expected is naturally a high one. The Society's Certificate for the Teachers' Advanced Examination in School and Cottage Gardening has been awarded to Mr. Eric Clark, 294, Skellingthorpe Road, Lincoln; Mrs. Fearn, Hilltop, Millbrook, Stalybridge, Cheshire; and Mr. James R. McKnight, School House, Ilam, near Ashbourne, Derbyshire. One candidate failed. The Examiners report that the most noticeable feature of the candidates' work was the weakness in both description and performance of the practical soil operations, such as Full Trenching, Bastard Trenching and Ridging. Questions involving knowledge of the principles underlying horticultural practice were well answered, and so also were the compulsory questions of the written examination, although there was weakness shown by the failure of some candidates to prepare a cropping plan.

Campanula pyramidalis at Kew.—An extensive display of the Chimney Campanula in the Temperate House at Kew demonstrates the value of this hardy Bellflower for greenhouse and conservatory decoration. Grouped on either side of the long path right through the centre of the house, the position under the Tree Ferns provides ideal surroundings for displaying the beauty of these Campanulas. In all, there are about one hundred plants, ranging from about four feet to six feet in height, with flowers, mostly of blue shades but with a few examples of the white variety. The plants are rather more than two years' old from seeds, and are growing in nine-inch and ten-inch pots.

R.H.S. Scholarships, 1929.—The General Scholarship of £50 a year for two years, offered by the Worshipful Company of Gardeners, has been awarded to Mr. E. K. Lawrence, c/o R.H.S. Gardens, Wisley, Ripley, Surrey; and the Knott Scholarship of £30 a year for two years has been offered to Mr. John Hardy, Shadingfield, Beccles, Suffolk. These two scholarships are awarded on the results of a special examination designed to test the candidate's ability to profit by a course of instruction in horticulture.

Honour for M.M. Meunissier, Chenault and Petit.—Our friend and correspondent, M. A. Meunissier, of Verrieres-le-Buisson has been promoted Chevalier de la Legion d'Honneur; M. Leon Chenault, formerly of Olivet, near Orleans, who introduced many Asiatic and American plants to French horticulture; and M. A. Petit, Director of the Horticultural Research Laboratory at Versailles Horticultural College, have also been similarly honoured.

Glasgow Gardeners' Outing to Glenapp Castle Gardens.—On Saturday, August 3, a large number of members of the Glasgow and West of Scotland Horticultural Society took advantage of the arrangements made to visit Glenapp Castle Gardens, by the kind permission of Lord and Lady Inchcape. The weather was very unfavourable at the start, but cleared up before mid-day, and the sixty-mile run to Girvan was accomplished in good time. Here lunch was served at the King's Arms Hotel, and the party then proceeded by the rugged shore road to Ballantrae, reaching Glenapp policies about 3 p.m. Mr. Taylor, the gardener, and his staff were in readiness to welcome the visitors, and two pleasant hours were spent in admiring the well-kept gardens, each member finding something of interest among its many and varied features. The rock garden was first visited and its natural features favourably commented on, although at this season much of its glory had departed. In the glasshouses were magnificent crops of various fruits, all in prime condition, in preparation for the shooting season now close at hand, but the feature of the plants under glass was the excellent display of Carnations, from which it seemed difficult for some of the members to part. The flower garden and terraces were gay with all manner of summer-flowering plants. Roses added their beauty and fragrance, and the wild garden, with its waterfalls, was much admired, but while the masses of Primulas were now unfortunately over, they showed by their luxuriant foliage and numerous seed-pods how they revelled under the conditions provided. Above all, the tidiness and well-kept appearance was evidence of the care and energy of Mr. Taylor and his staff. Tea was served in the New Hall at Ballantrae, when Mr. Dagg, Past Chairman of the Directors (in the unavoidable absence of Mr. I. M. Fleming, the present Chairman), expressed the appreciation of the members for the great treat they had enjoyed, and called for a hearty vote of thanks to Lord and Lady Inchcape for so graciously granting permission to visit Glenapp. He also thanked Mr. Taylor for conducting the party, and for his great assistance in making arrangements. Mr. Taylor suitably replied, and the party then returned by way of the Stinchar Valley on the eighty miles run home, which was duly reached about 9.30 p.m. The thanks of the members were also given to Mr. J. Carrick Kerr, Secretary of the Society, for the splendid arrangements which enabled everyone thoroughly to enjoy the day's outing.

MR. SINZAEMON TANAKA.
(see p. 131.)

Legacy to a Gardener.—Mrs. Elizabeth Livingstone McLean, of Burfield Hall, Wymondham, Norfolk, who died on April 4, 1929, left £250 and a further £250 on his leaving her service, to her gardener, Mr. John Watt.

Agricultural Meteorology.—Some impression of the increasing importance of a knowledge of meteorology to horticulturists and agriculturists may be gathered from the fact that there will be an Agricultural Section of the Conference of Empire Meteorology, which is to take place in London, commencing on August 28. The Agricultural Section will meet in the Large Hall at the Civil Service Commission, Burlington Gardens, London, W.1, and will deal with (a) Collection of data for use in agricultural meteorological investigations and the extent to which uniformity is possible; (b) Opportunities for research in agricultural meteorology and methods that can be applied; (c) The use of meteorological data in the improvement of crop estimates and the supply of weather warnings to farmers. The preliminary arrangements for the meetings of the Agricultural Section are as follow:—Wednesday, August 28: Joint Sessions of General Conference and Agricultural Section; Seasonal Forecasting; General Climatology. Thursday, August 29: Morning—Historical Review, Plant Physiology and Meteorology, and Light and Growth; Afternoon—Fruit Production and Meteorology. Friday, August 30,: Morning—Climate and Animal Distribution, Weather and Insects, and Weather and Fungus Diseases of Plants; Afternoon, Use of Meteorological Data in the Improvement of Crop Estimates. Saturday, August 31: Visits to the Lord Wandsworth Agricultural College, Long Sutton; and to the Royal Horticultural Society's Gardens, Wisley, to inspect agricultural meteorological work. Monday, September 2: Visit to Rothamsted Experimental Station to inspect agricultural meteorological work.

Sandy Flower Show.—Although the function is of only one day's duration, the Sandy and District Floral and Horticultural Society invariably manages to arrange a great display on the occasion of its Annual Show. The date this year is Thursday, August 29, and the site, as usual, is Sandye Place, kindly lent by Mrs. Graves. In addition to hundreds of classes for poultry, dogs, rabbits, cats and pigeons, no fewer than two-hundred-and-forty-nine are provided in the horticultural section. The total value of the prizes offered at Sandy Show exceeds £2,000. The bands of the Scots Guards and the Coldstream Guards have been engaged to provide the music at this fifty-sixth annual show at Sandy, Bedfordshire. Entries close on August 19; the secretary is Mr. F. W. Western.

Ministry of Agriculture's Crop Returns.—In accordance with its usual practice, the Ministry of Agriculture has recently issued a report on the acreage of land in England and Wales under the various crops of economic importance, and it is interesting to note the fluctuations in the acreages of some of these crops. The total area under Beans, for instance, is 156,800 acres or 13,200 acres less than in 1928. This decrease, which is general except in Yorkshire and in the South-west, is entirely in Beans for harvesting as corn which are being grown on 143,900 acres, or 13,600 acres (8·6 per cent.) less than in 1928. The acreage of Beans picked green shows an increase of 400 acres, or 3·2 per cent. The total area of Peas in 132,400 acres, an increase of 18,400 acres compared with 1928. Peas for harvesting as corn occupy 78,600 acres, the remaining 53,800 acres being under Peas to be picked green, the increase as compared with 1928 being about 9,000 acres in each case. The area under Potatos is larger than in any year since 1922, the total acreage of 518,900 acres being 30,000 acres, or 6 per cent. higher than in 1928. Increased acreages were returned from the great majority of counties, the heaviest increases being in Lincolnshire, with 9,100 acres, Isle of Ely, with 4,400 acres, and Yorkshire, with 3,800 acres more than in 1928. The net increase in the area under root crops is due to an appreciable addition, amounting to 54,200 acres, in the acreage of Sugar Beet, which is 229,900 acres, or nearly 31 per cent. more than in 1928. This is the highest acreage yet recorded for this crop. The greater part of the increase is shown in the Eastern and North-eastern divisions, but the relatively heaviest increases were in the South-eastern and South-western divisions, which increased their 1928 acreages by over 50 and 100 per cent. respectively. The largest county increases are 12,300 acres in Norfolk; 10,000 acres in Lincolnshire; 8,000 acres in Suffolk; 5,000 acres in the Isle of Ely and 3,000 acres in Essex. Most vegetables are being grown on increased acreages, the most notable exceptions being Brussels Sprouts which show a reduction from 30,400 acres to 26,700 acres, and Celery, which shows a negligible drop from 5,800 acres to 5,700 acres. Cabbages for human consumption are being more widely grown in most counties, and show an increase from 27,900 acres to 32,400 acres. Cauliflowers and Broccoli have increased by 400 acres to 13,900 acres; Carrots by 300 acres to 10,300 acres; Rhubarb by 200 acres to 7,200 acres; and Onions by 700 acres to 2,400 acres, the increase in the acreage of Onions being over 40 per cent. The total acreage of orchard and small fruits remains about unchanged from that of last year, the acreage of orchards being 248,200 acres or 200 acres less, and that of small fruit being 64,900 acres, or 200 acres more than in 1928. The greatest changes in orchard acreages are reductions of 635 acres in Worcester, 307 acres in Hereford, and 329 acres in the Holland division of Lincolnshire. Kent, on the other hand, returned an increase in orchards of 995 acres. Variations in the acreage of the different kinds of small fruits were practically negligible. The Strawberry acreage at 20,400 acres is very slightly less than in 1928. Raspberries occupied 6,000 acres compared with 6,200 acres last year, while Currants and Gooseberries, at 34,800 acres, show a small increase. These crop reports were returned on June 4.

Professional Gardeners' Outings.—Numerous Yorkshire members of the Professional Gardeners' Association visited the Harrogate Public Parks and Gardens on a recent Saturday afternoon when they were the guests of the Corporation's Pleasure Grounds Committee. Under the guidance of Mr. J. E. Besant, the Parks Superintendent, visits were paid to Harlow Hill, the Valley Gardens, the Crescent Gardens and the Royal Hall Gardens. Mr. Besant was congratulated upon the fine displays he had provided and Councillor Pohlmann was thanked for entertaining the party. On July 22, the members paid a vist to the Gardens of Sir W. H. Aykroyd, at Grantley Hall, Ripon, where Mr. Ilott, the gardener acted as guide; the flower garden, Sweet Peas, herbaceous borders, kitchen garden, and glasshouses were inspected critically and greatly admired, while the rock garden, the collection of flowering trees and shrubs, the fine Conifers and the massive Yew hedges were sources of delight and wonder. Thanks were accorded to Sir W. H. Aykroyd and Mr. Ilott for their kindness and for the educational advantages the visit had provided.

Large Specimen of Rhododendron Falconeri.—Mr. Collingwood Ingram writes :—" The enclosed photograph (Fig. 58) taken at Kilmacurragh, Co. Wicklow, shows what is probably the finest specimen of Rhododendron Falconeri in Europe. It stands about twenty-three feet high and is as much, or more, through its broadest diameter. When the photograph was taken, early this summer, it was estimated that the plant carried over four hundred trusses of bloom."

A Plague of Toads.—The residents of Weston Mill, near Plymouth, are suffering a visitation of toads in such numbers as to constitute a serious nuisance. They attribute the undesirable number of toads, which even enter their houses, to a refuse tip which the Corporation has made in the district. It is said that the toads are much more in evidence during the mornings than at other times of the day.

Plum Crops in Worcestershire.—The Ministry of Agriculture and Fisheries has received further reports on the condition of the Plum crops in Worcestershire. The crop of Pershore Plums is stated to show marked variations not only between adjoining plantations but also between individual trees within the plantations, and this fact renders the estimation of the weight of the crop a matter of considerable difficulty. In the Evesham and Pershore district the Pershore Plum crop is reported to be of fair quality; the yield is estimated at approximately two tons per acre, which is considered by the reporters to be a light crop. In the Worcester and Stourport district, Pershore plums are reported to be of fair quality, but the yield is very light and is estimated at only about three-quarters-of-a-ton per acre, although possibly this figure may be exceeded in the area to the west of the Severn. Taking the area as a whole, it is estimated that there is a good average crop of coloured Plums.

Appointments for the Ensuing Week.—Wednesday, August 21: Eastbourne Horticultural Society's Exhibition; Bangor Horticultural Society's Exhibition (two days); Perthshire Exhibition (two days); Shrewsbury Show (two days). Thursday, August 22: Peebleshire Horticultural Society's Exhibition. Friday, August 23: Montrose Horticultural Society's Exhibition (two days). Saturday, August 24: Leeds Paxton Society's visit to Farnley Show.

" Gardeners' Chronicle " Seventy-five Years Ago.—*The Rice-Paper Plant.*—On the morning of April 20 last, the steamer in which I was a passenger dropped her anchor a little way up one of the rivers on the north-east part of Formosa. As this was my first visit to this fine island, and as I knew we had only a short time to stay, I lost no time in going on shore. Before leaving the vessel I had been examining with a spy-glass some large white flowers which grew on the banks and on the hill-sides, and I now went in that direction, in order to ascertain what they were. When I reached the spot where they were growing, they proved to be very fine specimens of Lilium japonicum—the largest and most vigorous I had ever seen. As I was admiring these beautiful Lilies, which were growing as wild as the Primroses in our woods in England, another plant of far more interest caught my eye. This was nothing less than the Rice-paper Plant—the species which produces the far-famed Rice-paper of China, named by Sir W. Hooker Aralia papyrifera. It was growing apparently wild; but the site may have been an old plantation, which was now overgrown with weeds and brushwood. The largest specimens which came under my notice were about five or six feet in height, and from six to eight inches in circumference at the base, but nearly of an equal thickness all up the stem. The stems, usually bare all the way up, were crowned at the top with a number of noble-looking palmate leaves, on long foot-stalks, which gave to the plant a very ornamental appearance. The under side of each leaf, its footstalk, and the top part of the stem, which was clasped by these stalks, was densely covered with down of a rich brown colour, which readily came off upon any substance with which it came in contact. I did not meet with any plant in flower during my rambles, but it is probable the plant flowers at a later period of the year. Numerous small plants were coming through the ground in various directions, which a Chinese soldier carefully dug up for me, and which are now safely deposited in Mr. Beale's garden at Shanghai. These, with a few samples of the largest stems I could find, will be sent to England in the course of a few months; the latter will prove an interesting addition to our museums of vegetable productions. The proportion of pith in these stems is very great, particularly near the top of vigorous growing ones, and it is from this pure white substance that the beautiful article erroneously called " Rice-paper " is prepared. The Chinese call this plant the *Tung-tsaou*. What it was, or to what part of the vegetable kingdom it belonged was long a mystery to botanists, who were oftentimes sadly misled by imaginary Chinese drawings, as some of those which have been published will clearly show, now that our knowledge has increased. Indeed the only drawing I have seen in Europe, which has any claim to be considered authentic, is that brought from China by Mr. Reeves many years ago, and which I have seen in the library of the Horticultural Society of London. *Robert Fortune. Gard. Chron., August* 19, 1854.

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN MOORE, Manchester.

Vanda teres.—Specimens of this sun-loving species, also of the hybrid Miss Joaquim, have been making a display of finely-coloured flowers for many weeks. The striking beauty of the flowers command universal admiration, and their beautiful rose colouring is retained well if the plants are shaded while in flower and given slightly drier and cooler conditions. After the blooms are removed, the plants should receive attention at the roots. Those stems that have lost their lower leaves and are rather leggy should have the lower portion cut away to a point that will allow the bottom leaves to rest on the top of the compost, which should consist chiefly of fresh Sphagnum-moss, with a little A.1. fibre intermixed. Ample drainage is necessary, and lumps of charcoal should be added to the compost. Where a large quantity is grown, beds may be made in Teak-wood boxes filled two-thirds with crocks, and the stems fixed in position with a neat stake, filling in firmly with the compost and charcoal, and finishing off with a layer of clean Sphagnum-moss. If so desired, several stems may be placed in well-drained pots, the stems being secured and the compost added as for boxes; this system is much the best if the plants are required for decorative purposes when in flower. Grow the plants in moist surroundings in the warmest house, shading the newly-potted specimens from direct sunshine until the roots are moving freely, when a gradual exposure to full sunshine should be allowed. Spray the plants and surroundings frequently, especially in bright weather, as when established, these Orchids revel in sun-heat and plenty of moisture, both in the atmosphere and at the roots, during the growing season. During the winter months, when the roots are not active, drier and cooler conditions, in the intermediate house, are required. When growth commences in the early spring they should be returned to the warmest house again.

Mexican Laelias.—These late autumn and winter-flowering Laelias have made good progress during the recent spell of bright weather. Plants of L. anceps and its varieties, together with L. Gouldiana, L. autumnalis and others, should be syringed during the morning and again early in the afternoon in favourable weather, although not so heavily as to fill the young growths with moisture, as these soon decay should a sudden change to dull weather conditions set in before they are dried out again; this is particularly the case with L. Gouldiana. If possible, the shading should be removed when the plants are syringed early in the afternoon, and the ventilators closed to induce a sharp rise in temperature, opening the ventilators again later in the evening to allow excessive moisture to disperse, and to keep the atmosphere sweet. A stuffy atmosphere should be avoided at all times. These Orchids revel in sun-heat, and abundance of fresh air and moisture during the growing season. Established plants that are now rooting and growing freely should be well inured to the sun so that shading may be dispensed with during August. During dull periods, the plants should be carefully examined for scale insects which often increase rapidly at this season, and quickly damage the new growths and leaves.

HARDY FRUIT GARDEN.

By HENRY H. COOK, Chief Assistant Lecturer, Reading University Horticultural College.

Peaches and Nectarines.—These will require constant attention in regard to moisture, the exposing of the fruits for extra colour and flavour, and the laying in and securing of successional shoots. There should be no lack of moisture at the roots now that the fruits are swelling, and liquid manure should be afforded to all trees carrying heavy crops. In this latter respect, however, the gardener must be guided by the vigour and general health of the tree. Liquid manure and other stimulants should be withheld from trees that tend to make gross wood, and a note should be made of these, to have them attended to during the late autumn. The cause of gross growth is always to be found at the roots, and, unless remedied, it is hopeless to expect such trees to set good crops of fruits. Peaches do not require a rich rooting medium, and if the soil is too rich, its rankness may be reduced by the liberal use of broken bricks and lime-rubble freely mixed with the staple soil, and firmed thoroughly by ramming. See that the fruits are not unduly shaded by the foliage, for those that lack colour are usually deficient in flavour also. This, however, should not be carried to extremes, for experience has proved to me that the fruits, while swelling, attain to large proportions when only slightly exposed, and, eventually, fully exposed for colour and flavour ten or twelve days prior to gathering. The continued hot and dry weather which we have experienced has brought the season of ripening much more forward than usual. In these circumstances it is advisable to examine the trees daily, and gather the most advanced fruits just before they are fully ripe. Not only is this necessary as a safeguard against insect pests damaging the ripening fruits, but a few days on a cool greenhouse shelf will greatly improve the flavour. The fruits should be laid in boxes lined with soft wood-wool, and shaded with tissue paper from strong sunlight. All extension and successional shoots should be neatly secured in their required positions, and while doing so, see that the older ties are not cutting into the wood; the soft bark, when once wounded by a tight ligature, seldom recovers from the disfigurement thus caused; besides, it is always a fruitful source of gumming. Trees that have been cleared of fruits should have the old fruiting wood and any superfluous growth removed, for this will assist in the proper ripening of the current season's shoots, which will be the fruiting ones of next year. The foliage should be given a thorough washing, and there is nothing better than a good soapy mixture to which has been added a little nicotine.

Aspect and Varieties.—Peaches and Nectarines may be grown successfully against walls in all aspects except northern, but a southern exposure is, undoubtedly, the best. An eastern exposure has the disadvantage, during blossoming time, of catching the early morning sun after a frost, thus rendering the blossoms useless. With efficient protection, however, in the use of fish-netting hung in front of the trees, this disadvantage may be overcome and an excellent set of fruits obtained. There is not the same danger when the trees are grown on south-east, south or south-west aspects, but it is advisable to take the same precautionary measures against frost during the blossoming period. The following varieties suitable for open wall culture can be recommended, and are arranged approximately in their order of ripening. Peaches: Waterloo, Hale's Early, Peregrine, Crimson Galande, Grosse Mignonne, Bellegarde, Lady Palmerston, Golden Eagle and Salwey. Nectarines: Early Rivers, Lord Napier, Darwin, River's Orange, Elruge, Pineapple, Dryden and Victoria.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Early Vineries.—Vines now cleared of their fruits should be copiously syringed late on fine days, a little soft soap and sulphur being added to the water if red spider has been troublesome. Inside borders which have been allowed to get rather dry should be restored at once to a moist, growing condition. If the vines are young and laterals are growing freely, applications of clear water may be good enough, but older vines, with but few laterals, will require more generous treatment, as there is a long period of summer weather before them, and diluted liquid manure may be given freely, and fresh stable litter may be placed over the surface of the beds to prevent evaporation. This mulch may be cleared away in the autumn to make room for the annual top-dressing. Laterals, having had full liberty, may now be checked by partial shortening. Attend carefully to outside borders, and if these are well-drained, do not be afraid of watering them with the hose for a few hours, as the roots should not suffer through lack of water at this stage. As each succession house is cleared of Grapes the vines should receive the same generous treatment with regard to root-watering and late syringing as advised for the early ones. Watch extra strong canes from which the maiden crop is expected next year; these may be improved by gradually reducing the laterals from the base upwards to the pruning bud. All the lateral growths above the pruning bud should be left, but keep the roots active until the vines go gradually and naturally to rest. Succession vineries containing ripe Grapes should be kept cool and airy, and possibly slightly shaded for a few hours on bright days, as black-fruited varieties soon loose colour. Borders and paths may be liberally damped during bright weather, but dull or wet weather will necessitate much drier treatment, and the maintenance of a very steady temperature, otherwise the fruits of varieties like Madresfield Court may crack. Muscat Grapes now ripe, or approaching that stage, should receive plenty of light by drawing the leaves and laterals a little aside, but not to the extent that the full force of the sun will strike the shoulders of the bunches. Sun-heat should now suffice, but in the event of a change to dull or wet weather, a little steady fire-heat will help to keep the fresh, warm air in motion.

Late Vineries.—Houses containing Grapes for autumn and winter use should be kept at a night temperature of 70°, and 80° to 85° by day, with a rise to 90° after closing with sun-heat and moisture. Plenty of good, warm, diluted liquid manure and an occasional dusting with vine manure, Guano or soot will assist the vines, as Muscats especially are gross feeders. If the weather continues steady and plenty of air can be given, scalding may not put in an appearance, as this may generally be prevented by keeping the house warm, with air admitted at night and free ventilation in the daytime; if this treatment is maintained for a fortnight, scalding will be prevented. The winter varieties will now derive great benefit from treatment as advised for Muscats, especially during fine summer weather. Also, like Muscats, they should be kept extra warm at night and the house ventilated freely through the day until the fruits have finished stoning. Lady Downes is most troublesome, but by keeping the berries dry and warm towards morning and allowing the day temperature to rise gradually, scalding may be prevented or reduced to a harmless form; Grapes always scald most under sudden alterations of temperature, when the weather is unsettled. A very little fire-heat will produce the desired effect at this time of the year, and while preventing condensation of moisture, it will increase the size and colour of the berries that double the amount of fire-heat will not give later in the autumn.

Cucumbers.—The weather throughout June and July having been bright and warm, Cucumbers have made rapid progress. Under such conditions their management has been extremely simple and, provided the plants are fed liberally, syringed well and cropped moderately, they will continue fruitful throughout the remainder of the summer. Keep the growths pinched at the first or second joint so soon as the fruits become visible, as waste of sap through bleeding is then prevented. A few old leaves and exhausted growths may be removed at each dressing, but this should not be carried to excess, as anything approaching a check after this date is detrimental to lasting and steady progress. Soft water, at a temperature of 85° to 90° should be used, and a steady bottom-heat of 75° to 80° maintained, light top-dressing of fresh, rough turf, lime rubble and bone-meal should be given frequently.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Hippeastrums.—Probably better known as Amaryllis, these will, by this date, have completed their growth, and so soon as this stage is reached, they should be removed to cold frames or, in any case, if allowed to remain in the house in which they have been growing, should be subjected to a lower temperature with an abundance of fresh air whenever the outside conditions permit, and water should be gradually withheld. Young, unflowered seedlings should not receive this treatment but should be kept growing steadily until they reach flowering size. Hippeastrum seedlings should now be ready for pricking off into pots or pans, and so soon as they are large enough they should be potted singly into small pots and kept growing in an intermediate temperature through the winter. Where seeds were later in ripening, do not hesitate to sow them at once, so that the young plants may be able to attain some size before the winter sets in.

Lachenalias.—If these plants have been treated as advised, they may now be taken down from the shelves where they have been well-baked by full exposure to the sun and the bulbs removed from the old compost and graded in their respective sizes. Large receptacles are not to be recommended for Lachenalias, four- or five-inch pots being most suitable. Place eight to ten of the largest-sized bulbs in a pot, in a compost of good, open loam and leaf-mould in equal parts, with plenty of sharp sand added. Where it is necessary to increase the stock the second-size bulbs may be grown on in boxes or pans to form flowering bulbs for another year. The newly potted bulbs should be placed in a cold frame, and should not be covered with any plunging material, such as is practised with other bulbs grown in pots. Water should be given sparingly during the early stages of growth, and they should be grown under the coolest conditions possible during all stages.

Calceolarias.—Prick off seedling Calceolarias so soon as they may be handled. The compost during their early stages of growth may consist of equal parts of sifted loam and leaf-mould, with plenty of sharp sand added. Place them in a cool house or frame, where they can enjoy plenty of light without being directly exposed to the sun's rays. Slugs are very fond of these plants, and should, therefore, be guarded against, or all one's labour will be lost in a single night.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

French Beans.—In addition to seeds being sown as advised in previous calendars, it will be necessary, where it is essential that a constant supply of French Beans be maintained as long as possible, to utilise empty frames for this purpose. The soil should be of a fairly light, loamy nature. Sow the seeds in rows about one foot apart, allowing nine inches between each seedling for development. It will not be necessary to put lights on the frames for several weeks, but give the plants plenty of light and air so as to encourage sturdy growth. Never allow them to become dry at the roots, and syringe the young plants overhead to keep them clean and in a moist condition.

Globe Artichokes.—Cut the heads of these immediately they are of suitable size and commencing to open. If not required at once, they may be stood in water, changing the water every day, and kept in a cool place until wanted.

Celery.—Dust the Celery plants now with soot as a preventive from attack by the Celery fly. If the pest appears, no time should be lost in applying the soot or spraying the plants with Bentley's insecticide, repeating the operation after an interval of two weeks to make certain that the fly has been checked, for once the larvae have settled in the leaves the crop will be checked and possibly ruined.

Herbs.—Any herbs which are to be dried for winter use may now be cut, choosing a dry day for the work, and tied up in bunches of medium size. Hang the bunches in a dry, airy shed to dry them thoroughly, and, later, remove them to the store-room, which should be kept perfectly dry.

Endive.—As Endive seedlings attain suitable size they should be transplanted into light, open soil, allowing eighteen inches between the rows and one foot from plant to plant. Further plantings of Lettuces may be made, preferably of black-seeded varieties, as these withstand the cold weather well.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Cistuses.—These are delightful shrubs for the large rock garden. The home of the genus is the Mediterranean regions and, unfortunately, none of the species is perfectly hardy; many did not pass through last winter successfully, and fresh stocks of these will have to be raised. All are easily propagated by seeds or cuttings. Some of the species produce seeds freely, but most of the hybrids are best raised from cuttings, which root freely if taken during August or early September and inserted in a cold frame or under a bell-glass. Cistuses do not transplant successfully from the open ground, therefore the cuttings should be potted on as they become rooted and kept growing in pots until required for placing in their permanent positions. Dry, sunny banks should be chosen for growing them, where they can have full advantage of all the light possible, yet be sheltered from high winds. Soil is an important factor; this should be of a light, sandy, well-drained medium; in such soils they will winter much more successfully. Planting should not take place until late spring; if planted during autumn and hard frost sets in, the plants may be crippled and never grow so freely as those planted in spring. Cistuses in general are not long-lived, therefore it is advisable to root a few cuttings each year to replace worn-out plants. C. cyprius and C. laurifolius are strong, robust-growing plants and longer-lived than the majority. C. purpureus is one of the best, making a fine symmetrical bush four feet high, and it is extremely attractive when covered with its reddish-purple flowers, with a deeper-coloured blotch at the base of each petal. C. crispus, a compact bushy species, is fairly hardy and will survive our average winters. C. Silver Pink is a real grand shrub, and has many good points to recommend it. The colour is a clear pink, the habit of the plant dwarf and bushy, and it has a decided advantage over many others in that it carries its flowers on stiff, erect stems; these blooms last well into the afternoon.

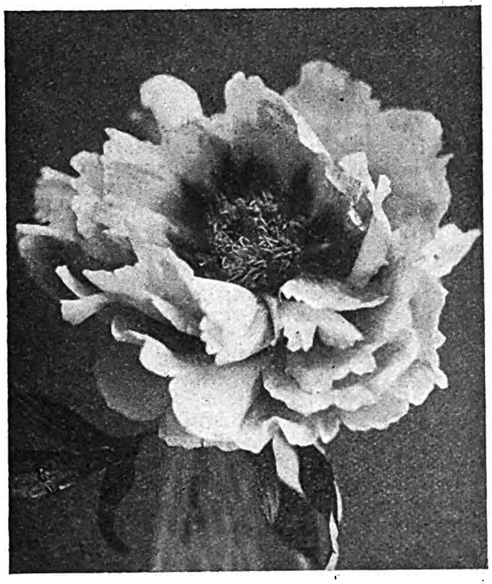

FIG. 59.—PAEONIA MOUTAN VAR. FUJISOME-KOROMO
(see p. 131.)

Narcissus Species.—The miniature species of Narcissi are charming companions to the Crocus species for pockets in the rock garden. N. Bulbocodium loves moisture and is never so happy as when placed near the bank of a stream or in moist meadowland. It will grow under the drier conditions, but the flowers will not be of full size. At Wisley it has naturalised itself freely in all manner of places, on dry parts of the alpine meadow, by the side of ditches and in the moist, peaty soil of the wild garden. Such a gem should be planted freely, in various places and encouraged to naturalise. Narcissus triandrus is an elegant and charming species, equally useful for sheltered nooks in the rock garden and in warm soils where the vegetation is not too strong; it will naturalise itself, flowering the second and third year from seeds. Another dainty species is N. cyclamineus, the first species to bloom. It loves a moist, peaty soil, and where such conditions do not exist, means should be found to prepare pockets of peaty soil for its reception. It does not seem to grow so freely in the grass as the former species, being more at home in the moist woodland, among moss.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Vegetables.—Where there is difficulty in wintering Parsley out-of-doors, steps should be taken to have a supply in frames, either planted in beds or in ordinary seed boxes, the latter being, perhaps, the better method, as they may be moved near the glass, or into a heated frame during spells of frost. Any ordinary soil containing leaf mould and some old lime rubble will suit this crop. Keep the frame close until the plants are established, after which open treatment is best so long as the weather permits. A sowing of Cauliflower seeds should be made in an early border to supply plants for pricking-off in frames for next spring. I have found Walcheren a good sort for this purpose, but Early London, All the Year Round, or any good variety should prove satisfactory. The soil of the seed bed, and later on in the frame, should not be rich, as a rather firm, short growth is best for over-wintering. Although it is a mistake to earth-up Celery too soon, no time should be lost when sufficient height and girth have been attained in attending to this, as growth is much freer and better after the first earthing. Where snails or slugs abound, dry soot and, or, flour of lime should be dusted on the plants and soil as the work proceeds. The plants and also the soil, should be dry at the time of earthing, and the stems should be carefully tied together. Press the soil gently around the stems before removing the ties.

Raspberries.—As the crop is cleared from Raspberries no time should be lost in removing the old canes and fixing a suitable number of new ones to the supports. In cases where the growth is left projecting above the wires, there is danger that it may be broken by wind; to avoid this bend such growths over temporarily and fix them near their points. No cutting back should be done at present, except of surplus canes, which should be cut back to the base.

Cinerarias and Primulas.—These are now growing freely and should not be allowed to dry out at the roots or suffer from lack of either root or top room, potting them on when necessary. A cool position is best for them, where little shading will be required. For Cinerarias, the compost, which should be used in a fairly rough state, may consist of three parts of loam, one of rough leaf mould, and one old cow or sheep manure, with sand and a little charcoal added. This will suit all kinds of Cinerarias, but for Primulas no animal manure should be used. A suitable mixture for these is two to three parts loam, one of leaf mould, and one of sand, lime-rubble and charcoal.

ALPINE GARDEN.

SENECIO ABROTANIFOLIUS.

The genus Senecio, in general, can hardly be associated with the rock garden, but as is usually the case, there is an exception, which in this instance is Senecio abrotanifolius, a valuable, early summer-flowering alpine plant from the Engadine and eastern ranges of the Alps.

The late Reginald Farrer, in his well-known work, *The English Rock Garden*, suggests that an association of this Composite with Campanula alpina, or C. rotundifolia, is very attractive, and he describes how that in the Engadine it is naturally associated with C. barbata, and such a colour combination—the flowers of S. abrotanifolius are a rich orange-yellow and quite one-and-a-half inches across—must be very effective and well worth reproducing in the rock garden.

This Senecio has finely-divided, glossy, dark green foliage, and when planted in a bed of stony, well-drained, light but moderately rich, loamy soil, to which some peat may be added with advantage, is not niggardly in the production of its inflorescences, which terminate the branched flower stems at a height of nine inches to one foot. S. abrotanifolius may be increased by seeds, which in good seasons, are produced quite freely, or by division. *M. W.*

TUNICA SAXIFRAGA.

As we approach autumn days we begin to prize more highly the flowers which linger in their opening, and are with us in the time when the rock garden is apt to become less bright and attractive. Some of these give us a foretaste of their beauty by flowering before summer has departed, and among these is Tunica Saxifraga, which even begins in June, at times, and favours us with a profusion of its little stars until, and even after, frost comes to despoil us of its latest flowers. This native of the Southern Alps, even to the Mediterranean, is perfectly hardy with us, and although in its native habits it seems to revel in the sunshine, it will even flourish with us in partial shade, although if we want to give such a precious little treasure its due we should plant it in the sunniest spots we have. When in flower it is a picture of elegance, the slender, graceful foliage being spangled over with little flowers, varying in different plants from pink to white and even in one case affording us double blooms, although these are less graceful than the single.

Tunica Saxifraga is very readily raised from seeds. Seedlings vary in colour, and the best should be chosen for retention and propagation by cuttings. This little plant soon forms a mound-like bush of loosely arranged branches which look almost too ethereal for the rude winds of late autumn but are yet unscathed by them. A light dry soil is favoured by Tunica Saxifraga, which has been in cultivation for many years.

CAMPANULA G. F. WILSON.

Dwarf Campanulas continue to retain their favour in most rock gardens of the present day, and no one can deny that this is justified by the charms displayed by the vast majority of these fascinating flowers. They are numerous, and the choice is very great, but among those I should not like to be without is that delightful hybrid named G. F. Wilson. Its beauty is undeniable and a good group gives us much delight as we view it in the rock garden. I am glad to see that it was appreciated by Farrer, who wrote of it as: "an important garden plant," and describes its chief features with much accuracy. It grows about six inches high, and produces a wealth of deep blue bells which are half erect, and open at the mouth. The charm of the colouring is enhanced by the paler tone of blue which shows itself towards the base of the bells, and which adds much to the charm when the flowers are examined more closely.

Although dwarf, it is a vigorous and easy grower, with rather grey, hairy leaves. It increases wonderfully rapidly at the root, without any tendency to being rampant, and I have here a large plant which has developed from a small piece put in two years ago. This is in a heavier soil than is afforded to other plants of Campanula G. F. Wilson; it seems to me that it flourishes in a heavier one than that generally provided for rock plants. It is said by Farrer to be sometimes called C. Valfourii, but I have never met with it under that name; it is also said to be quoted in some continental lists as Wilsonii. The parentage of this lovely little Campanula are understood to be C. pulla and C. turbinata. It has all the vigour of C. turbinata with a share of the grace of C. pulla. I consider that the plants should be allowed to grow to a good size, and one like that here blossoms so profusely that not a leaf can be seen through the mass of charming flowers. It is easily increased by division. *S. Arnott.*

BULB GARDEN.

LILIUM AURATUM.

The decorative value of this handsome Lily, whether grown as a pot plant or in the open border, is so well-known and acknowledged that it is not necessary to recommend it; but the object of this note is to record an extraordinary result from a system of cultivation in pots which is not universally practised. The system is that of growing these plants in pots from year to year without shaking out the bulbs and repotting, simply removing the top soil and top-dressing with new compost, and relying on intensive feeding to maintain vigour in the plant.

On a recent visit to Chadshunt Manor, Warwick, the residence of Colonel Stewart, I saw several dozen pots of L. auratum and L. speciosum grown under this system, and the gardener, Mr. Simmonds, told me that this is the third year of flowering the plants in the same pots. Three bulbs are grown in each ten-inch pot, and the plants showed remarkable vigour and flowered with great freedom. One bulb of L. auratum, however, carried an extraordinary inflorescence which must, I think, constitute a record. Throwing a single, but fasciated stem, this divided at a height of five feet into several short umbels, the whole producing a monstrous head with a total of forty-eight flowers. The individual flowers, although relatively small, were perfect in every way.

It is recorded that a single plant grown in a pot was shown at a meeting of the Royal Horticultural Society in September, 1884, carrying twenty-five flowers, the stem being fasciated and the flowers borne in two distinct umbels; it would be interesting to know if there are other records of such a large number of flowers. *W. A.*

ORNITHOGALUM NUTANS.

Ornithogalums are not largely grown in ordinary gardens although some of the hardy species are far from deserving neglect. The one most generally cultivated, if we can write "cultivated" of a bulb which is usually left severely alone to its own devices, is O. umbellatum, the Star of Bethlehem. It can well look after itself, as it increases with remarkable freedom, both by offsets and seeds. The one under notice, O. nutans, the Nodding Star of Bethlehem, is of quite a different character. Instead of forming compact masses of small flowers rising but little above the soil, it throws up very elegant spikes of silvery-grey flowers, prettily lined with light green on the exterior and silver-like in appearance. The flowers are of good size, and the plant is perfectly hardy.

It is by no means an expensive bulb and is eminently adapted for naturalising in woodlands and out-of-the-way spots. It is also pleasing on large rockwork, where it looks best when rising through Mossy Saxifrages, Arabis and plants of similar carpeting habit. It is very pleasing seen rising through Myosotis or purple Aubrietia. The flowers are generally produced in May and June. It is a native of Britain but does not appear to be widely spread in nature. O. nutans was figured in the *Botanical Magazine*, t. 269. The height is given in some works of reference as six inches, but it grows taller than that in good soil. A variety called Bouchanum is said to exist but I am not aware of its whereabouts. *S. Arnott.*

ORCHID NOTES AND GLEANINGS.

SUMMER-FLOWERING CYPRIPEDIUMS.

The Cypripediums with handsomely tessellated foliage form a useful and very free-flowering group of Orchids. Such sorts as C. Lawrenceanum, C. Hyeanum, C. callosum var. Sanderae, C. Curtisi var. Sanderae, and C. Enchantress, have been producing flowers for many weeks, while the robust-growing C. Maudiae often produces two crops of flowers in the year; the beautiful foliage of well-grown specimens is very attractive even when the plants are not in flower. Specimens that have passed out of flower may now be repotted, if necessary, the thick, fleshy roots generally keep close to the surface of the soil, therefore pans are suitable receptacles. Ample drainage is necessary; especially if deep pots are used, while a compost of A.1 fibre and chopped Sphagnum-moss should be quite suitable as a rooting medium, working it in carefully between the brittle roots and finishing off with a little extra Sphagnum-moss on the surface. Loam is not necessary for these Cypripediums.

A little extra shade during bright weather should be afforded until the roots are established in the fresh compost. These plants grow well at the warm end of the intermediate house, and if given moist conditions, quickly re-establish themselves. Water should be afforded carefully to the roots as advised for other newly-potted Orchids, and the roots and growths should be thriving vigorously before the plants are allowed to flower again.

The warm-house kinds, such as C. Rothschildianum, C. Sanderianum, C. Stoneii, C. Druryii and others that are now commencing to grow again, may be repotted now. Use well-drained pots and a compost of equal parts of fibrous loam and finely-cut A.1 fibre, and one part of chopped Sphagnum-moss, adding crushed crocks as the work proceeds. Shade the plants from strong sunshine and water them very sparingly until the roots are moving well in the fresh compost. *W. G.*

HARDY FLOWER BORDER.

ASTER ALPINUS VAR. PEGGY.

This is a remarkably fine Aster, exceedingly beautiful and quite capable of adding not a little to the attractions of the hardy flower border or the rock garden; the large flowers are held aloft on sturdy stems and are coloured an exquisite shade of silvery-blue or greyish-blue—it is a shade not easily described but one of unusual beauty. The golden centre enhances the attractiveness of the flower and endues a group with a most striking appearance.

This is a really good plant, one to thrive in any tolerably good soil; the colouring of the flowers will harmonise with that of a wide variety of other plants and is especially noteworthy when used in a grey or blue border. A pleasing association which I recently encountered was this Aster and Campanula Telham Beauty, each a companion to the other. *Ralph E. Arnold.*

CRAMBE TATARICA.

One of the most handsome of the Crucifers for the herbaceous border is Crambe tatarica, I believe it is a native of Hungary, where it is known as "Tartar Bread," some of the Crambes being of economic value and grown as vegetables.

A plant of C. tatarica in flower here during June was quite the glory of the border, just the one spike, but what a spike! Fully five feet high and with a diameter of four feet or more, the gracefully branching stems bearing on all their length multitudes of large white flowers, reminiscent of a Gypsophila but larger and handsomer. The whole plant in fact, when in flower, reminded me strongly of some Gargantuan Gypsophila, but even more graceful, with the exception of the leaves, which are large and glaucous and slightly rough, rather like those of a Bocconia.

The plant sets a good crop of seeds, and increases readily by means of root cuttings. A good mass of it effectively combined with some heavier subject would be a very telling feature in the herbaceous border during its season. *Will Ingwersen, The Birch, Sharpthorne, Sussex.*

SMILACINA RACEMOSA.

Smilacina racemosa is a graceful Liliaceous plant inhabiting moist copses and thickets, and is distributed over the greater portion of eastern North America. From a fleshy, rhizomatous root stock the aerial stems are produced. These are slender and arching, usually finely pubescent above and are from fifteen inches to thirty-six inches in length. The foliage is very decidedly attractive, the leaves being arranged in alterate fashion, the upper sessile and the lower very shortly petioled. They are oblong-lanceolate to oval in shape, and are from four inches to seven inches in length and almost half as broad. The under-surface is finely pubescent while the margins are minutely ciliate. Both surfaces are somewhat glossy and the strongly-marked nerves, together with the rich, but delicate, green of the foliage, add to the attractiveness of this plant.

The flowers are borne on very short pedicels in a terminal, racemose panicle. Individually they are insignificant, but in the aggregate they form a pleasing inflorescence much resembling in general appearance a spray of a white Astilbe, and exhaling a pleasing odour. The fully-developed flowers are creamy white and the unopened buds delicate green in colour. They are borne during May and June and are succeeded by aromatic berries, which are bright red, speckled with purple markings. The berries are about a quarter-of-an-inch in diameter.

Known colloquially by the name of False Spikenard, Smilacina racemosa is a pleasing and worth-while plant for the woodlands or wild garden. *T. H. Everett, New York, U.S.A.*

ACONITUM LYCOCTONUM.

This decidedly pretty Monkshood merits a place in many floral schemes and by virtue of its charming port and the pale yellow colouring of its flowers, lends itself to delightful combination and harmony with many other plants.

In that fine work *Some English Gardens*, by George S. Elgood, and Gertrude Jekyll, there is a delightful reproduction of Lilium candidum and Aconitum Lycoctonum intermingled; it depicts a quietly-coloured but not the less beautiful scheme, where the amply-branched inflorescences of the Monkshood are in pleasant contrast to the upright and equally graceful flowering stems of the Madonna Lily. The luminous, sulphur-yellow of this Aconite provides an ideal foil to the purity of the fine old Lily.

The fine dark green and glossy leaves of this Monkshood persist into the late autumn and are very ornamental. A native of Austria and the Tyrol, A. Lycoctonum is a good plant for the copse or thin woodland, for the mixed flower border, the streamside or in wood clearings. The plant enjoys a rich, deep, soil and is easily increased by division of the roots. It is well to remember the poisonous nature of the roots of Aconites, and the necessity to keep these plants away from all edible roots.

A Lycoctonum grows from three feet to five feet high, and flowers from late June to September.

PAEONIA VEITCHII.

This remarkably fine herbaceous perennial was introduced from Western China, by Mr. E. H. Wilson, somewhere about 1909; a unique feature of the plant is the production of several blooms on the same stem; the colour is purplish-crimson, and each flower is nearly four inches in diameter. A well-grown specimen is unusually handsome; the somewhat pendulous blossoms are carried upon wand-like stems richly furnished with graceful foliage, each glossy green leaf divided into fifteen segments—a charming picture of grace and colour.

P. Veitchii succeeds in a rich, somewhat retentive soil and, like other Paeonies, dislikes disturbance. P. Veitchii was figured in *The Gardeners' Chronicle*, 1909, Vol. II, p. 2, fig. 1. This species, P. Delavayii, and some others, are capable of creating an interesting feature in the garden; as foliage plants they are strikingly handsome and few plants exhibit so perfect a balance between flowers and leaf. *Ralph E. Arnold*

RHEUM ALEXANDRAE.

The stately and impressive Rheum Alexandrae is at present growing in the gardens of Captain and Mrs. Stewart of Shambellie, Kirkcudbrightshire; it withstood the past winter without apparent injury and is looking well this year.

The plant is still rare in gardens, but is deserving of a place for the sake of its bold, three-feet-tall growths and its yellowish, oval bracts, flopping on the spike. A good group of R. Alexandrae would look well in an open place in the woods. *S. A.*

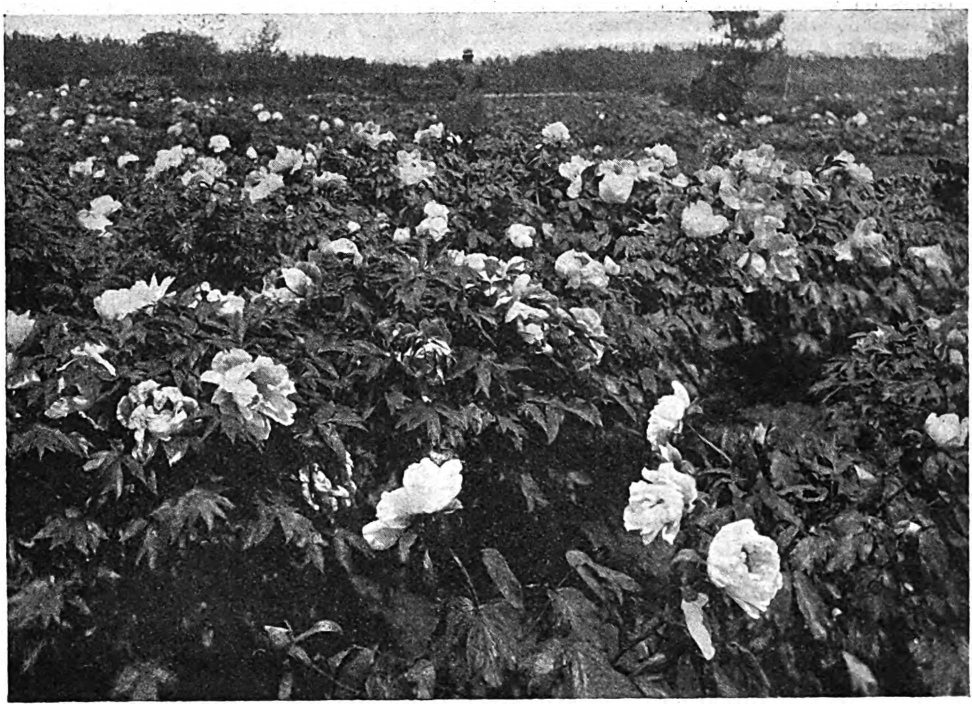

FIG. 60.—MR. JITARO NAGAO'S PAEONY BEDS IN NORTHERN JAPAN.
(see p. 131.)

TREES AND SHRUBS.

PONTENTILLA DAVURICA AND P. FRUTICOSA VAR. MANDSCHURICA.

These Cinquefoils are a couple of very charming rock-garden shrubs and they are quite distinct from any of the others, which in a race so confusing is no small merit. P. davurica, a native of Siberia and other parts of northern Asia, makes a very compact, twiggy and dense little bush. It grows slowly and seldom attains a height of much over a foot. The green leaves, of five leaflets, are deciduous, about an inch long and free from hairs. Although the prettily-rounded, white flowers, averaging one inch across, are much like those of other shrubby Potentillas, the fact that they are borne singly, together with the erect, close habit of growth, and smooth leaves, will serve to identify this species should doubt arise.

P. fruticosa var. mandschurica is even more delightful than the above, for it has a more elegant manner, extending its almost prostrate branches laterally and delighting to spread them over the face of a sunny rock. It has never exceeded six inches in height here, but will in course of time cover a space two or three feet across. Like the type, this variety is deciduous, the rather large leaves being slightly silvered with a grey down. The pure white flowers are also a good size, well over an inch in diameter and they are produced with the utmost freedom nearly all the summer. Both of these shrubs are, of course, perfectly hardy and of easy culture in any free soil. I grow them in a stony, gritty loam of the most meagre description. They enjoy full exposure and appear to be as indifferent to drought as they are to our changeful winters. *N. Wales.*

GENISTA AETNENSIS.

The Mount Etna Broom is one of the most useful of the tall species, as it flowers during July. Growing, with age, up to at least twenty five feet in height, Genista aetnensis is an attractive subject for wide shrubbery borders, and, when space permits, massing on a sunny slope in the pleasure grounds.

In course of time the old branches become rather gaunt and sparse in appearance, hence it is more effective in groups than cultivated as single specimens. The golden-yellow blossoms are freely disposed, singly, on the pendulous young branchlets. Seeds are freely produced and provide a ready method of increase.

Grow the plants in pots until large enough to place in their permanent positions as it is one of the least satisfactory of Brooms to transplant from the nursery border. *A. Osborn.*

NOTOSPARTIUM CARMICHELAE.

The note by *North Wales* regarding this fine New Zealand Broom (page 47) is of much interest. There has been a fine plant in the rock garden at Orchardton, Castle Douglas, in the Stewartry of Kirkcudbright, for many seasons, and it has flowered well for years. It was badly cut one severe winter about fifteen years ago, but recovered in time and has thriven since. I understand that it withstood last winter quite well. I have a small plant which has withstood two winters. In that of 1927-8 it suffered from frost after a wet autumn, but grew away again. In the winter of 1928-9 it suffered a good deal, but is alive and making fair growth. My plant is close to a south-west wall, in a dry border. After the experience of last winter, I have no fear of the Notospartium here, and hope it will come into bloom in some future year. By the way, several branches of the Moonlight Broom (Cytisus scoparius var. pallidus), were killed last winter and had to be cut off, but it was fully exposed to cruel winds during the severe frost. *S. Arnott.*

THE GENUS PRIMULA.

(*Continued from p.* 108).

POLIA (Craib). Brake P.

(Petiolaris-Davidii).

THIS charming perennial species has a stout, thick root-stock clothed with thin, brownish scales. The leathery leaves, in tuft, have elliptic or egg-shaped-elliptic, rarely oblong-elliptic, blades, usually rounded at the tip and tapering at the base to a stalk, in all nearly six inches long; margins furnished with sharp, sinuous teeth fringed with minute hairs; upper surface smooth, underside clothed more or less sparsely with white meal. Flower stem four to five inches tall, sparsely covered with minute down. Flowers, two to ten in an umbel, rose, blue or violet. Corolla about one inch across, divided into five broadly heart-shaped segments, bilobed at the tip; tube about three-eighths-of-an-inch long with a conspicuous ring in the mouth. Flowers in May.

Grows on woody hillsides, in rocky woods and Bamboo thickets, in Yunnan, western China, at from 6,000 to 7,000 feet above sea-level.

Culture; Good Oak or Beech leaf-soil and fibrous loam, in a cool, shady spot, should suit it.

POLYNEURA (Franch.). Many-nerved P.

(Cortusoides.)

This hairy, perennial species produces a tuft of almost circular leaves, from three-quarters-of-an-inch to two-and-a-half inches across the blades, which are borne on rounded, downy stalks from four to eight inches long; margins divided into about eleven broadly oval, blunt lobes which are furnished with blunt or sharp teeth on their margins; upper surface downy, underside clothed with longish, woolly, grey hairs. Flower stem four to sixteen inches tall, bearing a solitary umbel, or from two to three superposed umbels, of purple blossoms, on rather long stalks clothed with grey down. Corolla half-an-inch to five-eighths-of-an-inch across, divided into five deeply bifid, heart-shaped lobes; tube cylindrical, twice as long as the calyx.

Grows in cool, shady places on mountains near Kiala, in Szechuan, central China.

Culture: Good loam and leaf-soil, in a cool, shady spot, are the conditions indicated.

POLYPHYLLA (Franch.). Many-leaved P.

(Denticulata.)

A small, perennial plant probably of not long duration, with a rosette of oval-lance-shaped, blunt or pointed, membranous leaves, tapering into a stalk which is sheathing at the base, in all five-eighths-of-an-inch to one-and-a-half inch long. Flower stems two to three inches tall, bearing an umbel of six to eleven violet or pale lilac blossoms on very short stalks. Corolla about a quarter-of-an-inch across, funnel-shaped, divided into five broadly heart-shaped lobes cleft to the middle; tube cylindrical, a little longer than the calyx. This plant is, according to the latest grouping, a sub-species of P. pseudodenticulata (Pax.) Flowers in September. Not in cultivation.

Grows in damp, peaty pastures at Lan-Kong, near Tali, in Yunnan, western China, at 10,000 feet above sea-level.

Var. monticola (Hand.-Mazz.). A more robust plant than the type, with densely toothed leaves; the yellowish, oval, herbaceous scales which form the resting buds are about one-and-a-half inch long, and are persistent until the foliage dies down. Damp mountain pastures in northern Yunnan and Szechuan, at from 7,800 to 9,750 feet above sea-level.

Culture: As for P. denticulata.

PRATICOLA (Craib). Meadow P.

(Petiolaris-sonchifolia.)

A dwarf, herbaceous, perennial species with a tuft of thin, green, spathulate leaves about one-and-a-half inch long, rounded at the tip, wedge-shaped at the base, ending in a more or less distinctly winged stalk; margins thickly furnished with small, sharp teeth. Flower stems two to three inches tall. Flowers purplish-blue, about five-eighths-of-an-inch across, divided into five broadly wedge-shaped or egg-shaped, blunt lobes whose margins are furnished with three sharp teeth; tube cylindrical, about half an-inch long. Flowers from April to July.

Grows in open, moist, stony pastures on the mountains of the Shweli-Salwin Divide, in Yunnan, western China, at 10,000 to 11,000 feet above sea-level.

Culture: Good calcareous loam, in a damp, but open spot, should suit it.

PRATTII (Hemsl.). Pratt's P.

(Nivales).

A smooth, dwarf, perennial species with a rosette of lance-shaped leaves from one inch to three inches long, pointed at the tip and very narrow at the base; margins nearly entire. Flower stem four to six inches tall, bearing a many-flowered umbel of bright yellow blossoms. Corolla about half-an-inch across, lobes heart-shaped; tube cylindrical below, slightly dilated upwards. In cultivation in 1920.

Grows in damp, rocky, exposed places, on the mountains of Szechuan, central China.

Culture: It should succeed in good calcareous loam, in a damp spot.

PRENANTHA (Balf. f.). Rusty-stemmed P.

(Candelabra.)

A small-flowered, perennial species with a rosette of few, papery leaves from four to five inches long, with oblong, egg-shaped blades, rounded at the tip, tapering to a winged, sheathing stalk about twice the length of the blade; margins furnished with irregular, horny-tipped teeth; upper surface channelled lengthwise, underside greyish-green, intricately veined, probably somewhat mealy. Flower stem reddish, about six inches tall, bearing one, rarely two, superposed umbels of four to seven yellow, fragrant blossoms, on curved stalks about half-an-inch long. Corolla about a quarter-of-an-inch across, with nearly square, erect, retuse lobes; tube cylindrical, nearly twice as long as the calyx. Flowers in June and July.

Grows in damp situations in the Sikkim Himalayas, near Jongri, and near Talung, at 9,000 to 12,000 feet above sea-level.

Culture: As for P. Poissonii. *A. W. Darnell.*

(*To be continued*)

THE CULTIVATION OF NEW ZEALAND PLANTS IN BRITAIN.*

(*Continued from p.* 108).

MODIFICATIONS AND NATURALISATION.

SEVERAL of our plants, under the influence of new climatic conditions, have altered their habit a good deal. The most remarkable instance of this that came under my notice was Muehlenbeckia ephedrioides, as grown in the rockeries at Edinburgh. It is here a quite leafy plant, taller and more luxuriant than I have ever seen it as a native. I noticed the same kind of modification in the case of Carmichaelia Enysii (in Edinburgh and elsewhere) and in Coprosma Petriei, which in some places hardly forms a mat at all. But the most extraordinary of these changes, I thought, was to be seen at Tresco Abbey, where the Pohutukawa (Metrosideros tomentosa) may be seen, not only putting forth aerial roots (which I do not think it ever does with us), but also sending down branches which, in reaching the ground, take root like those of the Indian Banyan tree. In Guernsey, also, Cabbage Trees sometimes send out aerial roots—perhaps they do this in New Zealand, but not to my knowledge.

Among plants which have changed more or less—usually in the direction indicated above—I noted Myosotis Traversii (at Edinburgh), Raoulia glabra (at East Grinstead), Helichrysum Selago, Muehlenbeckia axillaris and Poa Maniototo (at Edinburgh).

To show how "willing" some of our trees are in the congenial climate of the Scilly Isles, I may add that Nothofagus fusca has there grown to eighteen feet, a Kauri to fifteen feet, and Pseudopanax crassifolium to twenty feet, all in twenty years.

PARTICULAR GARDENS.

Without going into detail, I may state as a result of my observations that, as already indicated, Edinburgh and Tresco Abbey stand out as the best worth study of all British gardens where our plants are grown; that the rockeries and gardens at Kew are very rich in Veronicas (about seventy-five species are named); that Mr. Millard of East Grinstead has had very great success in growing our alpines, and has in cultivation some few plants that I have not seen elsewhere (*e.g.*, Myosotis decora and Wahlenbergia saxicola); that the gardens at Wakehurst Place contain a very great number of our alpine plants, while the greenhouses are rich in our subtropical species; that both Captain Simpson Hayward and Major Johnson, in Gloucestershire, have interesting collections—at Icomb Place, for instance, I saw fine, large specimens of the Niggerhead (Carex secta), which I saw nowhere else; that the Ludgvan Rectory garden, although small, is exceedingly interesting—here may be seen, for instance, the "Honeysuckle" (Knightia excelsa); three or four of our Ratas, and as many of our Beeches; Pittosporum Dallii; Dodonaea viscosa, Cordyline indivisa, and Senecio Hectori; while the churchyard, adjoining the garden, is embellished with a dozen fine Cabbage Trees and several examples of Olearia Forsteri; and that a very fine collection of our hardier shrubs and trees is included in the vast cultivations of the Hon. Vicary Gibbs at Aldenham House, where they are looked after by a specialist and named with unusual accuracy.

If I were asked what were the most successful single plants, from the gardener's point of view, seen by me in Britain, I should not find it easy to reply. The peculiar conditions in the Scilly Isles give Tresco a very great advantage, over all competitors, and it would be agreed I think, that the Pohutukawa in full bloom, as it may be seen here, in July, is the finest thing of its kind in the running. A particular plant of the Phormium tenax in the Rectory garden at Ludgvan was very hard to beat. It is a variegated form, fully twelve feet high, with extremely broad and lusty leaves. Then there was a specimen of Olearia macrodonta in bloom at Wakehurst Place in August, which we all admired immensely; in fact, no finer garden shrub could be imagined. This plant is at least twelve feet high, and has achieved a massive rounded form, of perfect shape, no less than thirty feet in diameter, and this was a mass of white blossom.

It was pleasant to find that few of our plants, if any, were making themselves a nuisance. At Edinburgh, however, it was noted that our little Pratia angulata had established itself in the lawns, and was rapidly spreading (as it sometimes does in Christchurch), its direction of movement being downhill—rather a remarkable thing I thought. And in one garden I found that our innocent little Epilobium nummularifolium was spreading in the rockery. as it always tends to do, and that the proprietor was always rooting it out, and cursing it very heartily. I am told that Nertera depressa, in western Scotland, spreads in lawns, as Pratia angulata does.

PARTICULAR GENERA.

Looking back over my lists of New Zealand plants cultivated in Britain (of which a complete catalogue will be published later) I find that the various genera (the more important groups only) are represented as summarised below. It will be seen that a very large part of our flora is here, although there are some remarkable gaps to be dealt with later on. Major Dorrien Smith

---

*By Professor Arnold Wall, Canterbury College, Christchurch, N.Z. Reprinted from *The Press*.

is sure that he has had at one time at least two-thirds of our whole flora in the gardens at Tresco Abbey, and that he has now about half of it, but I think that in this computation the grasses, Ferns, Cyperaceous and Juncaceous plants, etc., have been ignored. Attention is here concentrated upon plants grown in the open.

The following account is not intended to be exhaustive and is not to be taken as quite authoritative. I have no doubt that I have missed some things; either I did not visit the particular garden where some plant, here unmentioned, is cultivated; or passed other by in the all-too-hasty examination of the vast extent of the Edinburgh Rockeries, or the great jungly plantations of Tresco Abbey, or the great area of cultivations at Aldenham House and Wakehurst Place.

Veronica, as our largest genus, has, of course, received the lion's share of attention. Most of our Veronicas are here, in one place or another, and a great many more which are hybrids or not identifiable with certainty. Among those which I have not seen or heard of on this side are V. Gilliesiana, V. Haastii (although this name is often applied to quite other things), V. Thomsoni, V. pulvinaris, V. Raoulii, V. salicornioides (although the name occurs), and V. spathulata. I listed so many as seventy-five named species at Edinburgh alone, and there are others there which are hard to name.

Ranunculus is much neglected. Many try to grow R. Lyallii, mostly in vain, and R. Buchanani is at Edinburgh, also R. Matthewsii, the natural hybrid; and R. insignis is fairly frequent; but I have not seen one of the other forty or so of our Buttercups.

Olearia is a great favourite. All the commoner species are grown, especially O. macrodonta (and varieties), O. ilicifolia, O. virgata and O. odorata. In one place or another, I think I have seen all our Olearias except O. Crosby-Smithii and O. operina. Olearia (Pachystegia) insignis is quite frequent and very hardy; it successfully withstood the severe winter of 1927-28 at Wakehurst.

Senecios, especially S. Monroi, S. compactus, S. Greyii and S. laxifolius, are largely grown. The smaller herbaceous species are not so frequent, but I have seen here and there S. bellidioides and S. southlandicus.

(*To be concluded*).

NOTES FROM KEW.

Two large bushes of Rhododendron auriculatum have a considerable number of trusses of open flowers at the north end of the Rhododendron Dell. This species does not commence to grow until quite the end of July, and about the same time the flower buds commence to swell, so that the large, white blossoms are at their best during the first half of August. Flowering at this season, when we expect hot sunlight, R. auriculatum should be planted in the half-shade of open woodland, or similarly protected positions. These two Kew plants are particularly interesting, being two of the original batch of seedlings raised at Coombe Wood, from seeds collected in China, during 1900, by Mr. E. H. Wilson. The bushes are now some twelve feet in height and eighteen feet in diameter.

A considerable number of plants of an interesting hybrid, R. auriculatum crossed with pollen of R. ponticum, have been flowering for the last three weeks in a bed near the Brentford Ferry Gate, and in the woodland clump near the Lion Gate. It is a very distinct cross, both in leaf and flower, the latter being of a very pale mauve shade.

A distinct group of colour is furnished by the long, feathery, rosy-pink blossoms of Tamarix pentandra (*syn.* P. hispida aestivalis), in a large, round bed bordering the Broad Walk near the Pond. The plume-like panicles are very attractive in the pleasure grounds and sunny shrub borders. The long-stemmed sprays are also valuable to use for tall vases. The Tamarisks are well-known seaside shrubs, this species being the most useful, flowering, as it does, during August, the most popular seaside holiday month of the year. The Tamarix species are among the easiest of hardy shrubs to propagate by cuttings. Cuttings twelve to eighteen inches in length, made of the ripened growths of the year, root readily if inserted on a border during November. To avoid the check of transplanting a year later—if it can be so arranged—insert the cuttings in the positions where the shrubs are to remain.

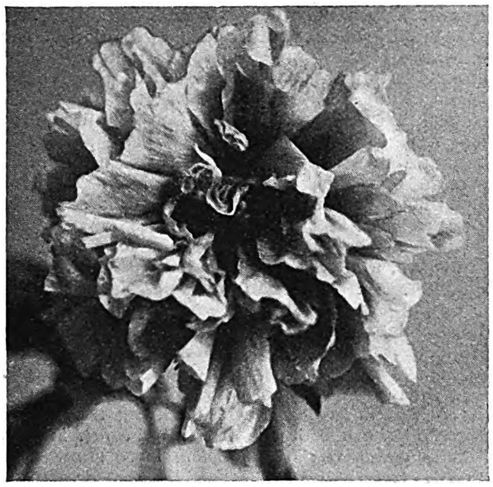

FIG. 61.—PAEONIA MOUTAN VAR. NISHIKI-NO-TSUYA.
(see p. 131.)

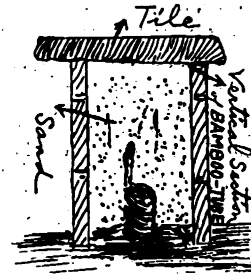

FIG. 62.—PROPAGATION OF PAEONIA MOUTAN.
(see p. 131).

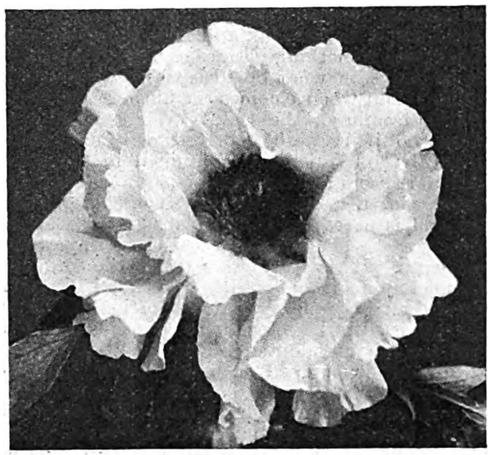

FIG. 63.—PAEONIA MOUTAN VAR. OBOROTSUKI.
(see p. 131.)

The Shrubby Pavia, Aesculus parviflora, is a very distinct and useful subject for shrubbery borders, and as a large specimen lawn bush. The average height is from nine feet to twelve feet, the diameter often more than this, as it produces suckers freely. The flowers are white, produced freely during August on slender, cylindrical panicles. Ripe fruits are very seldom produced in British gardens, but the free production of sucker growths provides a ready means of increase by division.

Rosa Wichuraiana is best known as one of the parents of a large number of the later-flowering, rambling and climbing Roses, including such popular favourites as American Pillar, Alberic Barbier and Lady Gay. Rosa Wichuraiana is, however, worthy of attention as a trailing shrub, producing clusters of white blossoms along the slender growths during late July and in August. It is useful to plant on sloping banks, and it is most attractive if allowed to trail over and hide old tree butts. Even when not in flower the glossy, dark-green foliage is attractive.

The Sorbaria group of Spiraeas, with their pinnate foliage and large panicles of feathery white blossoms is flowering freely. S. Aitchisoni nine feet to ten feet or more high; S. Lindleyana, an imposing tall shrub up to fifteen feet or more in height; S. arborea var. glabrata, one of Mr. E. H. Wilson's introductions from Hupeh and Szechuen, averaging eight feet to ten feet high; S. sorbifolia, some four feet high and dwarf in comparison with the foregoing; and S. stellipila, a Japanese Sorbaria, three feet to four feet high, with leaves very distinct to the touch as the undersides of the leaves is clothed with stellate hairs, are all showy subjects in the collection near the Pagoda.

Several of the true Spiraeas flower during July and August. The most useful to brighten the shrubbery borders during August include the dwarf S. japonica varieties, Anthony Waterer, carmine-red; Bumalda, carmine, and alba, white; the two white-flowered varieties of S. salicifolia—latifolia and paniculata—five feet high; and S. Menziesii var. triumphans, an upright growing shrub up to about six feet high, with close panicles of rich rose-coloured blossoms.

The two American Stewartias, S. Malachodendron and S. pentagyna, are flowering freely in sheltered beds of Ericaceous shrubs. These shrubs were far from happy, despite frequent watering, during the hot, dry weather of July, but the cooler conditions of the past ten days and good rains have wrought a speedy change in the appearance of the plants. Only the later flowers of S. malachodendron remain, but several plants of S. pentagyna are freely sprinkled with the attractive white blossoms, each three to three-and-a-half inches in diameter.

Another shrub which thrives best at Kew when surrounded with the Mediterranean Heath, three feet or more in height, to keep the ground cool and moist, is Eucryphia pinnatifolia. Specimens from four feet to fifteen feet high are flowering freely in various parts of the Gardens. The large, white flowers, with large tufts of stamens, suggest white Hypericum blooms, if such were possible. Layering and seeds provide ready means of increase, although for the first two or three years growth is comparatively slow. After this period, however, growth is very good, and the plants flower freely annually.

The numerous forms, or varieties, of Buddleia variabilis provide a wealth of colour during late July and August. This is appreciated as much, or more in comparison, in small gardens, than large, for Buddleia variabilis is becoming quite a common shrub in small town and suburban gardens, where it flowers surprisingly well under, ofttimes, far from ideal conditions.

Numerous hybrids or varieties of garden Clematises are flowering freely in the Duke's Garden and elsewhere. The most interesting group in the collection of Clematis, not far from the Victoria Gate, is C. rubro-marginata. This is a climber of slender growth, and deliciously fragrant, small, reddish-purple blossoms with white centres. It is a hybrid between C. flammula and C. viticella. *A. Osborn.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar,* 7818.

PROBLEMS OF PLANT LIFE*

VI.—Transpiration.

IN our recent study of the Significance of Wilting (p. 71) so many references were made to transpiration that requests have been received for further information about this problem of plant life in the light of recent research. In the old days everything was very simple and easily accounted for. It was then enough to state in general terms that the sap rose in a plant because the sun shone or the light fell on it. This caused evaporation, and to meet the need moisture was drawn up from the soil. In one respect this popular way of stating the case was true enough. In the words of one of our most recent authorities, "the direct source of the energy used in the suction of transpiring leaves is the radiant energy of the sun." But when we come to enquire how and why this is we soon discover either the profoundest ignorance or the most divergent opinions. In the view of one authority, transpiration is only an evil; by another it is regarded as an inestimable boon. What seemed, moreover, to be a purely mechanical process is now found to be dependent on many causes, while the ends which are served by transpiration vary considerably.

It may be laid down as a general law that transpiration is a physical necessity; that it is functionally as important to a plant as breathing is to animals. In some respects, indeed, the processes of breathing and transpiration are one and the same, so that it has been the habit to speak of the stomata found on the leaves of a plant as its lungs and breathing pores. The analogy is not perfect in every respect, but that is a point which need not be laboured here. If, however, transpiration is essential to the life of the plant, a knowledge of the process is obviously of great importance. It follows, too, that if it is a life-process it must be advantageous. Yet it has been stated that it is sometimes definitely injurious, which shows that the horticulturist ought to be well-informed on the subject. If transpiration is ever detrimental to a plant, what are the conditions, and how may they be controlled? Here is a subject which clearly merits the most careful attention of the teacher.

We may begin by stating an all-important fact, viz., that during the life-time of a plant large quantities of moisture are passed through its tissues, and discharged by the process known as transpiration or evaporation. The quantity will, obviously, vary with the size and nature of the plant, its length of life, the extent of the water supply, meteorological conditions, and other factors, all of which have to be studied carefully. The fact having been established, it follows that one enquires into the meaning. What, it has been asked, is the significance to the plant of this continuous stream of water passing through its organs? Is it enough to state that just as it is a law of physics that water will find its own level, so it is a physical necessity that plants should transpire, and that transpiration has no further significance? Or shall we say that just as breathing is a physical necessity to man, but is also beneficial, so transpiration also serves some important end in the economy of the plant? If so, we shall be led to enquire whether light, heat, atmosphere or other factors are necessary as well as water, and what bearing these may have on the one or the other. The *fact* is that plants transpire; the *problem* is to show why and how.

We must be content for the present to assume the presence of root-processes on the one hand for the extraction of water from the soil, and of stomata on the other for its transpiration. Into their various modifications we need not enter at this point, since they constitute problems by themselves. There are some who contend that transpiration is an evil. It is granted that under present conditions it is a necessary evil, inevitable and unavoidable, but an evil nevertheless. The case may be stated thus. Most plants are supplied with leaves by means of which they are fed. Depending largely on carbon dioxide they must keep open communication alike with the air on the one hand and the water supply on the other. But if the atmosphere is dry it will naturally tend to draw off the water from the leaves, and this process is known as transpiration. The drier the air the greater the transpiration, or the more severe the tax on the water supply. It follows that if the latter is limited the plant will ultimately wilt, lose its turgidity, cease to maintain the water current, and so eventually die for want of nutrition. The advocates of this theory state that to this cause we may trace a variety of modifications and adaptations in plant forms.

The whole of the case cannot, however, be stated so simply. So far from being an inevitable evil, transpiration may be shown to be one of the most necessary and useful of plant functions. It will be observed that we qualified the remark about the dependence of the plant on carbon dioxide. As man does not live by bread alone, so the Oak and Ash, the Rose and Briar need something besides carbon. That may be to the plant what bread is to man—the staff of life. But whence comes the blush of the Rose or the tannin of the Oak? What would the plant do if it were deprived of the various mineral salts which are contained in the soils and fertilisers? Experiment shows that the passage of a continuous stream of water from the soil is necessary if the plant is to secure a steady and sufficient supply of these important elements. It is just here that the organic chemist joins hands with the horticulturist. Careful analyses show what proportion of this or the other salt is necessary to vigorous growth, and the means adopted by the plant to secure the supply is summed up under the term transpiration. Since plants cannot take up solids all nutrients have to be in solution. The stomata of the leaves give off excessive moisture, while the salts held in solution are used up by the tissues.

This, however, is not the only benefit which the plant derives from the transpiration process. By pumping up water from the soil the leaves maintain the succulent plant in a state of rigidity or turgidity, and thus enable it to function properly. If we take by way of illustration the act of cross-fertilisation, we see at once that this will be seriously affected if the plant becomes flaccid. Maintain normal transpiration and you enable the organs to function.

There is, further, the effect which this process has upon the plant during the heat of the day, in modifying the effects of the sun's rays. A leaf which fails to transpire normally becomes hot, dry, and useless, whereas it has been found that the temperature of healthy leaves is only slightly above that of the surrounding air even when the plant is exposed to the full heat of the sun. This is a matter of great importance, and has much significance for those who grow plants in greenhouses and hothouses. It is not suggested that the foregoing considerations by any means exhaust the subject. It must, however, be concluded that so far from transpiration being an evil, it is of immense advantage to plant life, and deserves the most careful thought and study. *Hilderic Friend.*

THE DURATION OF CUT FLOWERS.

NOT the least of the demands made upon the present-day gardener is the continuous supply of cut flowers for the decoration of rooms and dinner tables, therefore the variability in the lasting properties of the material used for these purposes is of peculiar interest.

While some flowers, such as Heliotrope, for example, are so fugacious as to be scarcely serviceable, others, in particular Carnations, sometimes remain fresh for weeks under reasonably good conditions. The lasting properties are not necessarily uniform within certain groups or genera, for while the common Poppy lasts but a day or two under the best conditions, its congener, the Iceland Poppy, which appears to be of similar substance, lasts for many days. Among Irises, the bulbous section, including the Dutch, Spanish and English groups, have excellent lasting qualities, but the same cannot be stated of the varieties of I. germanica, so remarkable in the open border by reason of their handsome flowers of delicate texture and infinite variety of colour; yet the Japanese Irises, if cut while still in the bud stage, will unfold their petals perfectly and remain fresh for several days although their season of flowering is at the hottest period of the year. I. sibirica and its varieties, the larger-flowered I. aurea, I. spuria and I. ochroleuca also possess this property, and are particularly valuable for big decorating schemes because of their long stems.

But the conditions under which plants are grown, and their stage of development when cut, have a very great influence on their duration. Narcissi and Tulips, both forced and when grown under natural conditions, last for a very long time if gathered just before the bud opens, but fully expanded flowers last a relatively short time. Few flowers can surpass the Carnation in its duration, but, like all other flowers, its period of freshness after being cut is largely governed by the treatment it receives.

As regards summer border flowers, everyone knows that the hot, dry summer months hasten the maturation of plant growth, and this acceleration continues to some extent even after a flower is cut. It is therefore much more difficult to maintain freshness, and care should be taken that the flowers are placed in water immediately they are cut, to prevent loss of turgidity. Amongst the most satisfactory flowers for cutting in the summer months are the Gladioli, particularly the primulinus hybrids, which, by reason of their graceful stems and brilliantly coloured flowers, make excellent decorative material. If cut when the first flower begins to expand, and placed in water, the succeeding flowers open in rapid succession to the apical flower, maintaining perfect freshness for eight or ten days, and it is one of the very few flowers which will regain rigidity, even when slightly drooping, on being put into water.

Dahlias, although admirably adapted to many decorative schemes, are not very durable in water and, unfortunately, the singles, which provide such a wealth of decorative material, are less durable than the double sorts; the decorative varieties are also more resistant than the Cactus sorts, but as the season advances and nights become cooler, flowers of all sections become more durable.

---

*Previous studies appeared in our issues of April 13 (p. 279-80), June 15 (p. 446-7), Vol. LXXXV, July 13, (p. 30), July 20 (p. 50), and July 27 (p. 71).

It is thus clear that the floral decorator has considerable choice of material for any scheme he may contemplate, while a knowledge of the general tendencies of various flowers, when cut, enables him to choose material to meet the time-needs of the scheme in question.

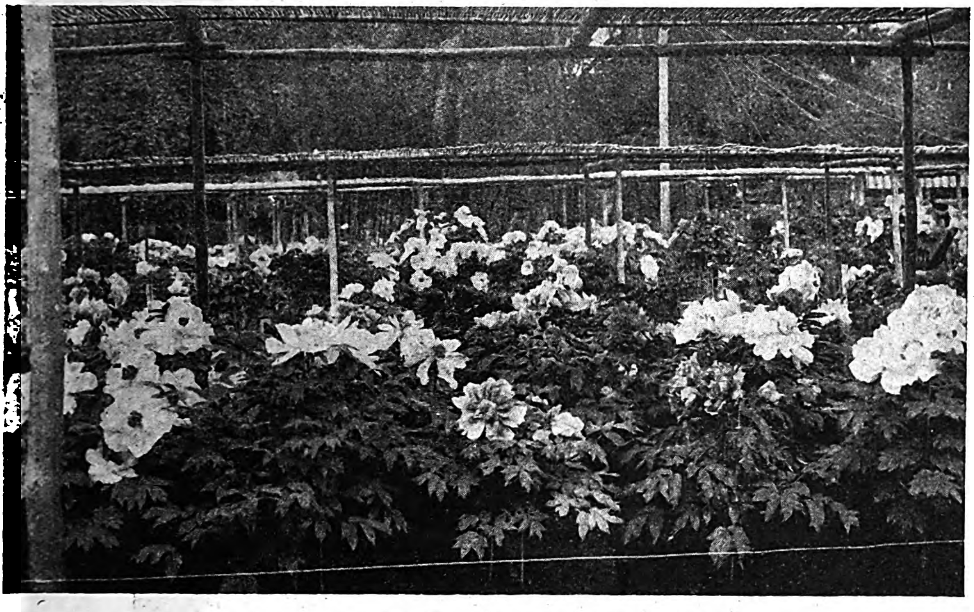

FIG. 64.—MR. JITARO NAGAO'S TREE PAEONY BEDS IN NORTHERN JAPAN.

But the exercise of a few precautions can contribute in a remarkable degree to the conservation of freshness in flowers after they are cut, particularly during dry and hot periods. During such periods loss of moisture from evaporation is very great, and flowers should only be cut in the early morning, when they are at their greatest turgescence. In the case of heavily-foliaged material it is also good practice to remove those leaves which are superfluous to decorative needs, and with large-stemmed flowers, particularly those of a woody nature, the cut should be made obliquely so as to offer a larger surface for the absorption of water. Finally, care should be taken to place them immediately into fresh water, and if a flower-room is available where the atmosphere can be kept almost at saturation point, it is a great advantage to allow the flowers to stand for an hour or two in such a room before use. It is also essential that flowers which have to be packed for long journeys should be subjected to these conditions before being packed. *W. Auton.*

TREE PAEONIES IN JAPAN.

FROM ancient times the Tree-Paeony has been called "the King of Flowers" in the East. The history of the Tree-Paeony is long and interesting, but it is not my intention to deal with it in this note. The Tree-Paeonies are much appreciated in gardens, or as pot plants, and widely cultivated from southern Japan to so far north as Hokkaido, where heavy protection is needed in winter. Yamamoto of Settsu province and Koaimura of Echigo province have enjoyed a hundred-year-old reputation for the culture of Paeonies and the raising of new varieties.

The extensive Tree-Paeony Garden (Fig. 64) at Sukagawa in northern Japan, is noted for its many aged and giant plants and numerous varieties. One hundred years old —and even older—plants freely produce their flowers annually (Fig. 65), and are not rare in the garden. The oldest plant is presumed to be one-hundred-and-eighty (or ninety) years old. The trunk is hollowed and one side is decayed, but it grows vigorously. The largest one is about ten feet in height and thirteen feet in width. The circumference of the trunk at nine inches from the ground is one foot eleven inches. The garden is open to the public by the generosity of Mr. Gentaro Yaginuma, the owner, whose life has been devoted to the cultivation and collection of varieties of Paeonia Moutan or "the Botan."

Mr. Sinzaemon Tanaka's work on the hybridisation of the Tree-Paeonies is much admired, and his name will be long remembered as that of a great raiser of Tree-Paeonies. Mr. Tanaka commenced raising varieties in 1894, after he learned the method from the *Rono Zasshi* (then a leading agricultural journal in Japan). Since then, after many difficulties and failures, he has raised nearly two-hundred-and-fifty varieties. The following are a few of the best he has raised:—Hakuo, Haku-Unryo, Nagoya-Jo, Hoo-Jo, Kanyo-Kiu, Kinpai and Godaishu. He is now eighty-one years old, but his enthusiasm is unabated (see p. 122); indeed, he works with undiminished energy and interest, raising and cultivating with his own hands. He is very tranquil regarding rewards—the work is his great interest.

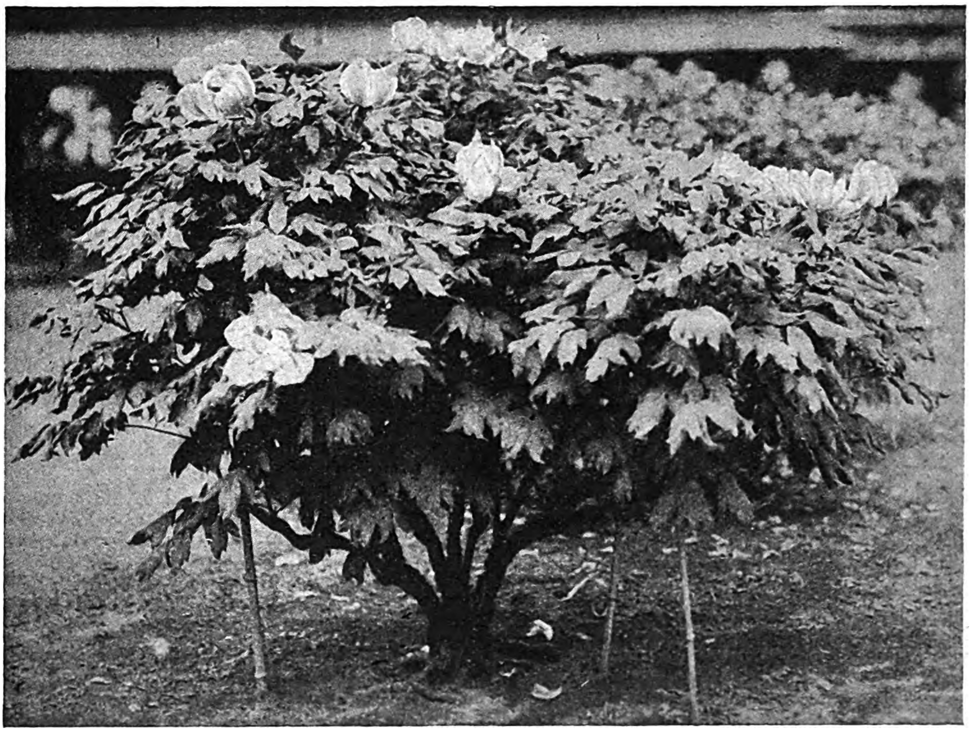

FIG. 65.—PAEONIA MOUTAN VAR. CHIGO-SAKURA.
A specimen one hundred years old in the garden of Mr. F. Yaginuma.

Tree-Paeonies like well-drained, loamy soil, enriched with well-decayed manure. Too compact soil should be avoided, since it retains water on the surface. Tree-Paeonies form and expand their flower buds very early in the year, so that autumn planting is preferable. They dislike disturbance, as we know by bitter experience when old plants are moved; they fail to grow in the year following, and their branches and trunks will often die back. Tree-Paeonies are not uniform in growth, therefore strong shoots should be shortened in autumn and they will then form two moderate branches and flowers the next year. Consequently, symmetrical growth is obtained. They are rather gross feeders, and one readily detects the difference between well-manured or semi-starved plants. When planting takes place, pulverised Rape-cake—used for Chrysanthemums, Azaleas, Morning Glories, dwarfed trees, and for nearly all the plants cultivated; it is much prized and widely used, and is far better than Bean-cake—is scattered over the surface of the ground. This should be applied in winter and just after the flowering period is finished. This manure damages the root fatally when placed in the soil instead of being scattered on the surface.

Seedling and herbaceous Paeony roots are used as stocks. The former has the advantage, producing larger flowers and causing faster growth, but has the disadvantage of forming suckers, while its roots are not suitable for pot culture, being too big. Those grafted on herbaceous Paeony roots are the best. In the Yamamoto district the former is used chiefly. Three- to four-year-old seedlings are used as stocks; these are headed down to one inch to one-and-a-half inch from the root; then a small notch is made on the side of a cross section for inserting the scion. One- or two-eyed scions, one-and-a-half-inch to two inches in height, are cut with a flat, sloping, slice-cut on the lower half. After the scion is inserted it should be very tightly bound with Ramie, Hemp, or straw, and covered with oil-paper. Then a Chusan Palm rope is wrapped firmly round the point of junction. The season for grafting is from September 1 to early in October. The grafted plants are placed in a nursery bed and enclosed by a Bamboo tube as shown (Fig. 62). The sand nearly fills the Bamboo tube and protects the graft from drying, besides retaining warmth. A piece of tile is also put on the top to afford protection from rain. The tile is taken away when spring comes, but the Bamboo tube is left in place until the young growth has developed for one foot or so. Sometimes the grafted plant is covered with a mound of soil instead of a Bamboo tube; this method is freely practised. The flower bud formed in the following spring should be cut off, and the plant will attain a height of about one foot to one-and-a-half foot by the autumn.

The methods of seed-sowing, crossing and culture are not much different from those practised in connection with common shrubs.

The following are the best Japanese varieties of Paeonia Moutan:—Teikwan, vivid crimson, double; Fujisome-Koromo (Fig. 59), dark purplish crimson, fading towards the tip, very large, semi-double; Hinotsukasa, brilliant dark crimson, very fine, double; Nishiki-no-Tsuya (Fig. 61), crimson, with dark, bright crimson centre, highly raised petals, double; Tamasudare, snowy-white, double, one of the best whites; Gunpo-Den, of a colour difficult to describe, raised petals, double, the best in purple shades; Oborotsuki (Fig. 63) white, with pinkish-purple centre, large, semi-double; Kokuho, very dark purplish-crimson, double; Momoyama, soft pink, curled petals, double; Sin-Kagura, dark crimson, with raised petals, very double and one of the largest flowers; Konyo-Kiu, yellowish, double; Tsukumo-Shishi, lovely peach-colour, narrow petals, double; Hinode-no-Sekai, fine pure crimson, one of the loveliest in colour, most floriferous, and the best for pot culture.

The case-weaver often damages the buds in early autumn. Fallen petals should be collected, as they cause disease when they decay on the branches and stems.

Tree-Paeonies force well in a greenhouse and there is much demand for those brought into flower in January. *K. Yashiroda, Japan.*

EXPERIMENTS ON THE CAUSE OF "POTATO SICKNESS."

FIELD observations carried out in south Lincolnshire since 1925 have shown that the two organisms Corticium (Rhizoctonia) Solani—a fungus, and the eelworm, Heterodera Schachtii, are invariably present on Potato plants exhibiting symptoms of the disease known to growers as "Potato Sickness."

It may be of interest to record here that although the disease is usually associated with fields which have been frequently cropped with Potatos—hence the name "Potato Sickness"—a bad case of similar crop failure came under observation in 1926, when a field of "old" pasture was freshly ploughed up (Fig. 66).*

In general, the whole of these field observations have indicated that Potato Sickness is a similar phenomenon to those of Clover Sickness and Greenhouse Soil Sickness, and is caused by plant parasites rather than starvation, or any accumulation of toxins in the soil.

In 1928, working in conjunction with Mr. E. Edwards—then Entomologist at Kirton Agricultural Institute—a series of pot experiments were set up in order to obtain some definite evidence as to the parts played by the fungus and the eelworm in causing this disease.

Soil was obtained from a Potato field of very bad record for "sickness" in the Boston area—a field where Potatos had been grown year after year for the past eighteen years, and the following series of pots were made up; five ten-inch flower pots being finally used in each series.

Series.		Inoculations.*
1.	Soil Sterilised†	Nil.
2.	,, ,,	Inoculated with the fungus, Corticium Solani.
3.	,, ,,	Inoculated with about 2,500 cysts of the eelworm, Heterodera Schachtii.
4.	,, ,,	Inoculated with the fungus and the eelworm (about 2,500 cysts).
5.	Unsterilised soil	Nil.

A small quantity of a mixture of inorganic artificial manure composed of three-parts sulphate of ammonia, four parts of superphosphate, and two parts of sulphate of potash, was applied in equal amount to each of the pots, and they were planted with a very susceptible variety of Potato—Eclipse, the "seed" being previously immersed in an 0·1 per cent. mercuric chloride solution for one-and-a-half hour to ensure the exclusion of Corticium Solani.

The pots were plunged in the soil of an isolated garden, and apart from occasional waterings were kept under field conditions.

The outcome of the experiments in 1928 was not altogether satisfactory; the reduction in growth of the plants receiving double inoculation (Series 4) being less than that of those grown in the untreated soil (Series 5), and there was little difference between the sterilised (Series 1) and those inoculated with Corticium Solani (Series 2).

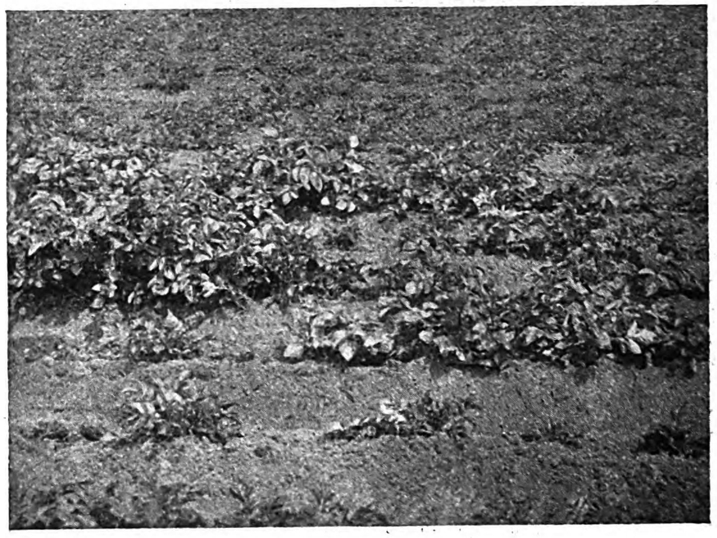

FIG. 66.—POTATO SICKNESS: EDGE OF A BAD PATCH IN FOREGROUND.

These results, together with a detailed account of the symptons of the disease were published by Mr. E. Edwards, since leaving Kirton, in the *Journal* of the Ministry of Agriculture, June, 1929 (q.v.). Following the experience of 1928, the plants were taken out of the pots and the soil replaced back in each pot. Very great care was taken to avoid any contamination of the soil of one series by that of another.

The pots were kept plunged in the same site outdoors during the following winter, 1928-29, and in the middle of March, 1929, additional inoculations of Corticium Solani were given to the soil of Series 2 and 4, while further inoculations of approximately equal numbers of eelworm cysts were given to Series 3 and 4.

The pots were again planted with "steeped seed" of Eclipse Potatos on April 15. No manure was applied to the soil.

The season was marked by its low temperature and lack of growing weather; conditions which field observations have shown to favour Potato Sickness.

The effect of the inoculations showed up well (Fig. 67), and throughout the growing period Series 1 showed a great increase in growth over all the others.

The "eelworm" Series 3, was better than Series 2, 4 and 5, at the commencement, but its growth gradually fell back until there was little difference between these Series at the end of May. The third week in June, the rate of growth of Series 3 was negligible, and finally, with one exception, the foliage turned completely yellow by the end of the first week in July, and within a few more days was dead.

The "fungus" Series 2, was at first much retarded, but tended to pick up towards the end of June, and then in great contrast to the "eelworm" Series 3, continued to grow and retain a perfectly healthy colour in the second week of July, despite the fact that the Corticium stage of the fungus was abundant at the base of the stems. (Fig. 70).

The "double inoculation" Series 4 was outstanding. It entirely failed to grow away and the little growth which was made turned yellow, wilted, and died towards the end of June. The mycelium of Rhizoctonia was much in evidence on the soil around the stems.

The "unsterilised" Series 5 showed a check in the very early stages—similar to that of the "fungus" Series 2, but it did not turn yellow and die away so early as the "eelworm" Series 3. The yellow coloration and death was quite eight or nine days later—the Corticium stage of the fungus being plentiful at the foot of the stems.

On the whole, its growth appeared to be slightly better than the "eelworm" Series 3, but markedly inferior to the "fungus" Series 2.

With such a small quantity of material available it was not possible to obtain any precise data to show the relative effects of the different inoculations on the growth rates.

In July the tops were cut off at ground level and the dry weights determined—by that time the "sterilised" Series 1 was becoming pot-bound. Nevertheless, the dry weights are interesting.

	Mean dry weight of four plants (growth above ground.)
"Sterilised" Series 1 ...	12·46 gms. ± 0·51
"Fungus" Series 2 ...	4·6 gms. ± 0·55
"Eelworm" Series 3 ...	4·45 gms. ± 0·92
"Double Inoculation" Series 4	1·58 gms. ± 0·16
"Unsterilised" Series 5	3·58 gms. ± 0·54

An estimation of the leaf area of an average plant from each series was made (using the "squared paper—proportional weight" method).

	Leaf Area.
"Sterilised" Series 1	1846
"Fungus" Series 2	646
"Eelworm" Series 3	450
"Double Inoculation" Series 4 ...	121
"Unsterilised" Series 5	327

---

* Only the fungus was observed in this case—not the eelworm. Similar crop failure occurred on control plots in bad areas of this field the following year.

* All the inoculations were carried out at the time of planting the tubers. The fungus was obtained the previous year from a diseased Potato stem, and had since been grown on Potato-mush agar. The inoculation was made by cutting out "squares" of fungus and agar, and placing them in the soil.

† Sterilised in an autoclave.

Summary.

Pots of soil obtained from Potato Sick land, and sterilised, were heavily inoculated in 1928 and 1929 with Corticium Solani and Heterodera Schachtii. They were planted each year with "steeped seed" of Eclipse Potatos and kept outdoors.

The Potato plants in 1929 failed to make much growth and died at the end of June showing identical symptoms to those of extreme cases of "Potato Sickness Disease," whereas a series of uninoculated controls (same soil) growing side by side made good growth and were quite normal.

Similarly two series, one inoculated with the eelworm only, and another solely with the fungus, failed to make as good growth as that of the control. In the case of the "eelworm" series the haulm turned yellow and died at the end of the first fortnight in July. The "fungus" series was a natural colour at that time. *W. F. Cheal, D.I.C., Kirton Agricultural Institute.*

MARKET FRUIT GARDEN.

Fruit trees and bushes withstood the long drought remarkably well. They began to show signs of suffering during July, which had less than half the average rainfall; but unsettled conditions arrived at the end of the month just in time to prevent serious harm. The only troubles which can be attributed to the drought are a considerable dropping of Plums and lack of size in some kinds of early Apples. The later varieties are particularly big for their present stage of development. Why the trees withstood the dry conditions so much better than they did last year can only be attributed to the fact that they had been much more heavily manured, particularly with nitrogenous fertilisers. They have made a great deal of growth, and would probably have become too rank had it been a wet season.

Black Currants.

The crop of Black Currants proved to be very heavy. The best plantations yielded two tons per acre, and over my total area of twelve acres I shall average more than 30 cwts. If frost had not taken a toll of the bloom of Boskoop Giant and Baldwin, the crop would have been still heavier. The fine weather was very favourable for picking, but trade was too bad to enable one to feel any enthusiasm about the result. Prices started at 8d. per lb. but very rapidly fell until the lowest point was reached at 2½d. At the time of writing, there is a slight rise, so some of the remaining Baldwins may raise the average; but I do not think it will amount to more than 3½d. or 4d. In my opinion Black Currants cannot be grown to sell at such prices. The bushes nowadays have a short life of usefulness, need generous manuring, and must be well cultivated. In addition, it is practically essential to spray in winter with tar-distillate to prevent aphis; and we are advised to spray also with lime-sulphur to control bud mite. Finally, it is an expensive crop to pick, and suitable non-returnable packages, which are now almost essential, are not bought for nothing.

If I were a specialist in soft fruits I should not despair of the crop. Such growers, by picking carefully and marketing in small packages, can generally realise better prices. The large grower, on the other hand, has to employ a big gang of indifferent pickers in order to get through the work, and can hope for nothing better than a sample fit for the jam factory. Really, I think that now is the time to grub old plantations and plant new ones. By the time the latter come into bearing the situation may have changed. For one thing, some of the continental growers will presumably have become tired of sending over fruit to sell at prices which cannot pay them; and a good many English growers will undoubtedly have given up the crop. In my own case, Black Currants are merely an intercrop between young fruit trees, and I have already started to grub half the acreage. The trees, which are of far more importance to me, will be better without the competition of the bushes. I shall grass down the land, and thus save the cost of cultivation. This will throw the trees into bearing and render them healthier, as it always does in my conditions. In one case, the Currants are under young trees of Cox's Orange Pippin, which are just going through the stage of cankering, which I always have to expect with this variety. Grassing down will assist greatly in overcoming this trouble; and the crop of Apples will be much more valuable than that of the Black Currants.

Apples.

Plums and Apples are very late in ripening By August Bank Holiday I am generally busy with both. This year I had no dessert Apples ready for the seaside markets, and Rivers' Early Prolific Plums were only just beginning to colour. This was really fortunate, because the thinning of Apples, interrupted by soft fruit picking, was not quite finished. The only Apples sold during July were Early Victoria, the largest of which realised 5s. 6d. to 7s. 6d. per half-bushel, which was very satisfactory. It is to be hoped that this marks the beginning of a season of good trade in Apples. In my opinion, this is the most profitable crop, although many growers would not agree with me. It is certainly the most pleasant to deal with. Unlike soft fruits, Apples do not lose condition if kept for a few days, and they lend themselves to a high degree of selection and grading.

Last winter several batches of worn-out Apple trees were severely headed down, the main branches being cut back hard to a lateral branch, where there was one, or to a spur. At the same time the spurs were thinned out. The success of this treatment in producing larger fruits is most marked. It is particularly striking in the case of some very weak trees of Lord Grosvenor and James Grieve. Not only is the crop worth much more than before, but the trees are carrying fine foliage and making plenty of growth. This treatment is probably called for at intervals with all varieties of the early Codlin type, which have a tendency to produce an over-crop of small fruits as they age. The work of thinning the crop is reduced if half the spurs are cut off, and the new laterals produced by this pruning can be used to make fresh spurs to replace older ones as time goes on. Manuring must be done as a further help towards rejuvenation.

Planting in Grass.

The success of nitrogenous manuring of trees in grass is so marked that I am going to try planting in grass next winter. This may be thought to be a mad idea, because it has been shown that nothing is more injurious to a young tree than allowing grass to grow close up to the stem. There are hundreds of examples about the country of failures from this cause. But all these are in the absence of proper manuring. I believe that, with the use of fertilisers right from the start, trees will grow away perfectly well in grass. My reason for trying this plan is as follows: The land to be planted is already occupied by trees in grass which will have to be grubbed. It is impossible to get out all the old roots. There are always enough left in to prevent subsoiling or even deep ploughing. Therefore I shall disturb the turf as little as possible and plant in it. Possibly a space round each tree will be kept clean for a year, but after that the grass will be allowed to encroach. I am not making this experiment in the dark. I know one excellent grower who has cut down woodland, without grubbing the roots, and has dotted fruit trees about whereever possible between the stumps; and they are doing very well. In this case the grass is kept down by sheep, and any rough stuff remaining is burnt off in early spring. I have also examples on my own place of young trees planted in the grass orchards to fill gaps. These are going ahead well now that the manuring is right.

If such an experiment succeeds it opens up great possibilities. It means that one could buy cheap pasture land and plant it right away without breaking up the grass. It would not be possible to intercrop with bush fruits, of course, but there would be ample compensation for this in the low cost of cultivation. There are, of course, plenty of examples, in Kent and elsewhere, of fine orchards planted in grass; but these have generally had a space cultivated round each tree for a good many years. My point is that manuring can take the place of all cultivation, the only use of which is to supply nitrogen. The old idea that cultivation is necessary to conserve moisture is refuted by the appearance of properly manured grass orchards in a season such as this. I have not the slightest doubt that, where the grass is mown annually and used as a mulch, there is more moisture underneath than there is in cultivated land.

Dwarf Trees.

Going to the other extreme, I am planning a small plantation of Apples, mainly Cox's Orange Pippin, on Paradise No. IX. In this case no experimental risks will be run. The land is being summer fallowed to clean it, and it will be kept under clean cultivation. The idea of the dwarf trees which this stock produces is very attractive. They come into bearing about three years after planting, and carry fruits of very fine size and quality. This is obviously the stock for temporary filler trees in commercial plantations, provided that rabbits can be kept out.

Bacterial Canker of Plums.

The disease recently named bacterial canker of Plums and Cherries is very troublesome this season. I have it in the familiar "shothole" form on the leaves of Rivers' Early Prolific Plums, which will probably be almost entirely defoliated. The disease is also the cause of much dead wood in Plum plantations. The affected branches can be detected now by the yellowing and wilting of the leaves. A neighbour has the disease badly among Morello Cherries grown in bush form. He has cut out the affected wood several times this season, but now a good many of the trees are dying right out. *Market Grower.*

REMARKS ON THE CONDITIONS OF THE FRUIT CROPS.

(See Tables and Summaries, Ante pp. 112-118.)

SCOTLAND, N.

Sutherlandshire. After the very dry spring it is remarkable to find the crops looking so well. Reports of the crops in this district are almost identical with those of Dunrobin, where, with the exception of Apples, fruit crops promise well. Pear blossom set freely, as did all varieties of Plums and Cherries. Gooseberries, Raspberries, Loganberries, Black and Red Currants, together with the Veitchberry, show excellent crops, although the last-named does not ripen its fruits too well here in the north. Strawberries flowered well and promise a very heavy crop, the latest variety we grow, Elton Pine, was just passing out of flower at the time of this report, July 6. The soil here is of a light, sandy texture overlying a bed of pure sand. *W. F. Game, Dunrobin Castle Gardens, Golspie.*

SCOTLAND, S.E.

Roxburghshire.—The dry weather acted a a severe check on fruit crops in general. Damsons are a very heavy crop on old trees, and the fruits are likely to be of average size. Strawberries failed to swell properly owing to the drought. The soil here is heavy in patches, with some of a gravelly nature. *Alexander Black, Ancrum House Gardens, Ancrum.*

SCOTLAND, E.

Aberdeenshire.—All crops are more encouraging than last season. Fire blight is rather widespread on both wall and bush Apple trees. The weather in January and February was very severe, with the result that young trees received a severe check, and a few of these are now showing signs of canker. Pears and most stone fruits, unless protected when in flower, are unsatisfactory in this district. *Andrew McLeod, Cluny Castle, Monymusk.*

—— All small fruits are very good and much above the average, but Apples are very bad; the wall trees are carrying fair crops, but bush and standard trees are a complete failure. The soil here is of a light, peaty nature over a very hard pan. *William Smith, Dunecht Gardens, Aberdeen.*

Banffshire.—Plums suffered very badly from late frosts and unfavourable weather when they were in bloom, while Pears are never a dependable crop in this district. The Strawberry plants suffered badly during the winter, when the severe frosts almost denuded most of the plants of their foliage, but they have borne wonderful crops, although still weakly in foliage. *Archibald Cathie, Aberlour House Gardens, Aberlour.*

Fifeshire.—The fruit crops in general are looking well. Small fruits especially are a heavy crop, and Strawberries are a better crop than last season. Apples, Pears and Plums in the gardens here are suffering from last season's excessive flowering. *William Grieve, Balfour Gardens, Markinch.*

—— Small fruits in general are plentiful, but the crops on the trees are under the average, owing to frosts at flowering time. In this district the soil is of a light nature with a sandy subsoil. *Patrick Hunt, Falkland Palace Gardens, Falkland.*

Forfarshire.—The fruit trees and bushes suffered severely from the heavy spring frosts, and owing to this the crops are on the light side. Black Currants and Strawberries are an average crop, but Red Currants and Gooseberries are very patchy. Gooseberry mildew is not much in evidence so far; it is usually held in check here by applications of fine lime dusted over the bushes when damp; we find this is as good a remedy as any, and very easily applied. Blackberries were badly damaged with frost, most of the fruiting wood being absolutely killed. Aphis is very scarce so far. *J. B. Peffers, Panmure Gardens, Carnoustie.*

Midlothian.—The reliable varieties of Apples are bearing fine, clean crops, but special mention should be made of the old Lord Grosvenor trees, which are practically overladen with fruits; the " set " of four fruits to each spur is numerous; but five and even six fruits per spur were noted; so that a good deal of thinning will require to be done. A comparatively young Apricot tree on a south wall is carrying a very fine crop of good-sized fruits, and it should be stated that this tree, so far, has never failed to supply fruits each year. An old Peach tree which, although it does not cover a very large wall space, is quite healthy, and is carrying a fair crop of fruits, Numerous Cherry fruits have dropped, no doubt owing to the prolonged spell of very dry weather throughout May and June. Among the varieties of Strawberries, The Duke and Sir Joseph Paxton are vigorous and very healthy, while the two-year-old plants of the last-named are also fruiting well. *David Armstrong, The Drum Gardens, Gilmerton.*

Perthshire.—Apples are an average crop and promise well, but Pears were spoiled, during the flowering period, by late frosts. Small fruits are good, Black Currants exceptionally so, and Strawberries are a moderate crop. The soil here is a light loam over a gravelly subsoil. *William Taylor, Meikleour Gardens, Meikleour.*

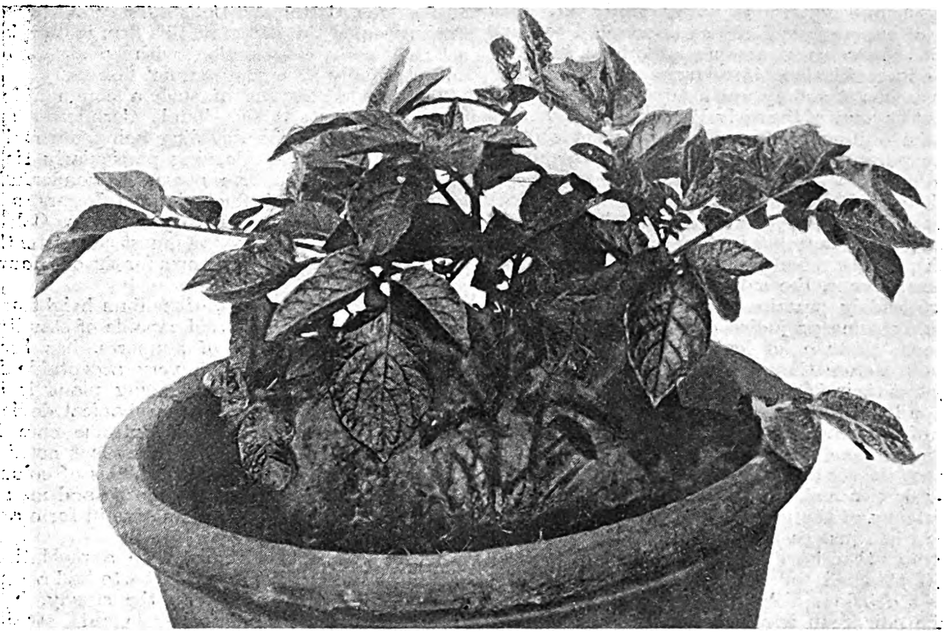

FIG. 71.—POTATO SICKNESS.

" Fungus " Series 2 (from Fig. 69) showing Corticium at the base of the stems.

SCOTLAND, W.

Argyllshire.—Owing to the late frosts, a considerable amount of damage was done to the fruit blossoms generally, and especially Apples and Pears. The soil in this district is very wet and heavy. *E. Ferguson, Appin House Gardens, Appin.*

Buteshire.—The cold weather during the late spring interfered with the setting of the later-flowering fruits, such as Plums, Pears and Apples, while bush fruits seem to have escaped the cold winds and are very good for the season. Strawberries, owing to disease, seem to be getting worse every year; some of the plants are quite good while others are dwindling away. The soil is a heavy loam on marl rock and remains very wet and cold. *John J. Davidson, Ardencraig Gardens, Rothesay.*

Dumbartonshire.—All small fruits have produced good crops. Strawberries, which appeared severely affected by the severe winter, being in some cases almost completely defoliated, made a wonderful recovery. Fruit trees generally have been more than usually free from attacks by the caterpillars of the Winter and March moths, doubtless also owing to the severe winter. For the second season in succession, Apple trees are carrying good crops. Pears and Plums are more or less poor. The soil here is of a peaty nature and shallow in places, overlying rock. *F. A. Bush, Arddarroch Gardens, Garelochhead.*

Dumfriesshire.—Small fruit crops are over the average, especially Black Currants and Gooseberries, but in some gardens the latter are badly affected with American blight. Strawberries are a good crop and the fruits are of good flavour, although not so large as they should be. Apple trees blossomed freely but the fruits did not set well. Plums are very good in quality and the crop an average one. Cherries looked fairly well for a time, but many of them dropped. The soil here is a light, sandy loam. *James McDonald, Muirhousehead, Lockerbie.*

ENGLAND, N.E.

Durham.—All fruit trees promised good crops in early spring, but Pears and Plums did not set well, as there was a long spell of cold, north-east winds when they were in full flower. Some varieties of Apples are carrying very good crops, notably Lane's Prince Albert, Bramley's Seedling, Allington Pippin and small trees of Lord Lambourne. Strawberries were an average crop but the fruits were very small. Gooseberries and Black and Red Currants have carried heavy crops, the fruits being large and clean. Small fruits ripened much earlier this year than usual. The soil here is of a very heavy nature on a clay subsoil. *J. H. Yarrow, Wynyard Park Gardens, Stockton-on-Tees.*

Northumberlandshire.—The late spring and frosts at night until well into April, had the effect of retarding the flowering of fruit trees, with the result that there was a good set of fruits of Plums, Apples and small fruits, although the continued drought affected the Strawberry crop. Blackberries, Gooseberries, Plums and Apples are excellent and the last two will require to be well thinned. Heavy rain on July 5 (1·23 inch) benefited all crops considerably. *J. Winder, Howden Dene Gardens, Corbridge-on-Tyne.*

Yorkshire.—The fruits in general are very satisfactory, bush fruits especially, Black Currants and Gooseberries bearing very good crops. Strawberries also are a very good crop, thanks to early mulching. Pears are a failure, although they blossomed well, but the flowers were too early. Bramley's Seedling is again one of the best Apples, while the varieties Ribston Pippin, Edward VII and Newton Wonder are fairly good. The soil in these gardens is a thin loam, resting on chalk, and the gardens are situated ninety feet above sea-level. *J. Turton, Sowerby House Gardens, Bridlington.*

(*To be continued*).

VEGETABLE GARDEN.

MAIZE.

It is said that the cultivation of Maize—Zea Mays—as a food plant can be traced back to the time of Homer, and its importance as a source of food for man's sustenance is probably second only to that of Rice. It would be without interest to consider here the numerous purposes to which this most valuable plant is put, when in a dried state, in tropical and sub-tropical regions, but it may be noted that so long as sixty years ago its possibility as a cereal crop in this country was discussed and it was then considered that by selection and acclimatisation a strain could be produced which would ripen grain in our climate and become a standard crop.

This hope does not seem to have materialised, but at about the same time it was sought to popularise the manner of eating Maize, so common in the United States of America, as Green Corn, and there can be little doubt that this led to a vast improvement in varieties suitable for this purpose under our climatic conditions.

The addition of a table vegetable of this delicious and nutritious nature and yet, for want of experience of the sorts adapted to our climate, so strangely unappreciated here, seemed of no inconsiderable importance, the more so as its season of supply was autumn, reproducing the lost flavours of the early Peas and Asparagus. But the ordinary yellow Maize was not suited to the purpose and, apart from early ripening, other conditions had to be fulfilled before it could hold its own as a popular vegetable.

But although there is now no lack of good varieties very suitable for our English climate, which produce medium-sized cobs of sweet and delicate flavour, the cultivation of the plant is not so widely practised as its merits deserve. Probably some prejudice exists because of the common mistake of gathering and cooking the cobs before they are sufficiently developed to perfect their flavour; on the other hand, if left too long, that succulent tenderness reminiscent of Asparagus has departed. Admittedly, it requires some judgment to ascertain the exact time to take the ears as Green Corn for the table; a day or two makes considerable change in the consistency of the grain. The cobs are at their prime when just passing out of the milky state; the grains then have firmness but not hardness, and if steamed for fifteen or twenty minutes make a delicious dish. But although this may be the epicurean way of serving green Maize, it is not the only way; all the uses made of Peas for soups and stews are common to it, and in a riper stage the ears may be roasted and served like Yams or Potatos. In America and the continent of Europe the immature cobs are used instead of Gherkins, for pickling.

With the dwarf-growing and quickly-maturing varieties available to-day the area of possible cultivation is a very extended one. In the southern counties supplies may be available from the end of July onwards, and in the midlands from early August; farther north, cropping may be less certain, except in favoured localities, but it would be interesting to know from readers of *The Gardeners' Chronicle* how far north the plant has been successfully cropped. Under favourable conditions in the south it is possible to sow out-of-doors at the end of April and gather serviceable cobs by the beginning of August, but it is generally wise to raise plants in gentle heat during April and plant out so soon as practicable in May, and in this direction my experience is that considerable advantage accrues from sowing the seeds singly in three-inch pots rather than in boxes; the plants then receive much less check than if transplanted from boxes, and if inclement weather conditions prevail when they should be planted out it is not difficult to move them into slightly larger pots and keep them growing until it is practicable to plant out.

It may be noted, however, that the plant suffers more from cold winds than from morning frosts, and considerable protection can be provided for plants raised indoors, by planting between rows of early Peas, which give protection in the early stage, but are removed and leave the Maize exposed when warmer weather is assured. The risk of young plants suffering in early spring is common to other vegetable crops, and a little protection obviates this.

It must also be borne in mind that the plant luxuriates in the rich, alluvial valleys of tropical countries and therefore loves heat and moisture; the heat naturally depends on the season, but moisture can be largely provided by previous preparation, and on sandy soils of low water-holding capacity, it is good practice to plant in shallow trenches liberally supplied with organic manure. These trenches retain the moisture from casual showers, facilitate artificial watering when necessary, and may be gradually filled in later in the season. This attention is no greater than that given to Peas and other vegetable crops, and is well repaid in the assurance of the supply of a highly nutritious table delicacy. *W. Auton.*

NURSERY NOTES.

MESSRS. JAMES CARTER AND CO.

A pleasant hour or so spent in the grounds of Messrs. Jas. Carter and Co.'s nursery at Raynes Park revealed the fact that this firm is carrying on the work of selection with great vigour and especially so among annual flowers.

The selected strains of such a common but popular subject as the double Cornflower are remarkably fine, the doubling being unusually good and the blue colouring particularly rich. In Calendulas, this firm possesses wonderfully brilliant strains with finely-formed flowers, and this is of special interest to growers as Calendulas are now among the most consistently popular of annual flowers grown for the cut flower market.

A strain of Salpiglossis, of medium height and branching habit, sturdy and capable of standing erect, without the aid of supports, has been evolved and should prove very acceptable in these days when a labour-saving plant is as desirable as a labour-saving mechanical device.

Nemesias give evidence of extreme care in selection as regards habit, and they lack nothing in respect of brilliant and soft shades of colour. The Stocks are very fine, the crimson and mauve varieties being unusually attractive in form and colour.

The branching Larkspurs were a revelation, and although the writer has hitherto had a very low regard for these flowers, the sturdy, free-branching and exquisitely-coloured strains at Raynes Park entirely altered the point of view and created a "most favourable impression," together with a determination to grow these flowers in the future. Viscaria Loyalty, and the splendid heads of the large Hyacinth-flowered Candytufts were arrestingly beautiful and of the latter we have never seen a finer strain.

Although they are not annual flowers, the Antirrhinum permit no one to pass them without respect, while most visitors are filled with admiration for such fine sorts as Carter's strain of Nelrose—a trifle dwarfer and deeper in colour than the original form; Beacon, Cottage Maid, Queen of the North, His Excellency, Carmine King, Victory, Prima Donna—a lovely fawn pink; Golden Monarch, Sparkler, Fiery Bell and Scarlet Flame. All these were represented by goodly breadths, thus displaying their good qualities in convincing fashion to those who desire Antirrhinums for any garden purpose whatever.

Quite naturally, the firm that holds an unique historical record in regard to Sweet Peas, and—in the person of Mr. Harold Beale—is supplying the President of the National Sweet Pea Society for the current year, devotes considerable attention to the most popular of all hardy annual flowers. The tail end of a long spell of hot weather was not the best time to inspect Sweet Peas, nevertheless the extensive trials at Raynes Park were worth inspection because they are well grown and the outdoor as well as indoor plants carried abundance of excellent flowers. All the popular varieties and many novelties are grown extensively and several new seedlings added interest to the Sweet Pea section of the nursery. Of, as yet, unnamed sorts we were attracted by a good scarlet of the Mammoth type, a pretty blue variety, several with double standards, and one already named, Shot Silk, pale blue, with pink in the standards. Messrs. Jas. Carter and Co. believe that Sweet Peas with double standards will become popular and their faith is shown in the numerous colour selections they possess of the Fluffy Ruffles type.

HOME CORRESPONDENCE.

[*The Editors do not hold themselves responsible for the opinions expressed by correspondents.*]

The Effects of the Drought.—I was recently shown over an orchard in which Lane's Prince Albert and Cox's Orange Pippin were two of the principal Apples grown, and it was most remarkable to see how these two varieties were behaving under the dry conditions. The trees were growing in a grass orchard stocked with poultry. Lane's Prince Albert was bearing a heavy crop of clean fruits, with foliage of full size, and was in perfect condition. On the other hand, Cox's Orange Pippin was bearing a very light crop, and the bushes were almost leafless. They were afforded the same cultural conditions in every respect, yet the one appeared to be in perfect health, while the other appeared to be anything but happy. It is very sad, but it tends to show how susceptible Cox's Orange Pippin Apple is to extreme conditions. In our grass orchard here, Cox's Orange Pippin in standard form has suffered severely, while in the same plot Worcester Pearmain is bearing a heavy crop and showing very little signs of the drought. Cox's Orange Pippin in bush form on cultivated ground is in perfect health, the foliage is dark green, and the leader growths have attained a length of eighteen inches, which emphasises the value of soil cultivation. The same results are borne out again in other plots, with Worcester Pearmain grown in grass, and grown in cultivated ground. The former trees have dropped most of their fruits, and the foliage is a sickly, pale colour; whereas the trees on the cultivated ground have retained their fruits—a very fair crop—and the foliage is dark green in colour. *H. H. Cook, Horticultural Department, Reading University.*

Three Lovely Blue Annuals.—In spite of the continued drought, these annuals have excelled—and made lovely edgings in the borders reserved for cutting purposes. They were simply sown thinly in shallow drills in April, and have continued in flower to date:—Anagallis, large-flowered, blue; grows about six inches in height, and is a compact, very free-flowering plant. Phacelia campanularia, a lovely shade of blue, with bell-shaped flowers; it grows about nine inches high and makes a charming picture. Viscaria Blue Bird, also very free-flowering, and making a most compact plant about nine inches in height. The colour is slightly paler than in either the foregoing, but the plant is covered with flowers and remains in bloom a long time. On our gravelly soil these three annuals have proved real treasures this season. *G. H. Emmett, Taplow.*

The Future of Strawberries.—There is something cheerfully optimistic in the remarks made about the future of Strawberry growing in the leading article on page 101, and everyone interested will join in the hope that in a few years time the cultivation of Strawberries will not be "the difficult and exasperatingly disappointing task" it has been of late. At the same time, while they hope for the best, many growers have their doubts, and their experience this season has not tended to make them look very cheerfully into the future of Strawberry culture. It is very unfortunate that while the demand for fresh Strawberries has increased, the supplies are not forthcoming, and there must be thousands of people in the country who have not tasted Strawberries this summer, for the simple reason that they could not afford to buy them. I have not seen a single Strawberry offered retail at less than a shilling a pound—and poor samples at that—which means that Strawberries are beyond the reach of a big proportion of the population who used to indulge in the fruit when it was plentiful. What is wanted is more Strawberries, so that the public can buy them at prices they can afford to pay, and it is most undesirable in the interests of both producers and consumers that Strawberries should ever become a luxury fruit, like hot-house Grapes and Peaches. This, however, is what things are coming to very rapidly, and at the moment the future of commercial Strawberry growing seems to be hanging in the balance. In view of this disappointing state of affairs the whole community has good reason to hope that *The Gardeners' Chronicle* will prove to be a true prophet. *G. H. Hollingworth.*

Allium triquetrum.—I agree with all Mr. Arnott states of this species (p. 29, July 13), except the time of flowering. In Bentham and Hooker's *British Flora*, its distribution is given as "In damp, shady places in the Mediterranean region (of Europe) from Spain to Greece." Here, in Cornwall, it grows commonly, but locally, on hedgebanks and the grassy sides of roads, and on the edges of woods, and commences to flower in April, by the end of which month it is well out, and looks, at some distance, like white Bluebells, the green streaks down the middle of each segment of the perianth being separately invisible and serving to make the flowers appear more numerous and narrower that they really are. This species is included in the "Index Expurgatorius" of the present issue of the *Gardeners' Year Book* (p. 278), as to be used with caution. No doubt it spreads easily by means of its seeds and the multiplication of bulbs, but if the former are cut off so soon as the stems fall over, it should not be troublesome. I believe Mr. Arnott writes from somewhere in Scotland, which may account for the later flowering of the plant with him. *C. Nicholson.*

FOREIGN CORRESPONDENCE.

GYMNADENIA RUPESTRIS.

Undoubtedly, Gymnadenia rupestris is one of the loveliest of the tiny Orchids to be found growing in the crevices, or on rocks, shallowly covered with soil, in the woods of middle and northern Japan. The leaves are dark green, somewhat thick, and lanceolate, with several dark reddish-purple, longitudinal lines on the under surface. It usually produces three or four leaves on a stem attaining four to six inches in length. The lower part of the stem is dark reddish-purple, lighting towards the upper, on which dark reddish-purple stripes and dots are present.

When grown on the margin of the shady bog, G. rupestris attains a height of nine inches or more, and produces several very long, lanceolate leaves, and its graceful appearance is then lost. It bears five to thirteen or more flowers, loosely clustered, and of a lovely, soft, pinkish-purple colour, fading towards the spur, which is slightly pointed, and being darkest on the three-parted lip; the spur is twice as long as the lip.

A compost of two parts loam and one part coarse sand, adding a little peat, is most suitable. Fill one-fourth of a five-inch pot with crocks, and the remainder with compost, placing five tubers just beneath the soil level. Watering should be done sparingly, for if the compost is left in a state of saturation, grossness of growth will result. If long-stemmed plants are desired, some Sphagnum-moss should be scattered, at the time of potting, on the crocks; this will retain and always ensure ample moisture at the roots. G. rupestris loves light shade, but resents overcrowding. The cut-worm and other pests are very fond of the young plants; several times I have lost whole specimen plants in a single night. It flowers during June and July.

The genus Gymnadenia, which is closely related to Habenaria, deserves more attention, particularly this species. *K. Yashiroda, Japan.*

SOCIETIES.

BAKEWELL SHOW.

August 8.—The Bakewell Farmers' Club is a well-known institution, and the prizes offered at its annual exhibition have attracted the finest cattle, horses, pigs, sheep, and poultry from the whole of the Peak district, and also from far-distant counties, until the event has become one of the most popular of its kind in the Midlands and one whose awards are highly prized among agriculturists.

A few years ago a horticultural section was added and at once it proved a splendid additional attraction to the many thousands of people who attend and many of whom come from distant places by rail and road. This section has increased in extent and quality, and this year two big tents were needed to house the competitive and non-competitive exhibits; one of these was 200 feet by 50 feet and the other 205 feet by 85 feet.

Lieut.-Col. H. K. Stephenson of Hassop Hall, Bakewell, is the President for 1929 and Mr. U. Roland Burke, agent to the Duke of Devonshire at Chatsworth, is Director of the whole show—agricultural and horticultural; while Mr. A. W. Coakes, Chatsworth Estate Office, and Mr. W. Keetley, Bakewell, are the able Hon. Secretaries, and Mr. J. G. Weston, of Chatsworth Gardens, and Mr. H. W. Hards, act as Hon. Managers of this part of the Show.

Trade displays were uncommonly good, Mr. J. C. Allgrove's fruits, Messrs. Dobbie and Co.'s Dahlias, Messrs. Jas. Carter and Co.'s vegetables and Messrs. Alex. Dickson and Son's Roses being especially attractive.

Judging commenced at 8.30 a.m., and so soon as the judges had finished their work in the larger tent, the waiting thousands thronged in. Judging was concluded in the smaller tent by about 11 a.m., and three or four minutes later the tent was packed from end to end with visitors.

Half-a-dozen important open classes are provided and very handsome cash prizes offered—£126 in all, but as competition was very keen additional prizes were awarded, increasing this sum very materially.

There were two collections of hardy perennial flowers arranged on a space not exceeding thirty feet by ten feet; the collections were arranged on the ground level and made an effective display. The first prize of £12 was won by Messrs. W. Artindale and Son, Sheffield, who had a long, slightly curved, border-like display in which Gladioli, Bocconia cordata, Alströmerias, Heleniums and Kniphofias figured boldly. Second prize fell to the Gayborder Nurseries, Melbourne, for a square arrangement that was admirably finished off and contained good examples of Kniphofias, various Liliums, Echinops, Gladioli, Carnations and Solidagos.

Only one exhibitor came forward in the class for a collection of cut Roses occupying a space twenty feet by five feet; this was Messrs. Barron and Son of Barrowash, who contributed a bold display of flowers arranged in pillars and baskets and were awarded the first prize.

The £10 offered as first prize for a collection of Sweet Peas was won by Messrs. E. Leigh and Son, Stoke-on-Trent, with fine flowers of Pinkie, Valetta, Mrs. A. Searles, Gold Crest, Mammoth, Powerscourt, Magnet and other good sorts, arranged on a space twelve feet by five feet; second Mr. J. Haycock, Gyfelia, Wrexham; third, Mr. J. Wilcox, Mansfield.

Mr. J. Haycock had his revenge, however, in the open class for a dozen bunches of Sweet Peas, distinct, winning the premier award with excellent flowers of Olympia, Pinkie, Youth, Magnet, Powerscourt, Model, Valetta, What Joy, Mammoth, Mrs. Horace Wright and Royal Mauve; second, Messrs. E. Leigh and Son.

Four entries, all good, were made in the attractive class for a decorated table of fruits, to include eighteen dishes representing not fewer than eight distinct kinds. The handsome sum of £20 was offered as first prize and this was won by Messrs. Brook, Bray and Son, who showed good black and white Grapes, Peaches, Nectarines, Apples, Pears, Gooseberries, Melons, Cherries and Raspberries; second, Mrs. Walter Evans (gr. Mr. J. Maxfield), Derby; third, Lord Belper, Kingston Hall, Derby; fourth, Lord Leconfield (gr. Mr. F. Streeter), Petworth Park, Sussex. The schedule only allowed for two prizes, but third and fourth awards were added by the Committee at the request of the judges.

The most astonishingly fine competition was found in the last of the open classes. The schedule demanded a comprehensive display of vegetables (arrangement to be left to the discretion of the exhibitor), to occupy a space not exceeding 120 square feet of tabling, and offered two prizes, one of £20 and one of £10. Two competitors came forward and each was provided with an end space in the central portion of the larger tent; they were Mr. A. Falconer, gardener at the Cheadle Royal Hospital and Mr. F. Streeter, gardener to Lord Leconfield at Petworth Park, Sussex—both well-known contributors to *The Gardeners' Chronicle*, and each owning a well-deserved reputation as a skilful cultivator and exhibitor. It was a very fine battle between these two, and their displays alone were worth travelling some hundreds of miles to see. The Cheadle Royal exhibit won the premier award; it appeared to be rather larger and better filled than the one from Petworth, and Mr. Falconer would be the first to admit that he had some advantage in living nearer Bakewell than his competitor. His Potatos, Celery, Runner Beans, Leeks, Tomatos, Beets, Onions, Lettuces, Cauliflowers and Endives were splendid and his general arrangement at once bold and attractive. Mr. Streeter's effort was scarcely less attractive but he needed "more weight" in his background to compete successfully against Mr. Falconer; he showed excellent Premier Onions, Aubergines, salad material in great variety, Beets and Tomatos, while his Carrots and Parsnips were exquisitely symmetrical and clean, and much superior to those in the premier collection. We offer our heartiest congratulations to each competitor for the grand displays they staged in one of the finest competitions it has been our good fortune to witness.

In the other sections of the show there were many fine exhibits. Mr. Haycock won the Challenge Cup offered by Mr. J. Cyril Lockwood for the best nine vases of Sweet Peas; Mr. Roland Burke and Mr. J. J. Kay, both of Bakewell, were second and third respectively. Mr. Haycock was also first prize-winner for six vases of Sweet Peas, followed by Mr. H. E. Welch, Belper, and Mr. S. Tinsley, Ashford, Bakewell. Mr. Welch, however, scored heavily in the single vase classes, where special colours were required. He won with Model, Pinkie, Powerscourt, Olympia and Gorgeous in fairly close competition.

Mr. Roland Burke showed the best collection of "cut garden flowers" with a bright display in which finely-grown annuals were a feature; the R.H.S. Banksian Medal was also awarded as this was considered the best exhibit in sections B and C. There were eight competitors and as each one filled a space six feet by three feet it will be obvious that the combined display was particularly good. The President, Lt.-Col. H. K. Stephenson, Hassop Hall, Bakewell, won the second prize.

Mr. J. Cyril Lockwood, Ranmoor, Sheffield—of "Brighter Sheffield" fame—was a successful competitor, winning first prizes for six bunches of outdoor flowers, for six vases of Annuals—a grand lot, in which Larkspurs, Calendulas, Nemesias, Stocks and Candytufts were finely shown; for a glass vase of flowers artistically arranged; and for several other items.

Other leading prize-winners included Mr. Stanley Orme, Mrs. McCreagh, Mr. R. Flint, Mr. E. L. Hoyle, Mr. W. E. Ann, Mrs. Storrs Fox, Mrs. Walter Evans, A. Preston Jones, Esq. (gr. Mr. J. Bacon), Mickleover; L. A. Clowes, Esq. (gr. Mr. J. Hammond), Ashbourne; and Mr. J. H. Hopkinson, Clay Cross.

Medal Awards to Trade Displays.

Large Gold Medals.—To Mr. J. C. Allgrove, for fruit trees and picked fruits; to Messrs. Jas. Carter and Co., for a display of vegetables; to Messrs. John Peed and Son, for stove and greenhouse plants; to Messrs. Alex. Dickson and Sons, for Roses; to Messrs. Dobbie and Co., for a grand lot of Dahlias; and to Mr. T. Robinson for Roses.

Gold Medals.—To Messrs. Backhouse's Nurseries, Ltd., for a rock garden; to Messrs. Brook, Bray and Son, for floral designs; to Messrs. Daniels Bros., Norwich, for Gladioli and Phloxes; to Messrs. Dickson, Brown and Tait, for Gladioli; to Messrs. Dickson and Robinson, for Hydrangeas; to Messrs. C. Englemann, Ltd., for Carnations; to Messrs. E. F. Fairbairn and Sons, for Phloxes; to Messrs. W. Lowe and Son, for Roses; to Messrs. R. W. Proctor and Sons, for Roses; to Messrs. W. H. Simpson and Sons, for Phloxes.

Silver-Gilt Medals.—To Messrs. Barron and Sons, for rock and water garden; to Messrs. Blackmore and Langdon, for Phloxes and Begonias; to Mr. Alfred Dawkins, for Gladioli; to Messrs. Dicksons, Ltd., for Roses; to Messrs. John Forbes, Ltd., for Pentstemons; to Messrs. Hewitt and Co., for Roses; to Messrs. Pennell and Co., for hardy flowers; to Messrs. Maxwell and Beale, for a rock garden; to Mr. Stephen Sims, for a rock garden.

Silver Medal.—To Messrs. Wheatcroft Bros., for Roses.

SCOTTISH NATIONAL SWEET PEA, ROSE AND CARNATION.

August 7 and 8.—In respect to the number of entries and the attendance of the public the annual show held in Kelvin Hall, Glasgow, was the largest and most successful in the history of the above Society. The opening ceremony was performed by Lady Wilson, Invertrossachs, and in proposing a vote of thanks Mr. William Cuthbertson declared that the show of Sweet Peas would rank as the finest in Britain if not of the world and he also praised the system on which the seedling trials were conducted. In his opinion the final adjudication which took the form of judging the varieties when bunched, was helpful in determining the true colour tones of the flowers.

There were 152 classes scheduled and except in a few instances they were well filled, something like 1,500 vases being staged in the Sweet Pea section alone. A desirable improvement was introduced in the lay-out by arranging the decorated tables, interspersed with Palms, in the centre of the hall and flanking them by tables containing the competitive and trade exhibits.

In the open classes for Sweet Peas Mr. John A. Grigor, Banff, defeated Messrs. Torrance and Hopkins, Busby, and Mr. David Smith, Cummock, in the competition for twenty-four vases; Improved Daisybud, Picture, Grenadier, Charming, Magnet, Pinkie and Mrs. Searles were prominent in his set. He also scored for six vases containing novelties of 1929. These consisted of well-grown blooms of Treasure, Valetta, Vectis, Blue Bell, Flamingo and Idyl.

Mr. F. Dunbar, Kilmahew, Cardross, showed the best of twelve vases, and the runners-up were Mr. Alex. Barthwick, Glenoran, Helensburgh, and Mr. J. M. Urquhart, Castle Gardens, Roseneath.

The principal prize-winners in the Gardeners' Classes were:—Mr. Robert Findlay, Invergare, Rhu (12 vases); Mr. Charles Glass, Bloomhill, Cardross (nine vases); Mr. Arthur Godfrey, Artarman Gardens, Rhu (six vases); and Mr. John Genge, Whitehouse Gardens, Helensburgh (three vases).

The Burpee Cup for twelve vases Sweet Peas secured a large entry, and keen competition was experienced. The trophy was won by John R. Paterson, Alloa, whose exhibit was notable for the fresh and clean appearance of the flowers, which included excellent specimens of Charming, Grenadier, Powerscourt, Chieftain and Sybil Henshaw.

The Claud Allan Cup for six vases was awarded to Robert Findlay, Rhu, while the best vase of any 1928-9 variety was Flamingo, shown by Mr. George Ballingal, Dumbarton, and Mr. James Paul's vase of Powerscourt was adjudged to be the best vase of Sweet Peas in the show.

Roses were strongly represented in the open section. Here Messrs. D. and W. Croll put up a representative collection which was outstanding in its artistic arrangement. In this first prize exhibit Else Poulsen, Mrs. Barraclough, Angele Pernet and Shot Silk were prominent. Messrs. Thos. Smith and Son, Stranraer, and Mr. C. Ferguson, Dunfermline, were placed second and third. Basket classes occupied a large space on two sides of the central table and while the display as a whole was the best seen at a Glasgow Show, the blooms bore evidence of the previous day's rainfall. Mr. R. Ferguson defeated Mr. William Ferguson, in the class for twelve baskets, but the positions were reversed in the class for six baskets. Cleaner flowers were submitted in the class for three vases by Messrs. D. and W. Croll, who were successful with a fine trio composed of Margaret McGredy, Miss Henry Bowles and Mrs. Barraclough. Very few points separated the winning lot from those of Messrs. Adam and Craigmile, who, however, scored heavily in the two succeeding classes for forty-eight and twenty-four blooms. The former group contained a bloom of the pink variety Anne, which received the special award for the best Rose in the show. The Messrs. Croll who were second, were recompensed by their success in the class for twelve blooms. Mr. William Ferguson had the superior flowers in three of the six classes for twelve blooms of one colour, viz., pink (Mrs. Henry Bowles), red (Earl Haig) and white (Frau Karl Druschki). Messrs. D. and W. Croll excelled in the cream and any other colour classes with Mrs. Lamplough and Lady Inchiquin, while Mabel Morse exhibited by Mr. W. Ferguson was the best in the yellow class.

The Cup presented by Mrs. Arthur, Rosemount, Monkton, for the best amateur entry of twelve blooms, was won outright by Mr. James Paterson, Lamington, who also provided the best bloom in the amateur section.

Keen rivalry prevailed in the Carnation section where the exhibits reached a high standard of excellence. Mr. Alexander McMillan, Cumnock, who won first prize in all four classes for six vases in the open competition for border varieties, had eight first prizes and three second prizes to his credit and these carried with them the Carlaw and Irvine Valley Cups. The Woolman Gold Medal and the Secker Silver Medal went to Mr. J. H. McDonald, Glasgow, and other names prominent in the prize list were: Mr. John Macfarlane, Airdrie; Messrs. Torrance and Hopkins, Busby; Mr. James Smith, Darvel; Mr. Alex. Dalziel, Auchenleck; Mr. Arthur Ross, Kilmalcolm; and Mr. John Loan, Coldstream.

Novelty Trial Awards.

In accordance with the conditions applicable to the trials of new Sweet Peas conducted by the Society at Helensburgh, the seedlings had been inspected twice by the judges during the period of growth, and they were staged in vases for the final adjudication which resulted in the following awards being made:—

Gold Medals.—To All Bright, cerise-scarlet, raised by Mr. C. C. Morse and Co., California; and Sheila, deep rose, from Mr. W. E. Sands, Lisburn, Northern Ireland.

Silver Medals.—To a salmon-pink seedling, raised by Mr. Robert Bolton and Son, Birdbrook; this variety was reserved for the Gold Medal by the National Sweet Pea Society; and a rose-cerise seedling, from Messrs. C. C. Morse and Co.

First Class Certificates.—To Loch Lomond, maroon, from Messrs. R. Bolton and Son; Purple Flame, from Messrs. C. C. Morse and Co.; Majestic, Purple, from Mr. W. E. Sands; a rose on cream ground seedling, from Mr. J. Stevenson, Wimborne; and Scintillant, rose, from Mr. J. Stevenson.

Certificates of Merit.—To Craigwell, salmon-pink, from Mr. F. C. Woodcock, Walmer; Admiration, rosy lavender, from Mr. F. C. Woodcock; Beatall, cerise-pink, from Messrs. R. Bolton and Son; an orange-scarlet seedling, from Messrs. R. Bolton and Son; Excelsior, blue, from Messrs. Dobbie and Co., Edinburgh; Lustre, carmine, and Purity, white, from Mr. J. Stevenson; a rose-cerise seedling, a deep pink seedling, a lavender seedling, a blue seedling, and a soft cerise seedling, all fine varieties, raised by Messrs. C. C. Morse and Co.; Leviathan, maroon, from Messrs. Stark and Son, Fakenham; and Mrs. Cinders, orange-scarlet, from Messrs. Ireland and Hitchcock, Marks Tey.

Trade Awards.

Gold Medals.—To Messrs. Dobbie and Co. (2) for Sweet Peas and Roses; Messrs. Austin and McAslan, for Roses; Mr. R. Lawrie, Carnwath, for Begonias; Messrs. Campbell and Son, for Carnations; the Scottish Wholesale Co-operative Society, for Roses; and to Messrs. R. K. Gemmell and Co., for Sweet Peas and Roses.

Silver Medals.—To Messrs. Bannatyne and Jackson, for Roses and hardy flowers; and to Messrs. Leighton, for hardy flowers.

ROYAL HORTICULTURAL.

August 13.—Notwithstanding that it was held in the height of the holiday season there was a goodly exhibition at the Society's new hall on the occasion of the meeting of August 13. Gladioli were prominent and provided the bulk of the display, but Phloxes were well shown and seasonal border flowers were of brilliant colouring. An outstanding exhibit was arranged by Mr. Amos Perry—the lecturer for the afternoon—who contributed a wonderfully fine collection of Nymphaeas, Sarracenias, Ferns and other water-loving and bog plants.

Orchid Committee.

Present: Mr. Charles H. Curtis (in the chair), Mr. Gurney Wilson (Hon. Sec.), Mr. Fred. K. Sander, Mr. Arthur Dye and Mr. T. Armstrong.

Only four plants were submitted for awards and the only award recommended by this small committee was a Cultural Commendation to F. Mercer, Esq., for Aerides Fieldingii.

Groups.

Only one group of Orchids was forthcoming on this occasion and it was from Messrs. Charlesworth and Co. Outstanding subjects were Cattleya Warscewiczii with half-a-dozen flowers, C. Hardyana var. alba, with nine lovely blooms, C. Dupreana, Brasso-Cattleya Ilene, the light yellow Laelio-Cattleya Daffrosa, Cypripedium Curtisii and its pale variety Sanderae, the old C. Charlesworthii, Odontonia Etna, a bright set of hybrid Odontoglossums, the quaint, long-spiked, pellucid-green-flowered Eria stellata, Cirrhopetalum guttatum, Maxillaria longisepala, and the graceful Oncidioda Charlesworthii.

Messrs. Black and Flory submitted a few seedling Miltonias obtained by crossing M. Bleuana var. Reine Elizabeth with M. Beau Brummel; these were very pretty. Messrs. Cowan and Co., and Messrs. J. and A. McBean showed individual plants, and a good example of Aerides Fieldingii, carrying a long and particularly fine spike was shown by F. Mercer, Esq. (gr. Mr. Banks), Clovelly, Stenning. (Cultural Commendation.)

Floral Committee.

Present: Section A.—Mr. Henry B. May (in the chair, Mr. Arthur Turner, Mr. B. R. Long, Mr. A. E. Vasey, Mr. James B. Riding, Mr. William Howe, Mr. D. B. Crane, Mr. Charles E. Pearson, Mrs. Helen Lindsay Smith, Mr. Courtney Page, Mr. W. B. Gingell, and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. Charles T. Musgrave (in the chair), Mr. James Hudson, Mr. G. Yeld, Mr. Reginald Cory, Mr. E. A. Bowles, Mr. G. Reuthe, Mr. L. R. Russell Mr. W. Irving, Mr. Amos Perry, Lady Beatrix Stanley, Hon. Henry McLaren, Mr. Clarence Elliott, Mr. Gerald W. E. Loder, Mr. T. W. Taylor, Mr. T. Hay, Mr. W. G. Baker and Mr. N. K. Gould, Secretary.

Awards of Merit.

Fuchsia corymbiflora (*seedling*).—The award to this handsome Fuchsia is subject to its being named. It is similar to Fuchsia corymbiflora but bears longer, pendulous clusters of richer-coloured flowers. Shown by Mr. A. J. Cobb, University College Gardens, Shinfield, Reading.

Gentiana prolata.—A very pretty species from Bhutan. It makes a dwarf, rounded plant. The relatively large flowers are of sky-blue colour with white tubes, and are solitary on stiffish stems about six inches long and set with tiny lanceolate leaves. Shown by Andrew Harley, Esq., Devonhall, Muckhart, Perthshire.

Pinguicola gypsicola.—A Mexican insectivorous plant, chiefly of botanical interest. It bears bright mauve flowers on erect little stalks. Shown by The Director, Royal Gardens, Kew.

Salvia patens var. Cambridge Blue.—A very delightful companion plant to the well known rich blue, Mexican, half-hardy perennial. The flowers are of real sky-blue colour. Shown by Mr. T. Hay, Hyde Park, London.

Streptocarpus Improved Aldenham Strain.—Many flowers of distinct and charming shades of colour were shown and they all evidenced first-rate cultivation. Shown by the Hon. Vicary Gibbs (gr. Mr. E. Beckett), Aldenham House, Elstree, Herts.

For Trial at Wisley.

Viola cornuta var. Lavender Gem.—The plants were of compact habit and bore plenty of medium-sized blue-lavender flowers.

Viola cornuta var. White Gem.—This is a white counterpart of the above and the flowers had pale yellow tubes. Both varieties were shown by Messrs. Watkins and Simpson, Ltd.

New Dahlias.

The Joint Dahlia Committee met for the first time this season and selected the following seedling Dahlias for Trial at Wisley :—

Mabel Crossling.—A showy Miniature-Paeony flowered variety of glowing scarlet colour. Shown by Mr. A. J. Cobb.

Ringdove.—A large Cactus Dahlia of the best exhibition type. The long, rolled florets are flushed with bright salmon-pink. This, and the the following, was shown by Messrs. J. Stredwick and Sons.

Winnie.—A large Cactus variety with broad pale yellow florets, heavily flushed with lilac.

Mrs. F. D. Durham.—A handsome large decorative variety of glowing pink colour.

Mrs. W. E. Phillips.—A large decorative Dahlia of substantial type and yellow colour.

Groups.

An exceedingly valuable and interesting group of aquatic and allied plants was set out in a most attractive manner by Mr. Amos Perry and deservedly received the Society's Gold Medal. It was one of the most comprehensive collections of its kind that we remember. There appeared to be everything possible and desirable, at this season, for the Water and the Bog Garden, even to the aquaria of the rare and fascinating little fishes of which Mr. Perry has so complete a collection. To the cultivator the finest part of this wonderful exhibit was the flowers of so many of the hardy Water Lilies, which were superb in their size and quality. The Nymphaeas included Virginale, an immense white flower; Marliacea, rose, of rich colour; Marliacea chromatella, of deeper yellow colouring than usual; Murillo, crimson; and Escarboucle, deep rich crimson. There was also an admirable collection of Sarracenias which included S. purpurea, S. intermedia and S. Mitchellii, with Darlingtonia californica. A great many of the more ornamental Reeds and Rushes, with Butomus umbellatus in full flower, Droseras and Loosestripes, were included.

Just inside the hall Messrs. J. R. Pearson and Sons had a very interesting group of desirable Marigolds of all the best types and varieties and they also showed, in their Liveland's Strain, a good type of dwarf Dahlia. Messrs. J. Cheal and Sons had a prettily-arranged table of early Dahlias of many types and Mrs. G. M. D. Dodd, Broom Lodge, Bracknell, showed a selection of Dahlia Seedlings, chiefly of the Collerette type. Mr. H. Hemsley again showed a good selection of his improved Sidalceas and Mr. John Golding had a well-arranged collection of Scabiosa caucasica. Mr. W. Yandall had many pans of Viola flowers in distinct varieties of considerable garden value.

A large collection of Pentstemons of greatly improved varieties was staged by the Hon. Vicary Gibbs (gr. Mr. E. Beckett), Aldenham House, Elstree. These bore erect branches of large, well-marked flowers of pleasing colours. The many varieties included Lovely, H. J. Elwes, Rosealba, Lord Hunsdon, Aldenham Gem, Masterpiece and Scarlet Lady.

Miscellaneous border flowers were shown in considerable quantity and of good quality. Messrs. G. and A. Clark included secondary spikes of Delphiniums and Heleniums; Messrs. B. Ladhams, Ltd., had many fine spikes of perennial Lobelias, Astilbes, Phloxes and spikes of Yucca filamentosa; the Misses Hopkins had many useful border flowers; Messrs. L. R. Russell, Ltd., showed Phloxes and also a collection of Fuchsias in small pots; Mr. A. Miles included Gaillardias and Coreopsis; Mr. S. F. Goodliffe grouped Phlox and Liatris, spicata with other flowers; Mr. Geo. E. P. Wood and Messrs. E. J. Redgrove and Son had varied collections of interesting flowers.

Another large and well-arranged collection of herbaceous Phloxes was contributed by Mr. H. J. Jones. As on the previous occasion he had exceedingly good trusses. The chief varieties were Mrs. H. J. Jones, Maiden's Blush. W. M. Jacobs, Le Madhi, Attraction, Thor, Europe and Evangeline.

A collection of half hardy shrubs from Messrs Robert Veitch and Son included floriferous sprays of Eucryphia pinnatifolia, Escallonia Iveyi, Desfontainea spinosa and Erythrina Crista-galli. They also showed branches of Hippophae rhamnoides with clusters of yellow fruits, and in Erica cinerea var. Francia, a graceful dwarf Heather. Messrs. Hollamby's Nurseries grouped many Clematis of good varieties with well-fruited little bushes of Pyracantha coccinea (Crataegus Pyracantha).

Their customary collections of well-grown Carnations were staged by Messrs. C. Engelmann, Ltd., and by Messrs. Allwood Bros. while good Roses were shown by Messrs. B, R. Cant and Sons and Mr. J. H. Pemberton. Messrs. M. Prichard and Sons had a few hardy Nymphaeas with an excellent group of border flowers which included Kniphofias (Tritomas) of good varieties, Calla palustris and Agapanthus umbellatus albus. Messrs. Stark and Son associated flowers of a desirable strain of Iceland Poppy and also Dazzler, a richly-coloured double-scarlet Shirley Poppy, with Sidalceas and other border flowers.

In view of the Gladiolus show there were many good spikes on view. Messrs. Kelway and Son showed such large-flowered varieties as Rose Precocé, Madge Parkinson, Margie Kelly and Dorcas, and also had a good selection of Primulinus hybrids. Messrs. Wakely Bros. and Co., staged many large-flowered sorts of good quality. Mr. H. Prins has a large collection and also showed many richly-coloured spathes of Richardia Elliottiana. Mr. George G. Whitelegg included Red Emperor, Brilliant and Electra in his collection. At the end of the hall, Messrs. W. J. Unwin, Ltd., had a delightfully-arranged group of Gladioli. The chief large-flowered varieties were Yvonne, Taro, Rose Precocé, Dr. F. E. Bennett, Red Emperor and Pride of Haarlem. Messrs. D. Stewart and Son showed good spikes of both types of Gladioli, while Messrs. R. H. Bath, Ltd, used the graceful Primulinus hybrids to good effect.

The Foremarke Cup competition was responsible for several exceedingly good exhibits. The Cup was won by W. E. Phillip, Esq., Wood Green, whose excellent spikes included Golden Dream, Heliosa, Ffitzer's Triumph, Red Emperor, Bertie Snow, Queen Mary and Roi Alexander. Messrs. H. Langridge and Co. were second and Mr. H. Prins was third.

Fruit and Vegetable Committee.

Present : Mr. E. A. Bunyard (in the chair). Mr. H. S. Rivers, Mr. G. Kelf, Mr. W. H. Divers, Mr. H. V. Taylor, Mr. J. Basham, Mr. J. C. Allgrove, Mr. E. A. Laxton, Mr. George Woodward, Mr. E. Beckett, Mr. W. F. Giles, Mr. Joseph Cheal, Mr. A. Poupart, Mr. R. H. Hall, Mr. T. Pateman, Mr. G. F. Tinley, Mr. A. Bullock, Mr. W. Poupart, Mr. F. Jordan and Mr. H. Markham.

Mr. Kettle exhibited Raspberries and Mr. J. C. Allgrove sent a few varieties of Gooseberries for the consideration of the Committee, otherwise there were no exhibits, nevertheless the Committee had a long sitting, discussing certain matters in private.

ROYAL HORTICULTURAL OF IRELAND.

The Summer Show of this Society, which was held in the Sandymount Hall of the Royal Dublin Society on August 7, 8 and 9, was in every particular a pronounced success. Entries in all sections were a record, and the quality of the exhibits little short of marvellous, having regard to the abnormally dry summer and the terrific rainstorm which succeeded it. A delegation from the Royal Horticultural Society of England, consisting of the Hon. H. D. MacLaren, Mr. Mark Fenwick and Mr. Reginald Corry were present at the opening of the Show, and were eloquent in their praise of the excellence of the exhibits; they presented four Gold Medals for competition in the nurserymen's section and these were awarded to Messrs. Alex. Dickson and Sons, Messrs. S. McGredy and Son, the Donard Nursery Co. and Messrs. Sutton and Sons (Reading), the last for a magnificently-staged collection of vegetables consisting of nearly two hundred dishes.

Apart from the trade exhibits—amongst which were Messrs. Alex. Dickson and Sons' superb stand of Roses, comprising close on five thousand blooms; Messrs. Allwood Bros.' magnificent show of Carnations; Messrs. McGredy and Son's glorious display of Roses; the wonderful Phloxes staged by Mr. James Dugan, Carlow; the serried ranks and gigantic baskets of exquisite Roses put up by the Donard Nursery Co. and the brilliant collections of Gladioli and Sweet Peas staged by Sir J. W. Mackey, Ltd.; Messrs. Carter and Co.; Mr. George Watson: Messrs. Spiers, Athy, and others; and the lovely Rock Garden and Lily pool arranged with such realistic effect by Messrs. Wm. Drummond and Sons, Ltd.—the exhibits from private gardens were of outstanding excellence.

In the large groups of ornamental foliage and flowering plants occupying the floor space in the centre of the spacious hall, the Hon. A. E. Guinness (gr. Mr. Stevens), took premier honours with a splendid collection of richly coloured Coleus, Palms, and flowering plants in variety. In the groups of hardy ornamental and flowering shrubs it was highly satisfactory to note the splendid display put up by Mrs. Stephenson (gr. Mr. Buggle), Stillorgan Road, which was a close second to the superb lot arranged by the Donard Nursery Co.

In the cut flower section, the display was pronounced equal to any seen at any of the cross-channel shows. Sweet Peas constituted the *piece de resistance* in this department; the glorious groups staged by Mrs. Alfred E. West (gr. Mr. C. E. Coster), Lord Ardee (gr. Mr. W. Barrett), Mr. Faulkner (gr. to the late Lord Rathdonnell); and Sir J. W. Mackey, Ltd., being quite "too beautiful for words." Gladioli were rarely more largely, and certainly never more attractively shown, and here, as in Sweet Peas, Mr. Chas. E. Coster was invincible in the Cup and principal classes. Annuals formed a charming feature, the chief honours being deservedly won by Wisdom Hely, Esq. (gr. Mr. W. H. Orr); Dahlias, Begonias, Pentstemons, Phloxes, Antirrhinums, Carnations, etc., were all magnificently shown, and the competition of the keenest order.

There was a large display of fruits, the Grapes, Melons, Peaches, Nectarines, etc., calling forth unlimited praise, while hardy fruits were to be seen in their thousands, and all of the very highest quality despite a somewhat trying season.

In the vegetable section, Mr. Stevens, as usual, showed how the produce should be grown; his collections both in the championship and the twelve classes, being models of perfect cultivation and staging.

Medals—gold, silver, silver-gilt and bronze, R.H.S., R.H.S.I., Banksian, Floral and journalistic—were plentiful "as leaves in Vallambrosa," yet in no case were they undeservedly awarded. The only shadow in this truly enjoyable reunion, was that caused by the absence, through illness, of the courteous and beloved Secretary, Mr. E. Knowldin.

ANSWERS TO CORRESPONDENTS.

Apple Foliage Curling.—*C. B. F.* The foliage of the Apple Cox's Orange Pippin does not show any sign of having been attacked by either insects or fungi. As you stated that the trees are not suffering from lack of water, the curling is probably due to the check which the trees received recently from low night temperatures following high day temperatures.

Begonias and Gloxinias Unhealthy. — *N. M. A.* The Begonia leaves are attacked by thrips and mite. Dipping the plants in a nicotine-soap wash will eliminate both these pests. As the eggs are unharmed by the wash, the operation should be repeated two or three times at intervals of ten days. The Gloxinia foliage is affected by a bacterial spot disease, the outcome of growing the plants in a humid atmosphere. Reduce the amount of water vapour in the house by lessening the amount of moisture used in damping down and overhead syringing.

Melons.—*A. B.* When Melons are grown in pots and plunged close together, or planted out one foot apart, they should always be grown as single cordons, as space for laterals is extremely limited, consequently very close pinching is necessary. Each lateral may be pinched close back as soon as seen and succeeding spray growths removed; in this way the true cordon form is retained. All laterals showing fruit may be pinched at one leaf beyond the fruit, while those from which superfluous fruits have been removed should be kept pinched to the first joint from the main stem. If two or more cordons are desired from one plant, allow more space, but the general manipulation and other details of culture are always the same, care always being taken to preserve the main leaves. These remarks apply to plants from which very early and very late fruits are the leading object, but they are altogether out of place for Melons grown on the extension principle.

Names of Plants.—*W. D.* 1, Campanula carpatica; 2, C. Poscharskyana; 3, C. cochlearifolia; 4, Sedum sp. (send in flower); 5, Epilobium sp. (send in flower).—*Constant Reader.* Hieracium aurantiacum.—*R. E. F.* 1, Isatis tinctoria; 2, Dictamnus albus; 3, Hemerocallis fulva.—*S. J. W.* Campanula lactiflora.—*G.* 1, Chrysanthemum maximum; 2, Centaurea macrocephala; 3, probably a form of Allium oleraceum; 4, missing; 5, Asperula odorata; 6, Lychnis chalcedonica alba; 7, Veratrum nigrum; 8, Kalmia latifolia var. myrtifolia; 9, Hypericum calycinum; 10, missing; 11, Trachelospermum jasminoides; 12, Lupinus arboreus. *A. A.* Potentilla fruticosa.—*A. W. R., Spalding.* Castanea sativa (Sweet Chestnut).—*J. W. N.* 1, Aglaonema commutatum; 2, Sansevieria canaliculata; 3, Calathea Lietzii; 4, Maranta bicolor var. Kerchoveana; 5, Strobilanthes Dyerianus; 6, Nephthytis picturata; 7, Aglaonema Haenhii; 8, Dieffenbachia imperialis; 9, Hoffmannia Ghiesbreghtii var. variegata; 10, H. Ghiesbreghtii; 11, Alocasia macrorhiza variegata; 12, Rhoeo discolor; 13, Panax Balfourii var. variegata; 14, Acalypha Godseffiana; 15, A. Hamiltoniana; 16, Isoloma hirsuta; 17, Nandina domestica; 18, Sanchezia nobilis; 19, Heliconia Seemannii; 20, Heliconia Bihai; 21, Dieffenbachia Carderi; 22, Aeschynanthus Lobbianus; 23, Coccoloba grandifolia.

Radium Sand.—*E. W. Pope.* The material sent consisted mainly of red and white silicious sand, the red form coloured with iron. It contained small pebbles of white quartz and flint, with some particles of mica, and some small pieces of glass or spar. None of the above materials would supply any plant food, except silica, useful in strengthening the stems of cereals, grasses, sedges, etc. It is reputed to contain radium, a recently discovered chemical element capable of giving off heat over a very long time, and so stimulating the growth of plants, independently of sun-heat. Radium is very scarce everywhere, and whether or not there is sufficient in this to make an appreciable difference to the growth of plants is a matter for experiment. You could try some of it in the soil for potting some plants, and potting some others in the same compost, without the sand, to see whether or not there is any difference in growth. It could also be used for vegetables in the garden, with a control plot alongside to see if there is difference in growth, earliness or maturity. The sand evidently occurs in this fine form naturally, and does not seem to have been ground, although it could have been crushed to break up the hardened pieces, because the small pebbles have not been broken, but have been water-worn in an ancient bed of the sea. If it shows no appreciable improvement in the growth of plants, it will not do them any harm.

Sweet Peas with Streak.—*J. C., J. G.,* and *W. C.* The Sweet Peas are suffering from "streak," which is due to the bacillus, B. lathyri. The disease is encouraged by an excess of nitrogenous manures in the soil. The infected plants may be induced to grow away from the attack by watering them with a solution of sulphate of potash (one ounce in five gallons of water), using about one pint to each plant and continuing the treatment at weekly intervals until clean growth is seen. Remember that the disease may be spread from an infected to a healthy plant by means of a pruning knife.

Tadpoles in Ornamental Water.—*J. F. S.* The tadpoles got into the Water Lily pool by frogs laying their eggs there early in the spring. They lie up in hiding during the winter, and when breeding time arrives they go hunting for pools of water. In a short time after the eggs are laid, you will find one or more balls of eggs in a floating mass of slime. The eggs can be seen like small, black eyes embedded in the slime—hundreds of them. By means of a piece of sacking you can lift out the whole mass and carry it away to be deposited in some dry place exposed to the sun, and the whole will dry up, thus preventing the presence of tadpoles in the water. In the meantime, by the aid of an improvised butterfly net, of any thin fabric, tied to a circular wire, with a handle you can soon fish out all the tadpoles in the water. Much of the green, slimy vegetation in the pool can be taken out by the same device. Cement-lined pools should be emptied and scrubbed out every year in March or April.

Tomatos Failing to Colour. — *Constant Reader.*—The failure of your Tomatos to ripen and colour is, as you suggest, due to lack of potash in the soil. This condition is best remedied by applying a light dressing of nitrate of potash, which should be watered in well.

Thyme and Campanula Failing.—*J. M. C.* The plants of Thymus lanuginosus and Campanula carpatica appear crippled and burnt up, which may be due to the conditions under which they are growing. The general appearance of the plants is unhealthy, but there is no sign of disease organisms on the plants.

Thuya occidentalis and Live Stock.—*J. D.* The American White Cedar or Arbor-Vitae (Thuya occidentalis), along with other species of Thuya, such as T. Lobbii, T. plicata and T. gigantea has frequently been held responsible for the poisoning of live stock. Unfortunately, little is known concerning the actual poisonous properties of these plants. Many cases of fatal poisoning from Thuya occidentalis are on record, but on the other hand stock have also been observed to eat the foliage without noticeable ill-effects. It is thought by those in a position to judge that the poisonous principle may vary in amount in different localities and at different seasons. This is known to be the case with certain other poisonous plants. Probably also a fairly large amount must be consumed for the effect to prove fatal, and stock in the habit of nibbling small quantities frequently are less liable to be affected than those that that eat the plant as a result of access to it for the first time. The fact that Thuya occidentalis is sometimes used medicinally points to its not being violently toxic. A decoction prepared from the leaves is used for intermittent fevers and coughs, and mixed with lard as an ointment in cases of rheumatism; while a volatile oil extracted from the shoots and leaves is sometimes used as a vermifuge. In considering plants for hedge-planting on farms it is advisable to bear in mind the suspicion that has come to be attached to Arbor Vitae where live stock are concerned, especially as other safe hedge plants can generally be substituted.

Vine foliage with Mildew.—*J. W.* The vine foliage is attacked by mildew and should be dusted in the early morning with green sulphur. The water supply to the plants is inadequate, as some of the leaves show symptoms of having suffered from lack of water. There is some "scorch" and the variety may be one that requires shading during bright, sunny weather.

SUPPLEMENT PLATE.

Astilbe simplicifolia var. rosea.

AVERAGE MEAN TEMPERATURE for the ensuing week deduced from observations during the last fifty years at Greenwich, 60·2°.

ACTUAL TEMPERATURE—
The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, August 21, 10 a.m. (Greenwich time). Bar. 30·2. Temp. 62°. Weather, overcast.

The Drought. THE drought, as severe as sporadic, has resumed its sway in the south. Somewhere about the latitude of Scarborough in these islands is the dividing line between the regions of too little and quite enough recent rain. In the north, although they feared a drought, none came, and from Northumberland northward through the Scottish counties the pastures are still green and white—green with the pasture grasses, and white with Wild White Clover, the scent of which makes all the country air from Berwick to Aberdeen deliciously sweet. Coming south again down the western side of England, the full force of the drought is met on the light Herefordshire soils where pasture ground is burnt hard and keep for cattle already becoming scarce again. Back in Berkshire, although the gardens are still beautiful, the signs of drought are on every hand. Sun-loving plants, Zinnias, for instance, are repeating the brilliant sunshine by rainbow brilliance of flower. Roses also are enjoying the sun and responding to it by florescence and growth beyond the usual and beyond easy explanation. Certain other plants show unexpected reactions to the dry weather and sunshine; and the Brooms, for instance, both Cytisus aetnensis and Spartium junceum, were in flower a month ago and are only just going over. Strawberries, on the other hand, have never in all their lives looked so miserable. They fruited badly, and where neglected with respect to water have gone on looking worse ever since their few and somewhat acid fruits came to an untimely end. Why fruits should lack sweetness as a result of sun and drought is not readily explicable. Size they should lack, but not sugar. Of plants which have responded to drought by reducing their floral display, the most striking, perhaps, are the Immortelles—Helichrysum species. Instead of bursting out and bearing many of their papery flowers, each remains a miserable one-headed plant which needs must be cut down and well watered if it is to grow at all. The fruit-grower finds a heavy crop of troubles to diversify his pleasant lot. Last year he had heavy crops of Plums and wasps, and unless he fought the latter unceasingly the insects had the best of the fruits. This year when Plums are scarce—at least in some districts—wasps seem to have decided that there is nothing to live for, and have not bothered to get born. But with Apples fairly plentiful and water scarce, the birds—and those bad birds, the sparrows, to boot—have already started pecking and scooping out the flesh of these fruits. Another pest that makes trouble in the garden is the mole. Where the ground is dry it does not come, but so soon as a garden crop looking in perilous need of water gets a good drenching, the moles seem to congregate, and their underground passages, each a devastating earthquake to the roots of seedlings or young plants, increase and intersect in all directions. Thanks, however, to calcium cyanide—a pinch here and there in the runs—this pest may be scotched. Of all the effects of drought combined with sunshine, that manifested in upturned heavy soil is, perhaps, the most wonderful and instructive. In this garden, where we write, is a pond in the making. The excavated clay—heavy slabs of blue Kimmeridge clay—has been spread three feet deep over a meadow. In ordinary years these slabs would have the durability of tombstones. Not so this year. So soon as they are thrown out of the barrow fissures appear in them, and over the blue colour steals a brownish tint as the ferrous sulphide is oxidised. The fissures join and intersect until a kick with the foot causes the erstwhile slab of greasy, iron-hard, unkindly clay to crumble into little chunks and fine powder. Over there where the slabs have had the winter frosts as well as summer sun and drought to teach them kindliness, they are now reduced to finest powder, and on that ground which consisted a year ago of unweathered clay there is to-day a crop—and quite a moderate crop—of Onions, growing with not many misses in the rows. Not in many years would it be possible to see in such dramatic manner the fertilising effect of frost and sun. Thus it is indeed brought home to the observer how much our gardens lose, at least in some directions, by open winters and overcast summers.

Our Supplement Plate.—Astilbe simplicifolia var. rosea is the plant depicted in the Supplement Plate presented with this issue. A. simplicifolia is a charming subject and one in which the late Mr. Reginald Farrer found great delight. He regarded it as "a gift of the gods from Japan, which turned up 'unbeknownst' one day in an imported mass of Schizocodon, and ere long revealed itself as the most lovely Astilbe imaginable, for any cool, moist and shady corner on the most select of rock-works." A. simplicifolia produces "airy, eight-inch plumes of white blossom," and its variety rosea is equally valuable and beautiful, for its flowers are of a soft rose-pink shade.

Horticultural Travellers.—Two well-known horticulturists are on their way to America, and each proposes to combine business with pleasure over a period of several months. They are Mr. A. McBean, of Messrs. J. and A. McBean, Orchid growers, of Cooksbridge, and Mr. C. Engelmann, of Saffron Walden, who specialises in Carnations, but is equally clever in the management of Roses, Orchids, and many other things.

Diamond Wedding of Mr. and Mrs. Luke Dann.—Mr. and Mrs. Luke Dann, Chatsworth Place, Harrogate, celebrated their diamond wedding on August 14. Mr. Dann is eighty-five and his wife is one year his junior. Mr. Dann was gardener in the employ of the Harrogate Corporation for about thirty years, and up to his retirement a few years ago. He recalls that the Crescent and Baths Gardens, when he entered the service of the Corporation, were over-grown orchards, and the Valley Gardens were then a big field.

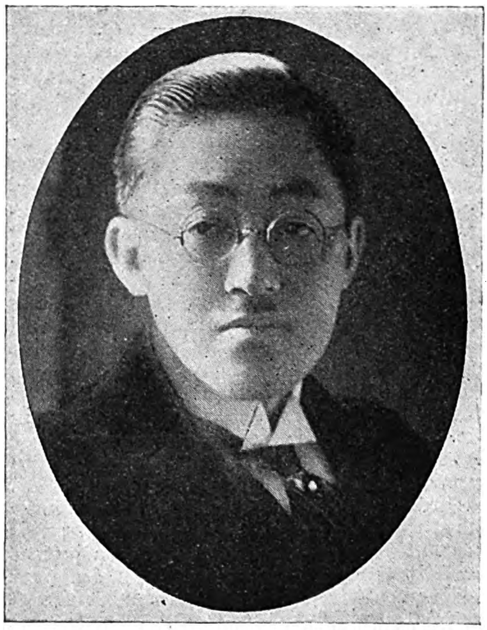
Glasgow Flower Show.—We learn that arrangements have been completed for the annual flower show promoted by the Corporation of Glasgow in conjunction with the Glasgow and West of Scotland Horticultural Society, which takes place in the Kelvin Hall, on September 3, 4 and 5. The show, which will be opened by Lady Inverclyde, will occupy practically the whole of the City's vast exhibition hall, and it promises to be a great success. The schedule of prizes contains no fewer than 467 classes, and apart from Cups, Trophies and Medals, a sum of £1,200 will be given in awards. Sections include rock and water gardens, pot plants, cut flowers, including Roses, Sweet Peas, Carnations, Dahlias, Chrysanthemums, Gladioli, Pansies and Violets, etc.; vegetables, decorative classes, and special classes for allotment holders and honey and bees. The principal awards are given in the class for rock, or rock and water gardens, £85 being divided among the four leading exhibitors. Cards will be shown on the winning exhibits setting forth the number of points given by the judges for design, proportion and shape; the setting of the stones; colours chosen in planting; skill in regard to grass-laying, planting, etc., and quality, suitability and rarity of plants. For a group of miscellaneous stove and greenhouse plants, £85 is awarded in three prizes, the first prize winner also securing the Corporation of Glasgow Challenge Cup, valued at £50. For eight bunches of Grapes, not more than two bunches of any one variety, the first prize is £9, along with the Thomson Challenge Trophy; and the Sir John Reid Challenge Cup, along with £4, is awarded to the winner in the class for four bunches of Grapes. The Lord Maclay Challenge Cup will be presented to the winner in the class for the best collection of vegetables containing thirteen varieties, the money awards being £8 for the first prize, £6 for the second, £4 for the third, and £2 for the fourth.

The Original British Larches.—Visitors who pay a visit to the famous woods of Birnam, immortalised in Shakespeare's *Macbeth*, situated near Dunkeld, Perthshire, should visit Dunkeld Cathedral, in the grounds of which they will find, at the north-west corner of the building, two magnificent Larches. These are considered to be the first examples of this tree to be introduced to Britain, and were brought from Switzerland in 1737. They were first planted in flower pots, but now they are magnificent specimens, tall and wide of girth. Expert woodmen declare the trees are still in perfect vigour.

Loch Ericht Tree Clearances.—An object lesson in what forestry is capable of doing for unemployment is furnished by the Loch Ericht tree clearance, which has given work to many men for months past. Planted some sixty years ago, by the late Sir John Ramsden, and situated 1,000 feet above sea-level, the forest throve splendidly, but the terrific gales of January, 1927, played havoc, and some 20,000 trees were blown down. The removal of these has given employment to many men. The work was arduous, many Spruce trees measuring ten to twelve feet in circumference. The Larches also were fine specimens, their height averaging from forty to sixty feet. Hauled to the lochside, the trees were rafted and towed down to the sawmills, where they were turned to commercial use. Now that this work is practically finished, another new job is in store for the men. It has been determined to still further thin the forest by cutting down 25,000 trees, which should provide another two years' work. The forest is one of the best in Inverness-shire, and even after these thousands of trees have been removed it will still appear to the onlooker as practically untouched, although it has provided four years' employment for a large body of men. The potentialities of the forests in northern Scotland in providing employment are obvious.

Dahlias in the London Parks and Gardens.—That the public parks and gardens of London have done much towards the achievement of the popularity enjoyed by the Dahlia at the present day cannot be gainsaid, for each year, at this season, Dahlias play a very prominent part in their adornment. For instance, in the Embankment Gardens the displays provided by Dahlias alone are magnificent, especially when it is considered that every Dahlia plant grown there is raised in the diminutive propagating quarters attached to the gardens, the Dahlias being started, and the cuttings rooted, in frames over hot-beds. Bordering the long, winding shrub borders are floriferous plants of Barlow's Bedder, red, and Kaiserin Augusta Victoria, white, two very serviceable small-flowered Decorative sorts, while especially attractive is the broad ribbon border, near the bandstand and with a railway arch beneath, so that there is no great depth of soil. In this border King Albert, a large-flowered, plum-coloured Decorative sort, associated with the free-flowering Brentwood Yellow; Glory of Schiedam, a grand white Mignon variety, and numerous other sorts, combine to make a very striking and pleasing colour scheme. Several large circular beds are filled with Coltness Gem and Glory of Schiedam, while around the bandstand are bays of Barlow's Bedder and Kaiserin Augusta Victoria. In St. James's Park the Dahlias are one of the chief features, being confined chiefly to the borders around the entrance from Bird-cage Walk. Here are to be seen massive banks of many grand varieties, skilfully arranged and all flowering freely. Prestige, a Decorative variety with enormous blooms, biscuit-orange, darker in the centre, and very free-flowering, is one of the most effective, while other sorts which play prominent parts in this massed floral display are Radium, a glowing scarlet, Paeony-flowered variety; Queen Victoria, a white-flowered Decorative Dahlia; Orange Perfection, a specially fine, large-flowered Decorative sort; and Bishop of Llandaff, a lovely Charm Dahlia with crimson-scarlet blooms and rich, dark foliage; it is backed by massive plants of the popular large-flowered Decorative variety Jersey Gem. Opposite the border containing the above is one in which Mignon varieties such as H. J. Jones, bright yellow; Princess Marie José, bright pink and free-flowering; and Glory of Schiedam, are skilfully arranged with such striking sorts as Ladybird, Pleasure, a Single variety, deep rose-red with a purple central zone; and Andreas Hofer, one of the few really decorative Cactus varieties for general purposes, with salmon-pink petals shading to cream at the base. The formal beds in front of Buckingham Palace are now ablaze with masses of the invaluable Coltness Gem, while in Hyde Park the annual display of Dahlias in the long border near the entrance to Kensington Gardens is again attracting many hundreds of visitors who seldom have such an opportunity of inspecting so representative a collection. The border is edged with Mignon varieties, outstanding among which are Midget, Moonbeam, Powerscourt Yellow, and H. J. Jones, in various shades of yellow; Harold, crimson; Glory of Schiedam, which would appear to be invaluable; Roy, velvety-crimson; Coltness Gem and Coltness Gem Scarlet, and Etna, crimson-scarlet. Among the taller sorts, which form a massive and glowing bank behind these, the most striking sorts at the present time—many have not yet attained their full beauty—are Thomas Hay, V.M.H., clear lilac; Blanche Rowland, orange-scarlet; Hyde Park Beauty, glowing rose; King Tut, dark purplish-crimson; Delightful, bronzy-yellow, white-tipped; Delice, rich pink; Mrs. Wheeler Bennett, yellow; Mrs. Ethel Smith, pale primrose; Henry Carleé, white; and Grace Curling, white and rose-pink, all large-flowered Decorative sorts; together with Seafield, a lovely Star Dahlia; Clematis, rose-lavender, and one of the most beautiful of the large-flowered Single varieties; Tuskar, a striking Collerette; and Argos and Andreas Hofer. A really grand display and very educational.

Commander Prince Shimadzu, I.J.N., M.V.O.—Prince Shimadzu, well known to Orchid lovers in this country, is President of the Japanese Floral Society and the Japan Dahlia Society as well as a member of the Committee of the Imperial Orchid Society of Japan. He is also a member of the Royal Horticultural Society's Orchid Committee. His chief horticultural interest lies in the raising of hybrid Orchids, and he has made this his hobby in his home in Japan, where several plants have already been named by him. His keen interest in his hobby is shown in the following story relating to one of his latest hybrids. Some years ago he crossed Dendrobium nobile with D. Felicity—which is itself a hybrid between D. Rainbow and D. Wardianum—of which he was able to raise several hundred seedlings. These reached their flowering stage last spring, but before that long-looked-for period arrived he had to leave Japan to take up his new appointment in London as Naval Attaché to the Japanese Embassy. Being afraid that he would be denied the opportunity of seeing this hybrid flower for some years to come, he decided to take three plants on board ship with him, through the Indian Ocean. As the voyage progressed the buds expanded and eventually they opened successfully on February 5, 6 and 7, in the middle of the Indian Ocean. He accordingly named the hybrid Dendrobium Indoyo—the Japanese name for the Indian Ocean. He brought his plants to England and, having no suitable place in which to keep them during the cold weather experienced in this country after his arrival, he presented them to Sir Jeremiah Colman, Bt., Chairman of the R.H.S. Orchid Committee, in whose collection at Gatton Park they now are.



COMMANDER PRINCE SHIMADZU, I.J.N., M.V.O.

"Journal" of the South-eastern Agricultural College.—The *Journal* of the South-eastern Agricultural College (University of London), Wye, Kent, for 1929, edited by Dr. S. Graham Brade-Birks, has just been published. It consists of two hundred and twenty-three pages and is mainly devoted to the consideration of the scientific work which is being carried out at Wye, although the Editor, in his notes, expresses the regret—and in this we entirely agree with him—that pressure of space prevents the publication of much that would have been interesting. The contents are naturally very varied and deal with many branches of the application of science to problems of agriculture and horticulture. A detailed account is given of the work of the Department of Agriculture. It deals with a number of field trials and experiments carried out in 1927-8. These include Potato manurial trials; an enquiry regarding Hops as a manure for Potatos; Sugar Beet variety and manurial trials; manurial trials for Swedes, Thousand-headed Kale, Mangels and Oats; experiments with temporary leys; pasture manures; permanent grass seed mixtures, and a pig-feed trial. A special section deals with weather records and the effect of climate on crops, and a summary of the year's progress on the College Farms, with a map, is given. The work of combating diseases of plants is dealt with by Mycologists, Entomologists and Chemists. The Agricultural Economists contribute an interesting article entitled "Another Clay Farming Episode." Room has been also found for an article on the rôle of photography as an aid to the examination of cattle foods. Other contributions include soil profile, precision records on Wheat, the reductase test, and millepedes and centipedes in relation to horticulture and agriculture. The article on "A Simple Diagnosis of the Plant Lice of Ribes and Apple," by Prof. Theobald, with coloured illustrations of the pests; and the one on the Apple Capsid and the Common Green Capsid, will be found of particular value to gardeners and fruit growers. Residents in Kent and Surrey may obtain copies of this useful publication for 4s. 6d. (post free), but those not resident in these favoured counties must pay 8s. 6d. (post free). Applications for copies should be made to the Secretary, South-eastern Agricultural College, Wye, Kent.

Scottish Pansy and Viola Association.—Major R. S. Milne, the President, presided at the Annual Meeting of this Association recently held at Glasgow, when the following awards were made:—Certificates of Merit: to Violas Dr. R. M. Craig and Nessie Douglas, shown by Mr. John Douglas, Uphall; Viola James M. Whyte, raised by Mr. William Whyte, Neilston; Fancy Pansy John Gourlay, raised by Mr. Harry Robertson, Kelty, Fife; and Mignon Dahlias, Crimson Gem and Pink Gem, of the Coltness Gem type, shown by Mr. Alex. Cochrane, Fauldhouse. A First Class Certificate was awarded to a seedling Chrysanthemum named Robert McAlpine, raised by Mr. Alexander McAlpine, Tollcross, Glasgow; the colour may be described as brick-red, and is quite distinct. At the business meeting Mayor Milne was re-elected President, and Mr. W. Dobbie, Schoolhouse, Renfrew, Hon. Secretary and Treasurer.

Horticultural Exhibition at Verviers.—A horticultural exhibiton is to be held at Verviers, near Spa, in Belgium, on the first three days in September. It will take the form of a celebration of the seventy-fifth anniversary of the foundation of the Verviers Royal Agricultural and Botanic Society, founded in 1854, and will be held in conjunction with the exhibition of the Belgian National Dahlia Society, and with that of the local allotment society. Verviers is a finely-built town of 100,000 inhabitants, and the exhibition is likely to attract a goodly number of foreign, as well as Belgian, visitors.

Weather in the Arnold Arboretum.—It is not in the British Isles alone that drought has affected gardens, for the *Bulletin* of the Arnold Arboretum dated July 26 conveys the information that "the scarcity of rain is affecting vegetation generally; the foliage on some of the shrubs is wilting, the trees, however, show little or no effects, but copious rains are badly needed." Of peculiar interest is the note concerning Heather—now so popular with us. The *Bulletin* states that: "Heather or Ling (Calluna vulgaris) in its various forms is blossoming in the Shrub Garden and elsewhere. Among low-growing, ground-covering evergreens none is more beautiful than this plant so dear to the heart of every Scotchman. There are a great many forms, distinguished by their habit of growth, and colour of blossoms, but one and all are equally lovely. The erect, leafy shoots bear in abundance axillary flowers which vary in colour from pure white and pink to crimson-purple. Heather is a sun-loving plant, but in these latitudes, unless favoured by good snow-falls it, like all low-growing evergreen ground-covers, needs protection from the latter half of January until April. Boughs with salt, hay or coarse herbage sprinkled over make a light and efficient protection. Heather is an acid-soil plant which does not transplant any too well from open ground and should, therefore, be grown for the purpose in pots. It is easily propagated by cuttings taken from August to mid-September and inserted in sand under glass. If allowed to grow naturally it becomes straggling and hummocky and is apt to die in patches; the same obtains when growing in the shade. To avoid this the Arboretum practice is to shear it each spring, thereby keeping it low and mat-like. In the British Isles, particularly in the northern part, in Scandinavia and elsewhere the Heather covers enormous areas of moorland and mountainside and in August presents one of the floral spectacles of northern regions. Although the plant covers vast areas in Europe and extends far into northern latitudes, Heather, unlike many other boreal types is not known to grow on this continent. About the middle of last century it was reported from Nantucket and later from several other isolated places in New England. Close investigation, however, has shown that in each instance there is every reason to believe it had been introduced. In fact, to-day, authorities have no hesitation in saying that so far as the discoveries in New England are concerned one and all are simply escapes from cultivation."

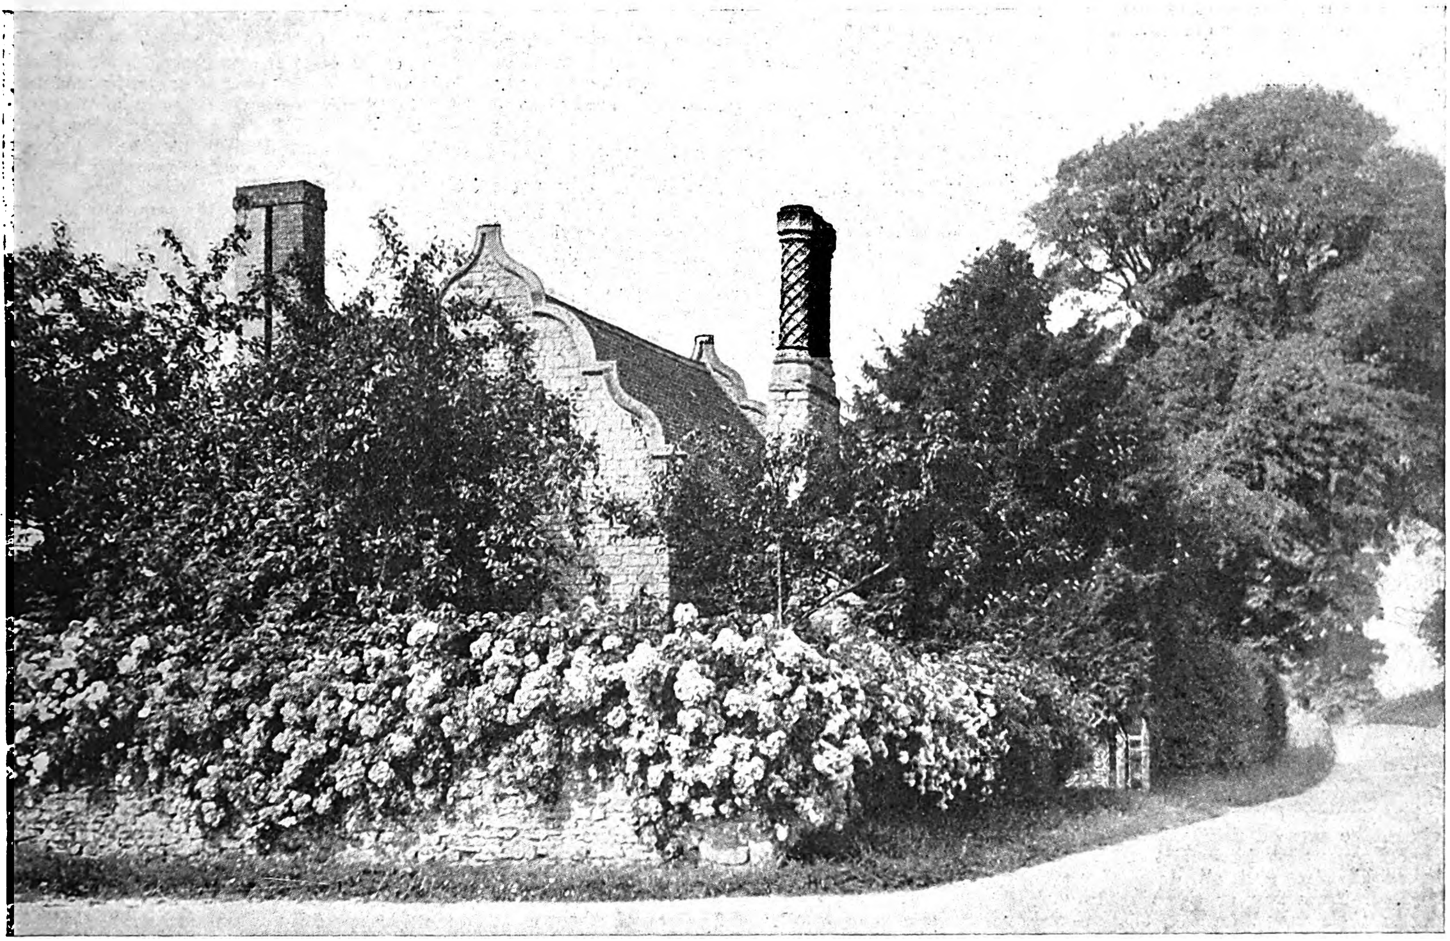


FIG. 72.—ROSES AT WARREN COTTAGE, LONGWORTH.

Roses at Warren Cottage, Longworth.—The Berkshire village of Longworth, in the Upper Thames Valley, is not much known, except for the Oxford Roses which are grown there by Mr. George Prince. The illustration (Fig. 72) shows Mr. R. Painton's home at the entrance to the village from the west. The soil is very sandy and light, but Roses thrive in it, doubtless on account of the moist sub-soil. Roses of the rambler type normally make growths of ten to fifteen feet and more, but only the best of these are annually pulled over the wall and tied in for the following season's display. The Roses on the wall are White Dorothy, Crimson Rambler, Dorothy Perkins, American Pillar and Hiawatha.

Appointments for the Ensuing Week.—MONDAY, AUGUST 26: Harrogate and District Horticultural Association's meeting. TUESDAY, AUGUST 27: Royal Horticultural Society's Committees meet; Royal West Renfrewshire Horticultural Society's meeting. WEDNESDAY, AUGUST 28: Southport Flower Show (three days); British Gladiolus Society's Exhibition (three days); *Daily News* Sweet Pea Show (three days); Newcastle and District Horticultural Society's meeting. THURSDAY, AUGUST 29: Royal Oxfordshire Horticultural Society's Exhibition; Sandy Floral and Horticultural Society's Exhibition; Dundee Horticultural Society's Show (three days); Leeds Paxton Society's visit to Southport Show. FRIDAY, AUGUST 30: Dunfermline Horticultural Society's Annual Exhibition (two days); SATURDAY, AUGUST 31: Falkirk Horticultural Society's Exhibition; Leeds Paxton Society's lecture.

"Gardeners' Chronicle" Seventy-five Years Ago.—*Aphis rumicis.*—It is singular that a species of plant louse, which is generated on the common Dock, should this year have infested Turnip crops in Yorkshire. I received the following communication from a gentleman residing near Richmond in Yorkshire:—"I send you specimens of the insect that has committed so much injury to the late-sown Turnips this year. These Turnips that were put in previous to May 24 have escaped. All my Turnips had farmyard manure applied, as well as 2 cwt. of guano. One part had bones instead of guano, which was much worse than the guano. The insects are invariably under the leaf. I have not, or rather, I did not, find any to-day at the root. There are now few left. I had some difficulty to find a good sample for you, but I fortunately met with some winged specimens. I had nine acres of the Hybrid Turnips destroyed last year." In a former letter to the Secretary of the Royal Agricultural Society, the same gentleman stated that "hundreds of acres are almost destroyed by this fly in the North Riding of Yorkshire and Durham"; and he added, "I have five acres quite destroyed and several more acres are more or less injured." Mr. F. Walker says that A. rumicis is hatched on the Dock, and then migrates to the Bean, Pea, Thistle, Chenopodium, Laburnum, Broom and Furze, but it is a new plague, I believe, in the Turnip field, as the only species hitherto known to injure the Turnip crops were Aphis Rapae, A. dubia, A. Brassicae, and A. Floris-Rapae. I believe A. rumicis was very abundant last year in the north of England. About the beginning of this month there were myriads of this species in the neighbourhood of London, and on the evening of the 1st, they were seen in prodigous numbers near Highgate, and soon covered the plants in the gardens, causing considerable mischief to the Dahlia buds. They died, however, in two or three days, after some very heavy showers. There is still a great deal to be learnt about these remarkable insects, for species which at one time seem to be attached to one plant suddenly affect others, and this may be the cause, in some instances, of their sudden death; as the sap of the Dahlia, for instance, may poison a species which was bred on the Dock, whilst the Turnip may be wholesome food for it. Electricity also appears greatly to influence the appearance and disappearance of the aphides. *John Curtis, Gard. Chron., August 26, 1854.*

The Week's Work.

THE ORCHID HOUSES.

By W. GILDEN, Orchid Grower to Dr. F. CRAVEN MOORE, Manchester.

Brassias.—Specimens of the distinct and sweetly-scented Brassia Lawrenceiana and its varieties are now producing their flower spikes and require plenty of light to assist in completing their new growths, although the foliage is quickly injured if strong direct sunshine is allowed to reach it during the hottest part of the day. The plants should be supplied with ample moisture at the roots each time the compost appears dry, until the new bulbs are matured, when a smaller quantity will suffice to keep the plant in health, although long periods of drought are not advisable at any time. If the plants are not in robust health, the flower spike should be removed so soon as the blooms expand. The more robust growers such as B. verrucosa and B. brachiata are growing freely along with the Cattleyas, and will require generous treatment, and moist surroundings to keep them growing sturdy; where the roots are well established in the compost, ample supplies of water will be needed each time they appear dry. As the growths advance, more light and air should be allowed to reach the plants. Scale insects should be sought for and destroyed when detected.

Miltonias.—Specimens of this free-flowering group of decorative Orchids which produced a brilliant display of flowers earlier in the season, have now commenced to grow again, after a short rest. The young growths should be examined frequently as the centre leaves often adhere to each other and require some help to get free. A smooth instrument, similar to the handle of a budding knife, may be used, for if these leaves are not separated in good time deformed growths will occur. Small thrips often infest the young leads and the axils of the leaves, and quickly disfigure the foliage if allowed to remain. Should any be found the leaves should be dipped in an approved insecticide, tilting the plants afterwards to allow the moisture to drain away. Any plants that require repotting may safely be dealt with when the growths are a few inches high and just as fresh roots are pushing from the base. Over-potting should be avoided as the fine roots do not easily penetrate a large mass of compost. Well-drained pots or pans should be used, while two parts of Osmunda fibre, one part Sphagnum moss, with a few broken Oak or Beech leaves, may be used as a rooting medium, and should be pressed firmly about the roots. Any specimens that have lost their centres should be divided and all decayed portions removed, retaining two or three bulbs behind each lead; these may then be potted separately or re-made into large specimens, as desired. Smaller plants that require more room may be potted on without greatly disturbing them, but all sour compost should be removed. Water should be afforded very sparingly until the roots are working freely in the new compost, when a larger quantity will be needed. The plants thrive well during the autumn and winter months in the intermediate house.

HARDY FRUIT GARDEN.

By HENRY H. COOK, Chief Assistant Lecturer, Reading University Horticultural College.

Strawberries.—The general planting should be completed without delay, so that the plants may become firmly established before the winter. It has been proved by Mr. Staniland, Long Ashton Research Station, that root activity practically ceases by the end of September, and does not recommence, to any appreciable extent, before March or April. Recently planted Strawberries should be well supplied with moisture at the roots during dry periods, and the early removal of all runners is desirable to divert the energy of the plants in the proper direction. The old plantation should receive an occasional hoeing to form a mulch of loose soil and to kill annual weeds. There should be no deep cultivation of the soil, such as digging, but the free use of the cultivator and the drawing of the soil up towards the base of the plants will greatly benefit the new roots which are now being emitted from the collar of the plants.

Raspberries.—Owing to the very dry season the young canes have not attained the average height this year. This deficiency may be made good, to some extent, even now, if all the old fruiting canes are cut out, and only a sufficient number of the young ones retained, and loosely tied in to their supports, all superfluous canes being pulled out. Then give the plantation a thorough soaking of liquid manure made from the drainings from the cow byre. The variety Lloyd George, might justly be termed a perpetual-bearing variety, as plants that were grown and treated for summer fruiting are now showing large terminal trusses of fine fruits, so that the application of liquid manure to such plants would be of the greatest benefit. This variety is undoubtedly the best autumn-fruiting Raspberry we have. The berries are very large, bright red in colour, and of good flavour. The Hailshamberry is not so large a fruit as the former, but the flavour is better and it produces ripe fruits over a long period.

Loganberries.—These have now finished fruiting, and the old canes should be cut out without delay. The growths should be loosely but securely tied to their supports. If the fence is formed of wire netting, the young growths of the Loganberry should be laid in rather thinly, at about a foot apart, and tied securely so that they may ripen up their wood for next year's fruiting. Besides, any such work accomplished now will not only be of the utmost benefit to the plants, but will help considerably to forward the winter's operations.

Propagation.—The propagation of the Loganberry is quite simple; but to perpetuate the best qualities of the plants it must be increased vegetatively, *i.e.*, by root-cuttings, or by layering. The latter method is that which is generally practised, and this is the time when it is done. All that is necessary is to bend over and bury, three or four inches deep, the growing tips of the current season's canes. In common with all the Bramble family, these tips, when buried, will form a fleshy, bulb-like growth, emit roots in quantity, and eventually shoots. These layers are severed from the parent cane in November, and planted in nursery rows for a year or two before being set out in their permanent quarters.

FRUITS UNDER GLASS.

By F. JORDAN, Gardener to Colonel SPENDER CLAY, M.P., Ford Manor, Lingfield, Surrey.

Strawberries.—Plants from which the supply of runners for forcing is to be obtained should be put out the year previous, upon the best prepared ground in the garden, fully exposed to sun and light, and in no way connected with the plants intended to yield a supply of fruits. If well mulched and watered and relieved of all flower spikes so soon as these are detected, strong runners will be produced in abundance. Strong runners layered from maiden plants and not required for forcing should be ready for turning out this month; mulched and watered and kept free from runners, they will soon establish themselves. Newly-layered or potted plants should receive careful hand watering, and not too frequent overhead waterings, unless the water is warm and soft, as the young foliage burns and soon becomes hard and spotted. Some growers object to the use of stimulants, and if large pots are used, stimulants are not so urgently needed, but much depends on the quality of the compost. As a rule, pot plants should be moderately stimulated from the time the roots are abundant until the foliage shows signs of maturity, when clear water will suffice all through the dormant period. Every effort should be made to grow sturdy plants as varieties have degenerated so much, and the weather has been more favourable to the spread of mildew than the production of strong healthy growths. Constant change of ground and the introduction of fresh, healthy stock, and spraying against green-fly are the best remedies for degeneration, especially with those varieties which fall away more rapidly than others.

Figs.—Early trees from which the second crop of fruits has been gathered, must be thoroughly cleansed and well watered where the roots have been kept in a semi-dry condition. It is yet early to commence pruning, but all weak growths and those which have performed their work may be thinned out to admit light to promising shoots. These trees, like those grown in pots, must be divested of all intermediate fruits that will not ripen by the middle or end of August. When trimmed and cleansed, the trees should be well hosed with clear water the following morning, especially if strong insecticides have been used. Successional trees still giving a few fruits will require abundance of air by day and a free current by night, otherwise the ripe fruits will spot unless a little artificial heat is used. Where fire heat has been cut off, all watering should be done early on fine mornings, and, the trees being cleansed, syringing may also be dispensed with—damp being the greatest enemy—except on bright mornings. Trees in late, cold houses, now in full bearing, require very similar treatment, barely damping the floors except under promise of a bright day. As these trees carry but one crop, the shoots should not be pinched, as second growths rarely ripen. The shoots should be kept thin, upon the extension principle, and when they reach the extremities, they may be cut out to make room for others. The secret of success is to keep the young growths short jointed, by no means gross, and evenly distributed; all trees showing suspiciously strong shoots should be root-pruned by the middle or end of October.

PLANTS UNDER GLASS.

By T. PATEMAN, Gardener to Sir CHARLES NALL-CAIN, Brocket Hall, Hertfordshire.

Perpetual-flowering Carnations.—Where the plants have been outdoors for the past two months, the time has arrived for placing inside, for preference in the house in which they are to flower. But before proceeding with this work the structure should be well cleansed by scrubbing all glass and woodwork, while the walls should be cleaned and lime washed. There is a danger of the plants being attacked by rust after this date, even where means have been taken to protect them from heavy rains, as the excessive moisture caused by heavy dews is almost sure to lead to an attack, and the only sure way of checking it is to keep the foliage fairly dry. Plants that were propagated early and have filled their receptacles with roots should receive a light dressing of some approved fertiliser specially compounded for Carnations. My experience teaches me to feed the plants little and often, rather than use large doses at one time. Where the former method is practised the growths will keep firm and the flowers will open more kindly during the dull months of the year. Successional batches should be potted on as they require it.

Chrysanthemums.—Plants that are being grown to produce large blooms should have all their buds secured by this date, and in some cases a fortnight earlier. When the buds are secured, means should be taken to prevent them being damaged by earwigs; there are several means of trapping these pests and probably one of the best is to place short pieces of Beanstalks on the plants and blow through them into a jar containing some insecticide each morning. Continue to feed the roots with some approved fertiliser, but here again I recommend using manures in small quantities, rather than less often and in a large quantity. Once in ten days or so is often enough to give dressings, but, of course, the grower must be guided by the weather and by the condition of the plants. All growths should be made secure, otherwise they may be broken out by strong winds, with the resultant loss of many flowers. Keep a watch for mildew and on its first appearance take immediate steps to check this by dusting the foliage with flowers of sulphur, care being taken that this reaches the underside of the foliage. Decorative and single varieties that are being grown to produce disbudded flowers should have all side growths and buds removed by the second week in September, to produce flowers for early November shows; other treatment should be given as recommended for large blooms.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Runner Beans.—These are now bearing well and the tips of the shoots may be pinched out, as this will help to swell-up the young pods. A dusting of some approved fertiliser round the rows will also afford assistance. In dry weather and especially on light soils, a good soaking of water should be given, but not sufficient to chill the ground, or the young Beans will drop. Late-sown Beans will now be coming into flower and will need some attention. These should be examined to training, otherwise the growths will become crowded. Mulch round the lines with short litter.

Autumn Onions.—For spring planting a sowing should be made between this date and the 21st of the month. Tripoli varieties are suitable for this sowing, but Ailsa Craig and Cranston's Excelsior withstand the winter quite well in some districts, although a January sowing and the seedlings pricked out into boxes and planted in April will give better results. Giant Zittau is a good Onion and does well everywhere. Prepare the ground and sow the seeds in the usual way.

Cabbage.—To secure crops for spring cutting, seeds may be sown now so as to have good established plants for planting out by the end of September or early October; Harbinger and Flower of Spring are two varieties that can be depended upon.

Sugar Corn.—Sugar Corn or Sweet Corn has now attained a fair height and for the sake of safety it is a good plan to stake each plant; the foliage is heavy and the plants are easily broken by wind and rain. Mulch the plants, supply them with plenty of water and use the cobs at a suitable stage.

Potatos.—As the Potato haulm turns colour the crops should be lifted at the first suitable opportunity. Choose a dry day for the work, so that the tubers will come out clean. Never leave the tubers exposed for long or they will become green and unfit for use.

Carrots.—Further sowings may be made now for supplying late tender roots; a fair sowing should be made, the one half lightly thinned and kept in the ground all through the winter for the supply of good Carrots in the early months of the year. The stump-rooted varieties should be sown as these grow quickly.

Endive.—A further sowing should be made for later planting. Run the hoe between the rows of earlier batches to keep the soil loose and check weeds.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Bulbs.—Early Roman Hyacinths, Narcissi, etc., for Christmas flowering should be potted or boxed as received, the earlier the better. Hyacinths and Tulips relish a small proportion of old animal manure in the soil, which should be of a light nature, but Naricissi seem to resent such and prefer leaf mould alone—with perhaps a little bone meal should the loam be of a poor nature. After potting or boxing, plunge them under a thick coating of ashes, in the open air for preference, but in a position where heavy rains will not reach them.

Strawberries.—Runners laid down either in pots or the open ground, should now be ready for planting in their permanent quarters. For an early crop the best position possible should be chosen, on a south border, but for second-early or late crops any good land will suit. Unless the ground is very rich, manure must be added, but should not be buried too deeply. Tread the soil very firmly before and after planting, and see that the plants in pots are well soaked at the roots before being turned out. One foot apart, in rows two feet distant, should be a suitable distance, but if the plants are not very strong double rows may be planted one foot apart, with two-and-a-quarter feet between the pairs. Should the weather be dry, the runners should be well watered after planting; all runners should be stopped at an early stage and the ground kept loose on the surface by frequent use of the Dutch hoe, so that good crowns may be built up before growth ceases. John Ruskin is the best all-round variety for early work in the north.

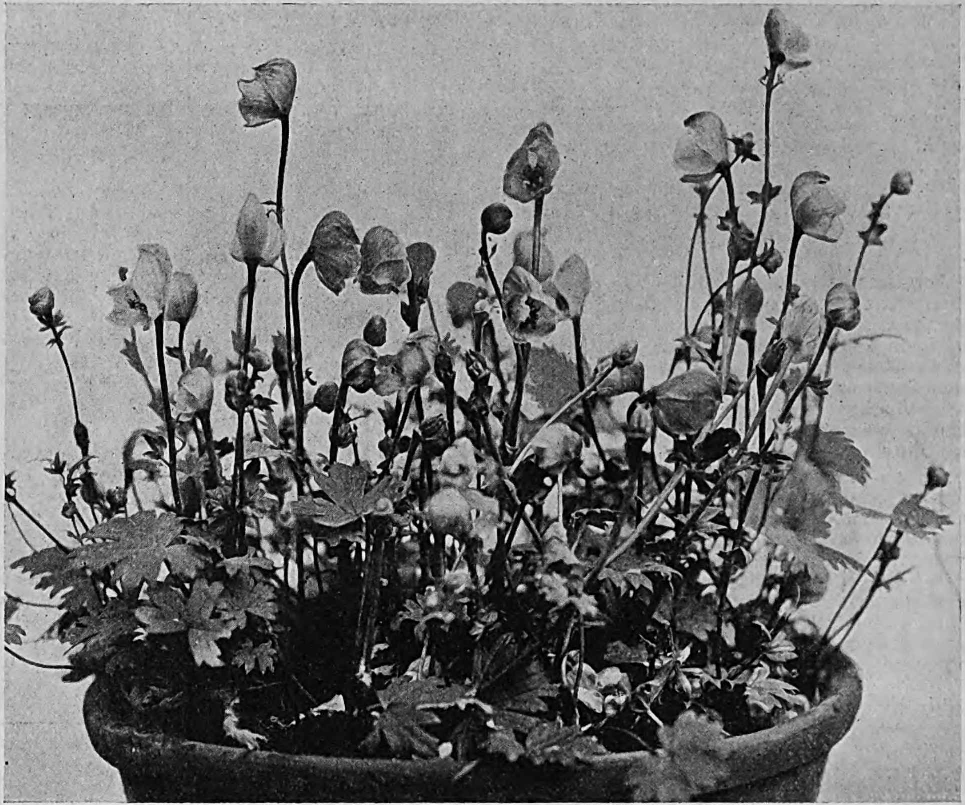

FIG. 73.—ACONITUM CORDATUM.
(see p. 147).

Richardias.—Where these have been rested in their pots they should now be overhauled, the drainage renewed where necessary and a good rich top dressing afforded. If quantities of small crowns are present most of these should be removed, only those likely to flower being retained. They may be kept in a cold frame until danger of frost makes housing a necessity. A thorough soaking with clean water should be given, as an ordinary watering is of little use after such a protracted drying. Stimulants should not be given until growth is free and abundant.

Chrysanthemums.—The flower buds of Chrysanthemums in pots are rapidly developing now and should be secured at an early stage if good flowers are to be obtained. Remove all side or basal growths as they appear. Earwigs are most destructive to the growing points of Chrysanthemums and should be trapped with cylinders of paper, short pieces of hollow stem, or pieces of moss placed at the tops of the stakes. Where room has been left for a top-dressing, this should now be given, using a compost similar to that for potting, and ramming it firm. Where the pots are full of roots, weak liquid manure may be given once or twice a week when the soil is wet. If leaf-miner appears, regular spraying with Quassia extract should keep it in check. September and October flowering varieties in the open should be given a good dressing of an approved artificial manure; a tablespoonful to each plant, hoed into the surface, should prove beneficial.

Mignonette.—Seeds should be sown to raise plants for spring flowering in pots. They may be sown in four-inch pots filled with a compost of loam, cow manure, lime-rubble and sand, and thinned out later to four or five plants, but they are quite easily transplanted, if ordinary care is taken during and after the operation, so that a pan filled with a lighter compost may be used in the first instance, pricking the seedlings out later into four-inch pots in the proper compost. Good drainage is essential at all times, and cool treatment likewise, if clean, sturdy plants are expected.

Cuttings.—Where large quantities of bedding plants are in demand, the present is the most suitable time to raise stock of them. Zonal Pelargoniums, Lobelia, Ageratum, Heliotrope and many other subjects should be placed in boxes of light sandy soil with a layer of pure sand on the top. Pelargoniums root best out of doors in full sun, little water being necessary. The others are best rooted in a close frame shaded during the day, with liberal ventilation at night until growth commences, after which they should have all the air and exposure possible. Keep the growths short by pinching, to encourage the formation of stools, and remove them to a heated structure on the approach of cold, frosty weather.

Vegetables.—Seldom has the Onion maggot been more plentiful, and few plots have escaped entirely. The affected bulbs should be removed and at once consigned to the flames, or some other effective steps taken to destroy the maggots. Onions intended for long keeping should not be surface fed, but where they have been, the practice should now be discontinued. Keep the surface loose to admit air to the soil, and to help the ripening process. Thin out or transplant Lettuces, an early border being chosen at this late period, or where such is not available, cold frames should be used.

TREES AND SHRUBS.

CYTISUS ARDOINII.

CYTISUS KEWENSIS, understood to be raised through the hybridisation of C. albus and C. Ardoinii, is an established favourite for the rock garden, and is universally admired when it is seen trailing over the rocks and giving a wealth of its delightful cream-coloured flowers.

One of its parents, C. Ardoinii, is far from plentiful in gardens, and it is so beautiful that it should find a welcome. It comes from the downs above the Mediterranean, where, we are told, the goats crop it so severely that it does not produce seeds. In the garden it is not subject to the ravages of these animals, and appears to have no enemies to destroy it. It has a charming, prostrate growth, but not really of strong trailing habit, and is, therefore, more suited for the choicer parts of the larger rock garden or for the small one than its hybrid. It likes a sunny place, and is especially pretty planted so as to lie over a large stone, where its branches, plentifully clad with their bright yellow flowers, are shown to advantage. It is also suitable for planting in a sunny retaining wall, and one of the best plants of C. Ardoinii which I have ever seen was growing in such a wall. Its flowering period is given as June, but this year it came into flower in very early May. It is increased by layers or cuttings. *S. Arnott.*

RUBUS DELICIOSUS.

THIS free-flowering Bramble from the Rocky Mountains probably bears the finest flowers of all members of the genus Rubus and a large specimen of it makes a most attractive feature of the garden from the month of June onwards. It is amazing how the Rubi thrive even under conditions of apparent poverty of soil, and R. deliciosus, like its congeners, is not particular as regards soil but likes a sunny position.

As an isolated example, and where it has ample room for development, it is a decided success and needs little attention beyond removing so much old wood as possible immediately after flowering, to encourage the development of current season's growth. Propagation may be effected by means of cuttings but it does not root quite so freely as some other plants of this class and layering is a surer method. *A. M. W.*

GARDEN NOTES FROM SOUTH-WEST SCOTLAND.

THE problem of making a choice among the vast number of new species introduced to this country during the last forty years is indeed a difficult one. Even if it has been judiciously solved, one is often unable to forecast the size to which some of the newcomers may attain, and the space they may claim for due development. The case of Rhododendrons is a simple one, for they can be transplanted at any age and of any size owing to the splendid balls formed by their roots; but the removal of other shrubs entails greater, sometimes insuperable difficulties. I hesitated long before deciding how to deal with a conflict which time had brought about between Pieris formosa and Hamamelis mollis, each over sixteen feet high. Each is the choicest of its genus, but each was interfering with the beauty of the other. At last I sallied forth a few days ago axe in hand and felled the Witch Hazel, feeling very like an assassin as I did so.

Among herbaceous plants not so commonly seen in gardens as their merit would warrant, three species are at their best in August, and, invariably attract favourable notice from visitors. Houttuynia cordata does not appear under that name in the Kew *Hand List*, so it is possible it has received another title. It is described by other authorities as a North American bog plant, but here it thrives vigorously and spreads rapidly by subterranean suckers in ordinary garden soil. It belongs to the Piperaceae or Pepper Order, and holds its blossoms stifly erect at a height of about eighteem inches among dark green and bronze heart-shaped leaves. The tiny flowers are closely packed in cylindrical spikes nearly an inch long, surrounded by four, sometimes five, pure white bracts which look like part of the blossom.

Stokesia cyanea—Stoke's Aster—is another North American perennial, growing some two feet high, but beginning to open its large flowers, borne on a branching stem, long before it reaches that stature. The flowers are of a rich blue-purple hue with a white centre.

Berkheya purpurea is another Composite, formerly known as Stobaea. It is a South African native, but is perfectly hardy here, no whit affected by the late, trying winter. It holds its handsome flowers in clusters on stems two feet high; they have pale purple or white rays round a dark purplish centre and measure about three inches across. The whole plant—winged stems, leaves and involucre—is set with white spines which give it a very distinct appearance.

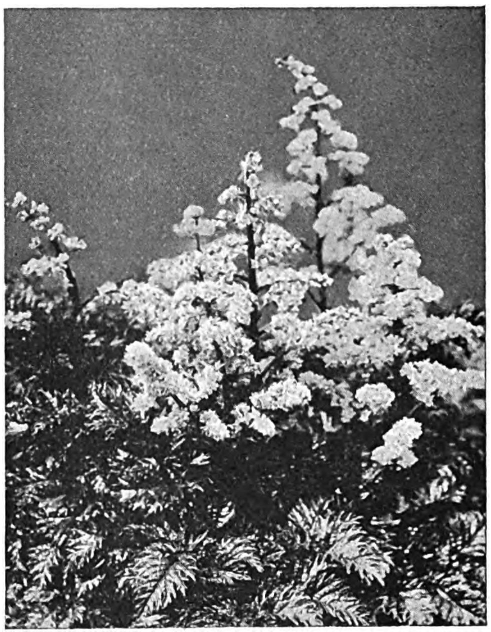

FIG. 74.—ASTILBE CRISPA.

Some herbaceous species of Spiraea are so handsome that one would be unwilling not to have plenty of them, but they are troublesome neighbours for less robust plants in a mixed border, not only spreading into huge clumps, but scattering their seeds far and wide. Such species as S. palmata, S. Aruncus, S. lobata and S. camtschatica are never seen to more advantage than in the wild garden, woodland and by the waterside. Their place in the flower garden may be taken with much advantage by the lovely varieties of Astilbe which have been produced in recent years, and which are often supposed to be a form of Spiraea, whereas they belong to the Saxifrage Order and Spiraea to the Rose Order. This new race of Astilbe is reputed to have originated as a hybrid between Astilbe Thunbergii, and Spiraea astilboides. If that is authentic, it is a remarkable instance of a cross between two plants of different Natural Orders.

Very different in height and habit from the shrubby Spiraeas is S. decumbens from Central Europe. It never grows more than nine inches high, but spreads itself along the ground. We have it here planted high on a retaining wall, a situation which might be thought unsuitable for one of a moisture-loving genus; but it has formed a curtain six feet broad, and is a very pretty object when closely set with circular corymbs of white flowers in June. *Herbert Maxwell, Monreith.*

NOTES FROM A WELSH GARDEN.

DIERAMA PULCHERRIMUM is such a delightful plant throughout the holiday month that those who grow it and miss its flowering must regret having lost one of the most enchanting pleasures of the year. The strain I have has clear rose-pink flowers and very rarely gives a seedling of any other colour. The arching wands, each with nine or ten of the elegantly drooping racemes, are fully five feet tall, and a large group of this excellent plant will give us fully six weeks of its colour and matchless grace. The severe frost of last winter left D. pulcherrimum quite uninjured, even a crop of self-sown seedlings coming through unscathed.

The first of the late-flowering Gentians to bloom here is always a pure white form of the upright growing G. asclepiadea. This is almost over before a deep blue form of the same type adorns its rigid, eighteen-inch spikes with its splendid flowers. Flowering as it does from late July, long before the four-feet stalwarts of the woodland have begun to colour, this is such a valuable and handsome plant that one is surprised it is not more generally grown. A clump or two of a sapphire-blue G. Pneumonanthe, with the delicate silvery-rose of Anagallis tenella flushing the ground round about them, is always attractive near the water at this season.

Sedium pulchellum's rosy-lilac having been invaded by an enterprising bit of Wahlenbergia hederacea, another most harmonious association, in regard to both colour and the nature of the two plants concerned, is at once suggested. Again, the light and airy branches of Lythrum alatum, all ablush with their rosy-purple flowers, might have a worse colour companion than Parochetus communis, whose rich and vivid blue is dappling the fresh green carpet at their feet.

Astilbe simplicifolia, which is the last word in dainty elegance, is one of the those happy little plants which need fear no rivals, not even among some of the hybrids raised from it, beautiful as some of these undoubtedly are in poise and colour. But the Japanese species, if it stands alone at its own time, is preceded by a not less attractive midget, A. crispa. The origin and status of this engaging plantlet I have not yet traced and the Kew *Hand List* does not include it, but the few nurserymen who do are surely in error in classing it as a variety of A. simplicifolia. However, A. crispa (Fig. 74) with its tight little bundle of deeply-cut, crisped, dark-green leaves, hard and leathery as the varnished foliage in a Victorian milliner's window, with its three-inch pyramids of milk-white foam and a Turnip-like root that defies dissection, is a Lilliput of unqualified fascination. It is, moreover, as hardy as an Oak and a most reliable bloomer.

Among the bigger things of the waterside is Spiraea camtschatica which has excelled itself by towering to eight feet, the froth-white plumes being more telling against a dark woodland background than those of the rosy-tinted varieties. Almost equalling it in height are the thick-set, bright yellow spires of Senecio Veitchianus, but from the point of view of colour this great Groundsel must yield place to the splendour of S. Clivorum whose broad-rayed orange suns might rival those of Mutisia decurrens which are blazing with such fiery vehemence in another part of the garden. Astilbe Davidii is among these brookside stalwarts, its virulent colour having the white spikes of Cimicifuga racemosa and others to cool its ardour. An abundance of green also helps to assuage the tyranny of this noble Astilbe's colour and among the leafy things Petasites japonica does not fail to assert its dominance. That this is a dangerous subject to meddle with may be admitted, but there is, to my mind, a symmetry and refinement of line and texture in the monster leaves of this huge plant which are more appealing than anything the Gunneras or Rheums possess.

That cheerful little shrub, Kalmia glauca, seldom fails to produce a late-summer crop of its bright rose-pink blossoms, the only one of its genus that ever does so here. Phyllodoce empetriformis will do the same thing, a concession which only further enhances the value of two Ericaceous shrubs whose unquestionable merit does not seem to have been fully appreciated by gardeners generally.

Among shrubs of medium stature the Hypericums are always a reliable stand-by throughout the later summer. In the generosity of their large, rich yellow blooms, long season of flowering, and the ornamental value of their seed-capsules, often so brilliantly tinted with ruddy hues, they are always admirable. Perhaps the well-known H. patulum and its variety Henryi, H. Hookerianum and the hybrid H. Moserianum, are still unrivalled in their own way. But H. aureum, H. Leschenaultii (now regarded as a variety of H. Hookerianum), H. chinensis, which is on the tender side, and especially the very striking H. rubrostylum, are all shrubs of the first rank. The last-named, which is, I think, unique in the possession of crimson stamens, I first saw in that sanctuary of precious treasures, the Bodnant Gardens.

Desfontainea spinosa needs no eulogies. As an August-flowering shrub it stands alone, an object whose peculiar brilliance will not admit comparison. Regarding the hardiness of this wonderful plant (referred to by *B. O. M.*, p. 109) I can only state that several here, young and old, came through 32° of frost with scarcely any injury last winter. As for the "slowness of growth" referred to by the same contributor, I have not found this a "drawback," nor does the shrub seem unusually long in reaching the flowering stage. I have, for example, specimens raised from cuttings four years ago which are now nearly two feet high and these began to bloom in their third season.

One of the most promising late-flowering shrubs that has come my way for some time is Ceanothus Burkwoodii. This is, presumably, a hybrid, but it is evergreen, with much the appearance of C. Veitchianus. Not only are the inflorescences of good size and a rich violet-blue, but they are borne from July onwards into autumn. To all lovers of this attractive genus the coming of C. Burkwoodii must be regarded as an event of no small moment, and that the shrub is quite as hardy, if not hardier, than most of the evergreen species seems certain.

Hypericums in the rock garden are not less useful during later summer than the taller kinds are elsewhere. H. olympicum, always one of the most striking, can be relied upon to give a blaze of its lustrous yellow and H. o. var. citrinum in a pale, wan ivory is not less pleasing. This latter is so different in habit as well as colour from that usually sent out as H. olympicum that it might well be regarded as a species. There is (or was) an old plant of H. o. var. citrinum in the late E. C. Buxton's garden, with a woody base some three or four inches thick and it annually put up a sheaf of its elegant flowering growths to a height of nearly eighteen inches. These growths, with their very glaucous leaves, are always upright, as they are with my own plants. H. Apollinus is another lovely plant of upright habit, with beautiful silvery-grey foliage and very large, bright golden-yellow blooms. H. crenulatum is always faithful to its reputation for being a good late-season blossomer for a close-up position. If this winsome little plant cannot attain the peculiar fascination which the even smaller H. cuneatum exerts over some of us, it has a more tractable disposition. But H. reptans is undoubtedly the "pick o' the basket" among these trailing species and one of the best of all rock plants for any climate that is not too bleak for it. It is hardy enough, but it seems to dislike excessive wet, especially wet snow, and biting winds. Even so, once it covers a good space, and it will easily drape a square yard or two if conditions are suitable, this delightful species will put up with a vast amount of winter discomfort. Here its broad, dense mat of crimson stems and soft green leaves is adorned with its wonderful golden-yellow saucers, often flecked with red on the reverse, for nearly four months, and the fruit capsules, flushed with a glossy vermilion, provide any quantity of seeds. *A. T. Johnson, Ro Wen Conway, N. Wales.*

PLANTS NEW OR NOTEWORTHY.

NEPETA NERVOSA, Royle.

New border plants with blue flowers are certain of a warm welcome, be they annual or perennial. From the genus Nepeta one does not expect anything of outstanding merit. N. Mussinii is still the most useful, attractive and popular member of the family, in spite of the fact that several species and varieties are now available.

It is not claimed for N. nervosa (Fig. 75) that it is a first-class border plant, but a large bed bearing a perfect forest of stiff, erect-flowering stems, about two feet in height, ending in three-inch to six-inch long spikes of light blue flowers is a sight not be despised. During the hot weather I lost admiration for this species, but this was immediately revived when visiting Mr. Musgrave's garden, for there the plant had been given a shady spot and looked particularly handsome and much more happy and vigorous than I had ever seen it.

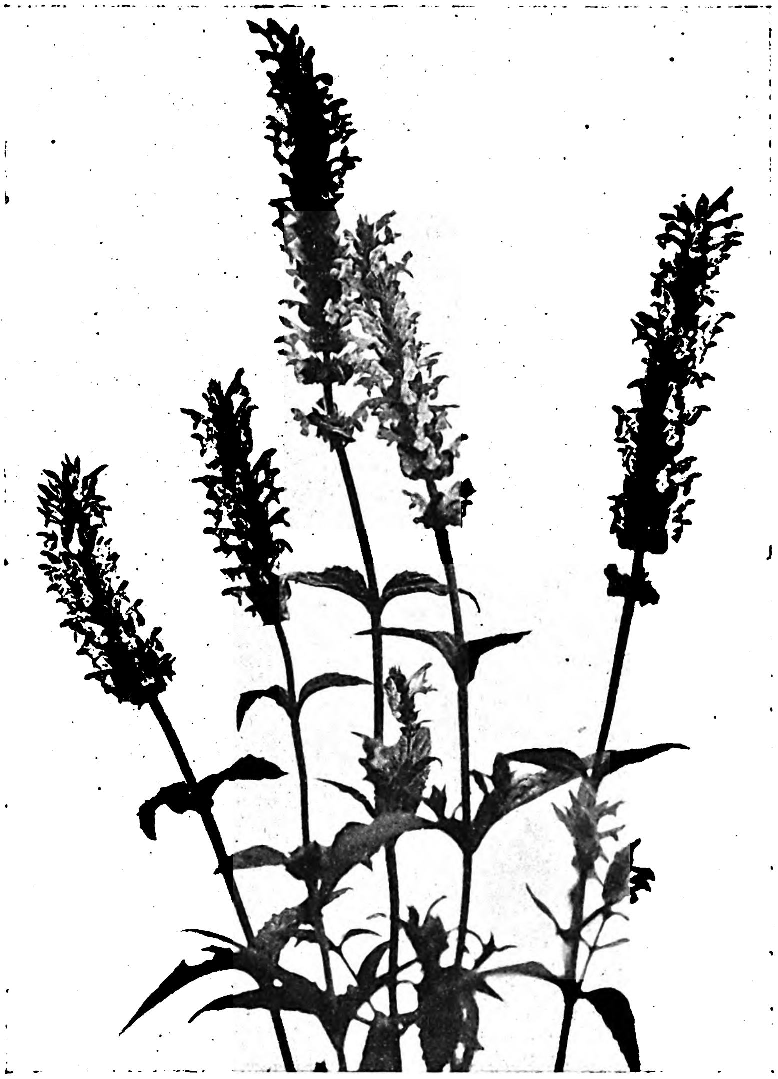

FIG. 75.—NEPETA NERVOSA.

While Nepeta nervosa misses being a first-class plant it is a species well worth cultivating: the flowers are of a clear, bright blue, produced in great quantities. The plant is perfectly hardy, only requiring good cultivation and plenty of water.

It may be propagated easily by division or from seeds and requires nothing in the way of staking. This species was included in the large collection of seeds sent by His Highness The Maharajah of Kashmir and is not found outside of that country.

A short botanical description of the plant is to be found in the second volume of Blatter's *Beautiful Flowers of Kashmir*, p. 192.

ACONITUM CORDATUM, Royle.

The species of Aconites in our gardens are fairly numerous and are all plants suitable for the herbaceous border or the wild garden, ranging from two feet to six feet in height. This newcomer is more likely to find a home in the rock garden and is well worth a place there, as it grows only six inches high. It is quite as free flowering as any of its taller relatives, with flowers quite as showy, and both light and dark forms are produced.

Seeds of this Aconite were received from Kashmir in the spring of 1928 and were sown in the open ground in March. The resulting plants are now flowering where sown, so that the plant has proved as hardy as our native A. Napellus. It is probably new to cultivation and may be described as a dwarf alpine, with tuberous roots; leaves, as its name denotes, heart shaped, incised or cut to varying depths, deep green, one-and-a-half inch to two inches wide; stems branched, carrying from three to five flowers each; very showy when seen in the mass.

It is a native of Kashmir, at high elevations, in grass lands and on the margins of woods. There is no figure of this plant recorded. At tab. 6092 of the *Bot. Mag.* A. cordatum, Royle, is cited as a synonym of A. heterophyllum.

I am informed from Kew that the plant now described and figured here (Fig. 73) is quite distinct from that species, and this will be readily seen on comparing it with the *Bot. Mag.* figure of A. heterophyllum quoted above. *T. Hay, Hyde Park.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the **PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.**

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

HYBRID LILIES.

IN his enthusiasm for the Backhouse hybrids between Lilium Martagon and L. Hansonii, about which he wrote on p. 88 of *The Gardeners' Chronicle*, Mr. R. W. Wallace doubtless forgot for a moment that one swallow does not make a summer, and that the sight of a bed of a hundred spikes of these hybrid Lilies, four to six feet high, no two of them the same, does not belie the truth of the *dictum* that few of the many hybrid Lilies which have been raised from time to time are permanent improvements on either of their parents. Were it otherwise, Lilies of hybrid origin would be found as often in gardens, perhaps, as in the pages of *The Gardeners' Chronicle*. Only two, however—L. testaceum and L. umbellatum—can, as yet, be stated to have gained a permanent place for themselves where Lilies are planted.

None the less, Mr. Wallace's enthusiasm is comprehensible enough in the case of the Backhouse hybrids, and is probably based on surer grounds than that of a friend of the writer, who, after a visit to Luther Burbank's experimental Lily gardens in the closing years of last century, came home a firm believer in the future of hybrid Lilies and convinced that he had seen the beginning of a new era in their history. Burbank's experiments in the crossing of Lilies undoubtedly covered more ground than those of any worker in the field before or since his day. He laid every available species under contribution and hybridised them in such wholesale fashion that at one time he had a hundred thousand in bloom.* He grew them under field conditions and rogued them mercilessly; indeed, it was said of Burbank by a man who worked for him, that "he raises acres and acres of stuff every summer and then has 'em all dug up and burned." According to contemporary accounts, many of Burbank's hybrids were plants of such extraordinary beauty as to excite the enthusiasm of all who saw them; yet, except that such records of his activities as are available are of some value to other workers in the same field, Burbank's work on Lilies has had no practical result so far as gardens are concerned. Of the thousands of hybrid Lilies he raised, there may, perhaps, be one or two types still in existence; the rest have gone the way of such hybrids in general.

In searching for an explanation of the ephemeral character of so many hybrid Lilies we are driven to the conclusion that constitutional weakness has a major share in it. Whether this is due to some underlying cause whereof the significance is not appreciated, or to the happy-go-lucky methods usually pursued by so many would-be raisers of new varieties, is doubtful. It seems tolerably clear, however, that there may be some prospect of success along the lines followed, among others, by the late Mrs. Backhouse and continued by her husband, of mating species within the same sectional group—Martagon with Martagon, Eulirion with Eulirion, for example—rigorously rejecting all that do not pass a certain standard, and, if necessary, intercrossing selected examples again until the desired end has been reached. The process is a slow one and not for those who expect quick results; no two seeds of the same cross are sure to throw the same progeny, and if a desirable variety results from the union of two Lilies, it can only be propagated vegetatively, for seeds of hybrid Lilies cannot be trusted to breed true to type. There is no better example of the truth of this than L. testaceum, which, for all that it is the oldest known hybrid Lily in existence, and has countless generations behind it, refuses to reproduce itself seminally.

In reviewing the supposed qualifications of Lily species as possible parents of new varieties, it might be thought that L. pyrenaicum would make a good sire or mother; it has so tough a constitution that it never fails to welcome the early days of June in southern England, which means that it withstands all the trying changes of which the ends of our winters are capable. It ought, one may think, to mate readily enough with L. monadelphum or L. pomponium, but none of the three seems to have any affinity for the others. Another of the Martagon section which seems to have the making of a good parent is L. pardalinum, but although it mates effectively from a floral angle with both L. Parryi and L. Humboldtii, the hybrids are constitutionally weak. It is much the same when L. Parryi is used as a parent as, for example, in L. Parryi × L. Humboldtii, and L. candidum × L. Parryi. Each is singularly lovely in a totally different way, but frail to a degree. Both L. Humboldtii var. magnificum and L. Henryi have a robust constitution, but do not seem able to pass it on. The former behaves like a mule when mated with L. superbum, which is contrary to the hybridiser's ideas of what is meet and proper.

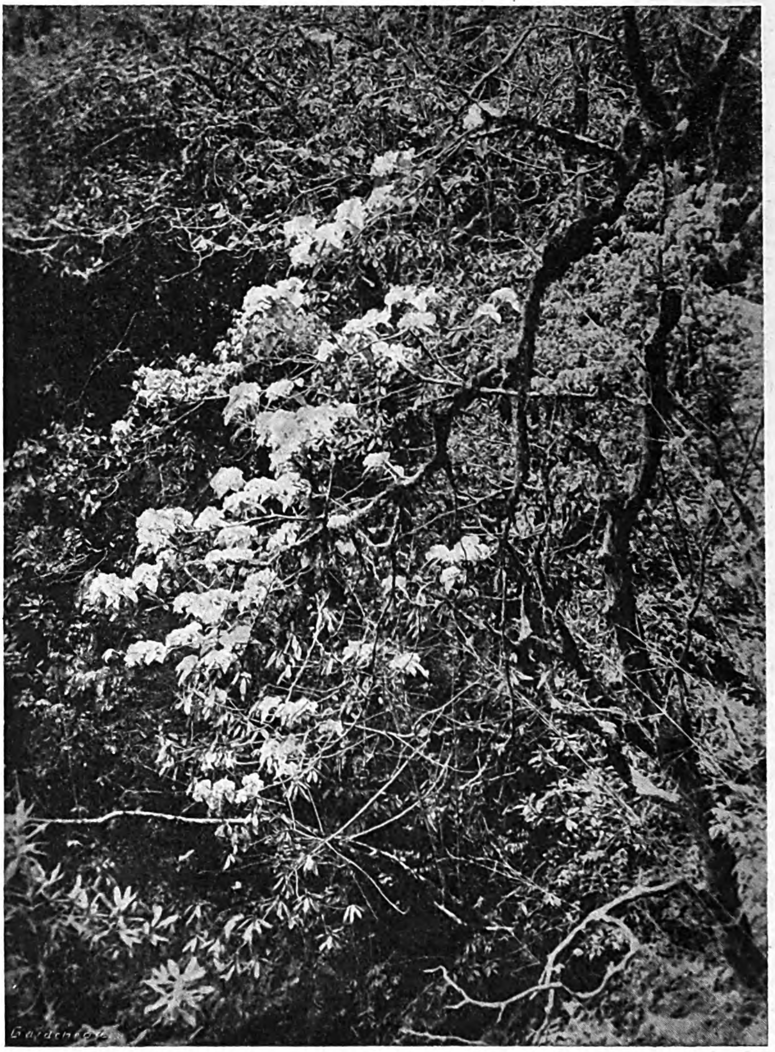

FIG. 76.—VIBURNUM WARDII IN FULL BLOOM.

(Discovered by Mr. F. Kingdon Ward).

Miss Willmott's Lily, which also comes in the Martagon section, should be a prolific parent, but has so far yielded no mixed progeny of importance except the hybrid raised by Miss Preston, of which it was the father and L. Davidii, the reputed mother. This may be described in general terms as a robust-growing and floriferous L. Davidii, with, however, the characteristic, drooping flower pedicel of L. Willmottiae. It is no more robust, however, nor more flowery than L. Davidii is, when happily cultivated, as it is in Mr. Robert Dimsdale's garden at Lechlade, whence I have records of plants eight feet high, and not only in one season. L. Willmottiae, too, is capable of almost equal expansion.

Whether this hybrid fills a gap remains to be seen, for while it bears a general resemblance to its parents, neither of them is difficult to propagate or manage. On the other hand, the hybrid is at a disadvantage in that if it is to remain true, it must be propagated vegetatively. What will probably happen with this Lily, as with that called L. sulphurgale, is that in course of time the seeds will be distributed and the offspring will be confused with the parental types by those who do not know its history. Of all the Martagon section, the typical Martagon Lily seems the most prolific as a parent, and there is something almost improper in the promiscuous way it will mate with others of its section. Then, too, it lends itself peculiarly to the hybridiser's purpose, as it is in bloom in July when the main group of the section is in flower, so that there is ample material on which to work.

The albino form of L. Martagon has long been the sport of the hybridiser and many have been the bastards it has sired or mothered. The Lily called Golden Gleam is one of the L. Martagon var. album hybrids, but in this country it does not seem to have much more staying power than its father, L. tenuifolium, usually shows in English gardens. There is a rich, red-flowered, very downy, seminal form of it which would be worth having were its stamina better. The Martagon Lily, again, is singularly well adapted to the hybridisers' purpose because of the comparatively large

---

* C. Purdy, in *Garden and Forest*, August 14, 1895, p. 328.

number of scales of which the bulb is composed, for each is the prospective mother of one or more little bulbs.

The first (or any) bulb of a hybrid which it may be desired to perpetuate can be stripped of all its scales in the comforting assurance that if they are "sown," each will bear a tiny bulblet; the crop can be increased if the edges of the scales are notched, saw-fashion, with a knife, as a bulblet will usually form in each notch—so anxious is Nature to heal the wound. It is true that the total dismembering of a bulb in this way implies its destruction, but those whose courage is equal to the task have the satisfaction of knowing that what they destroy will be renewed a hundredfold. Those who have not the courage of their convictions can propagate a hybrid or almost any Lily by jerking the stem out of the bulb so soon as the flowers have withered and heeling the lower part of the stem in the ground. Little bulbs will form on the buried stems, and in this case, again, the stem may be slightly notched with a knife to assist the formation of bulblets at the injured points.

It is natural enough that L. regale should have caught the eye of the would-be raiser of new Lilies, but so far it has sired little worthy of notice beyond the hybrid called L. Lahnsteineri, of Scheubel, from which the awkwardly-named variety, L. sulphurgale is derived. The latter Lily has been so regularly raised from seeds, however, that the name has largely lost its significance. Hybrids between L. regale and L. Sargentiae have been named L. princeps and L. George Creelman, but they do not seem to be in cultivation here, and the scores of hybrids of L. regale, which Mr. Amos Perry, of Enfield, showed the writer some years ago, have not yet found a place in the bulb lists.

A union of L. regale and L. japonicum, which Mrs. A. Dudley Ryder made at the writer's suggestion a year or two ago, may possibly instil more stamina into the Japanese species without spoiling its lovely colour. L. centifolium has not, as yet, any mixed offspring to its account as the variety Mr. Bowles has flowered between it and L. sulphureum does not appear to have prospered.

Of the perennial character of L. umbellatum there is, happily, no doubt. Of its kind it seems as good a general purpose plant as anyone could wish. It propagates itself vegetatively in no uncertain fashion, and is as much at home on soils containing lime as on those in which there is none. Then, too, the spring which puts this plant out of countenance must be an exceptionally cold and dismal one. Other hybrids with L. davuricum blood in them are substituted for L. umbellatum from time to time, just as the hybrid itself is commonly sold as L. croceum; but there is no confusing it with any other of the upright-cupped section. *A. Grove.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XXVIII.—Five Alpine Plants.

The rain-drenched mountains of the Indo-Himalayas are not distinguished for their wealth of alpine flowers, other than dwarf Rhododendrons. Even when they are so high as Namcha Barwa, which is over 25,000 feet high, the forests encroach so close to the snow line, and the snow line creeps so far down the mountains, that little room is left for alpine herbs. Therefore we did not expect to find a great variety of alpine herbaceous plants on Kaso, or its neighbours, which barely attain 17,000 feet altitude; Rhododendrons we might reasonably hope for, but not that carpet of alpine flowers which is such a feature of the drier ranges to the north and east. A further handicap was the sameness of the rock everywhere, dark granite and closely banded gneiss. In the Seinghku valley in 1926 I had the good fortune to find a belt of limestone running right through the high country, and this had a flora all its own, greatly augmenting my discoveries; but there was nothing of that sort in the Delei valley.

However, a few alpine and sub-alpine plants of special interest may be singled out for mention in this chapter, and first of all I will deal with the yellow Omphalogramma, as I dubbed it originally, which was the commonest of all. This strange plant grew scattered along the ridge beneath Bamboos and Rhododendrons, between 10,000 and 12,000 feet, that is to say, in the Abies forest. It asks for only moderate shade, often growing on the moss-covered trunks of fallen trees, but it shrinks from water other than that which descends from above; in fact, it is a typical woodland plant like Anemone nemorosa, say. The flowers appear while the leaves are still very immature, opening towards the end of May in the lower altitudes, and are bright yellow, nodding, borne singly at the end of the tall scape, although the crown of leaves may bear two or three separate scapes. At first glance the flower recalls a Lloydia, although this superficial resemblance is quickly lost on dissection, when the plant is immediately recognised as belonging to the Primula family. It is not, however, quite a Primula. The seven sepals, petals and stamens suggest rather Omphalogramma, an opinion strengthened by the bluntly heart-shaped, petiolate leaves and solitary flowers without bracts, and almost confirmed by the urn-shaped capsule.

But it is this same capsule, no less than six inches long and very slender, which puts us on our guard, and partially prepares us for the great surprise. For the seeds are little brown rolypolies with finely-pitted skin, which rattle gaily at the bottom of the tube! No, you cannot call such a plant Omphalogramma—that would be too absurd; these seeds are nothing like the flat-winged seeds of O. Souliei for example, and,

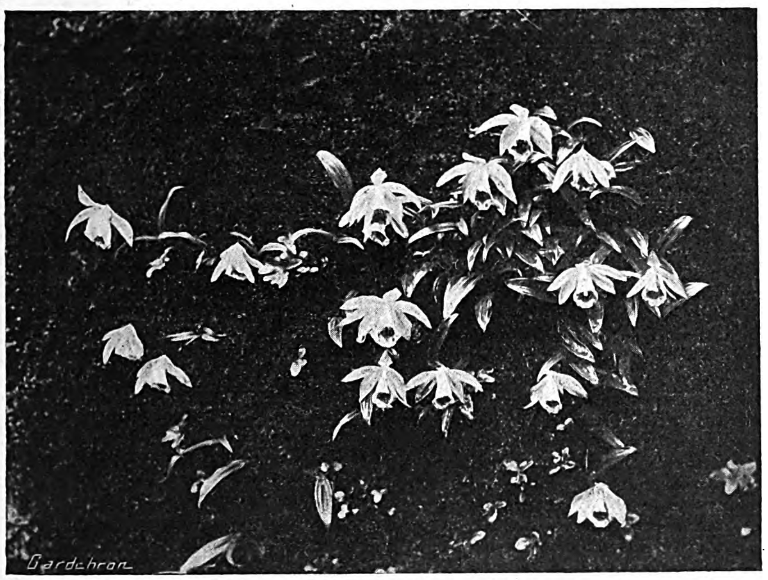

FIG. 77.—A PURPLE PLEIONE.
Found on cliffs at 10,000 feet altitude.

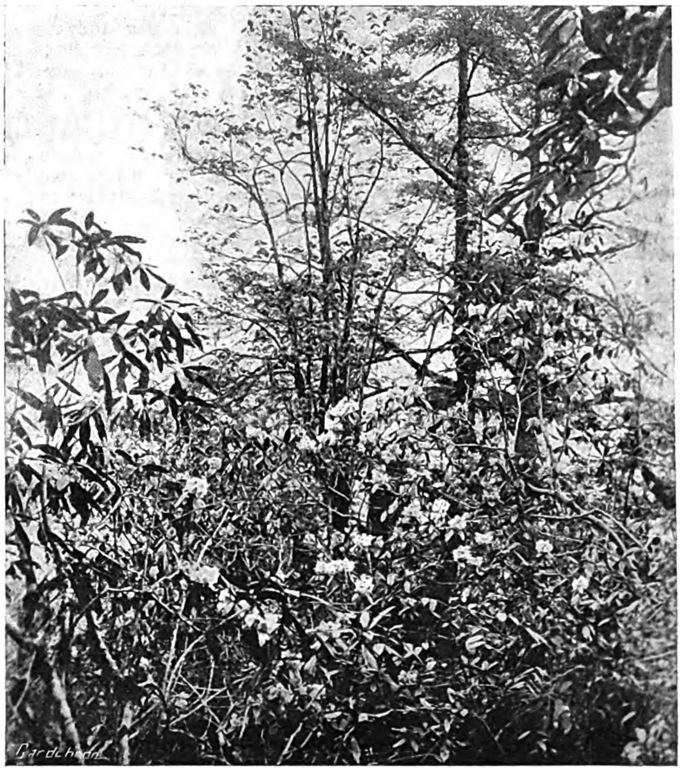

FIG. 78.—RHODODENDRONS IN BLOOM ON THE KASO RIDGE.

---

* Previous articles on Mr. F. Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; March 2, 16, 30; April 13, 27; May 18, 25; and June 1, 15 and 29, Vol. LXXXV; July 13, 27; August 10, 1929.

truth to tell, neither is the long, terete capsule, with its few seeds trapped in the bulged base (where they may be found nine months later), like the wide-mouthed urn, crammed with seeds of O. Souliei ; although there is a family likeness here, and when the capsule of our plant is ripe, the tip slides off as though cut with a razor, leaving the rim to grow teeth like an Omphalogramma.

Nor do these seeds resemble those of any Primula known to me, coming nearest, perhaps, to the typically-rounded lozenges of the 'Sikkimensis' Primulas, whose long, projecting capsule—shared by some of the 'Nivalis' Primulas such as P. muliense, also recalls that of our plant. It occurred to me—and Professor Wright Smith had already suggested the same thing—that this yellow 'Omphalogramma' might be a Bryocarpum, B. himalaicum being a monotypic genus from Sikkim, a plant I did not know. On arrival in Calcutta I looked up the fine series of this unique species in the herbarium and found that this puzzling plant from the Delei valley, which at one time I had thought to put in a new genus, was in fact a Bryocarpum, although perhaps not B. himalaicum.

The steep flanks of the ridge were seamed with gullies, and those which began their career at 11,000 feet or so, were crammed down below, where visible water first appeared, with alpine meadow flowers such as Trollius, Caltha, Astilbe, species of Polygonum, Aconitum and many other plants.

It was in one of these gullies that I first noticed a 'Sikkimensis' Primula with small, rounded leaves on distinct petioles, as it might be P. firmipes or P. reticulata. Eagerly I watched the buds, at this date still snuggled down among the flanged bases of the leaf stalks, and when about mid-June they began to stretch themselves, showing a chocolate lining to their green jackets, I expected a rich prize. A few days later the first flowers shook themselves free. They were of the ordinary 'Sikkimensis' type, rather slender, of a rich maroon-red, and deliciously scented. There was, indeed, an air of daintiness about the whole plant which was quite fascinating—the tidy leaves, the trim scape negligently swinging its tassel of slender, red flowers, everything neat and graceful. Moreover, this species is as unlike any of the other red-flowered 'Sikkimensis' Primulas as one "Sikkimensis" can be unlike another. It bears no resemblance whatever to 'Ruby' (P. Waltonii), and even less to P. microdonta var. alpicola (rubra), differing in foliage, in flower, in stature, and in its complete lack of meal. Nor is it any more like P. secundiflora, or P. vittata. Its nearest and dearest seem to be P. Florindae, P. firmipes, and P. reticulata ; and if extremes mate, and it can be persuaded to infuse some of its breeding and sanguine complexion into P. Florindae, the resulting mulattos should be worth while.

On the gravelly flanks of the ridge at Iris Cliff there flowered at the beginning of July a second species of Nomocharis. It was not perhaps a beauty, being woefully spotted as though a fierce rash had erupted all over its damask petals, ruining its complexion, but it was undeniably a handsome plant. Unlike those of the red Nomocharis, its flowers opened wide and flat, being about two inches in diameter, the petals, three and three, sharply pointed. It was a tallish plant, fully two feet high when the first bloom opened, and it would probably put on another foot to help carry its full load of half-a-dozen flowers. The satin ground-work of the petals was a faintly clouded white emblazoned with spots and splashes of sinister purple ; and the little column of foxy-orange anthers contrasted keenly with the morosely dark centre. The only species of Nomocharis this recalled to me was one I collected many years ago on the Pine-clad hills of Yung-ning, in far away Yunnan, and referred, I believed, to N. Mairei, It would be odd to find N. Mairei in the Mishmi Hills ; more likely it is a new species.*

Then there was that wonderful little rock Rhododendron which I have named 'Rock Rose,' one of the brightest and sprightliest of creepers. It forms a close mat of long, thread-like stems, branching repeatedly, the flowering shoots ascending an inch or two. The leaves are few, crowded at the ends of the twigs, leaving the stem bare ; but all this is covered by the large, pale purple-spotted corollas, borne singly in great profusion, each about an inch-and-a-half across. This species belongs to an assemblage which is difficult to place. The first species met with was 'Purple Emperor,' collected in the Seinghku valley in 1926 ; but that has much smaller flowers, although the two are obviously related. The funnel-shaped corolla and very laxly lepidote leaves forbid alliance with the 'Saluenenses,' to which the habit of these creeping rock mats points ; and for the present they are best left in a group by themselves.

Lastly, the gamboge 'Nivalis' Primula of Boggy Valley, a blond rival of the 'Tea Rose' Primula—the rose-coloured Seinghku valley form of P. Agleniana. The gamboge Primula showed mixed affinities. In general appearance, in the shape of its large flowers, and to some degree in colour and in the restrained development of the truss, it recalled the 'Daffodil Primula' of the Doshong La (Tibet, 1924). But it was a richer and more constant yellow than that 'beautiful devil,' without its fragrance. And the Daffodil Primula never developed more than two flowers on a scape, usually only one ; the gamboge Primula usually developed two or three flowers in a truss, and we collected one plant, out of the thousands seen, with five. In this respect, therefore, it stands mid-way between the shy 'Daffodil' with its one or two flowers, and the exuberant 'Tea Rose' with its fat bunch of eight or ten. But the long, strap-shaped leaf of the gamboge Primula, with its deeply saw-edged margin, was the leaf of the 'Tea Rose' Primula, or of true P. Agleniana, over again.

This glorious 'Nivalis' spread a cloth of gold over the one-time snowfields of the northern slopes of Kaso, where a fortnight earlier P. calthifolia had first seen the light of day. The ground was a tenacious bog, coal-black when wet, and into this unpromising looking vegetable clay, the Primula thrusts its long, radiating roots from the base of the etiolated bulbous rootstock. The plants probably live quite four or five years before they can produce a really good head of flowers ; but as they are buried under an immense weight of snow for at least seven months in the year, they do not really have to work so desperately hard. While in flower, their life is one long aquatic sport. But although we jeer at their conception of happiness, it suits them to such a degree that, on the bleak, boggy, northern slopes of Kaso, there flower every June and July tens of thousands of the gamboge Primula. *F. Kingdon Ward.*

HARDY FLOWER BORDER.

COREOPSIS VERTICILLATA.

One of the most graceful of the Composites for autumn flowering is the North American Coreopsis verticillata, a plant which has been introduced for very many years. The figure in the *Botanical Magazine,* which purports to be C. verticillata is, however, a representation of C. delphinifolia (*Bot. Mag.*, t. 146). C. delphinifolia is a taller and less graceful plant than C. verticillata. It is strange that this latter species is so little known, as the writer has found from the many inquiries which he has had regarding its name, especially from people who have seen it in his garden. It grows well in ordinary loam, and forms a very neatly-shaped bush about two feet or a little more in height, composed of a number of stems bearing many leaves arranged in verticillate order around the stems. The plant bears a great number of moderate-sized, clear yellow flowers well distributed over the handsome bush. The general effect is somewhat approaching that produced by a Nigella of taller habit than usual and with yellow flowers.

Coreopsis verticillata is stocked by many hardy plant dealers at a moderate price and may be planted either in autumn or spring. It may be raised from seeds, but, as the plant is of free, although not aggressive, growth, it is easily increased by means of division in spring or autumn. I have always grown it in borders having a fair amount of sun. It begins to flower in the end of July and lasts for a considerable period in bloom. *S. Arnott.*

SYMPHYANDRA HOFFMANNII.

With the exception, perhaps, of the beautiful S. pendula, the Symphyandras have never enjoyed a recommendation sufficiently warm to ensure their popularity as garden plants. But, in addition to the species mentioned, S. Hoffmannii is a really good thing, so good for the post-Campanula days of August that one is surprised it is so little known. From a bold tuft of roughish leaves, which looks exactly like a promising Canterbury Bell, flower stalks appear about mid-summer. These grow to some eighteen inches long and bear throughout the later weeks of the season a succession of flowers in a firm, clear white. The individual blossoms, if they have some resemblance to those of the familiar biennial mentioned, are refined enough to assert their superior distinction, and a strong plant, producing several of these flower-bearing stems, is decidedly handsome.

S. Hoffmannii likes a well-drained, gritty loam and, unlike many others of its kind, prefers rather a cool, partly-shaded spot. This species came from Bosnia in 1884. It is quite hardy and perennial, shadowed as it may be by the menace of biennialism.

SALVIA DICHROA.

This is an old plant, being known to our gardens since 1793. It is a robust herbaceous perennial and if it can scarcely rival the best of its class there is a distinction and charm about its four-feet spires of lavender-blue and white flowers which should have earned it a wider recognition. The rough and crinkly, Mullein-like leaves are a deep green with a purple tint on the mid-rib, and the branching flower stalks, stained with the same hue, are elegantly tapered and held stiffly upright.

Salvia dichroa blooms a good deal earlier than many of the border Sages, a succession of flowers being maintained from the beginning of June for several weeks. The individual blooms are fully an inch long and the seeds, which are yielded abundantly, afford a ready means of increase. A clump of Salvia dichroa looked remarkably well in a mixed border this summer with yellow Verbascums as companions. *J.*

PENTSTEMON GLABER AND P. ANGUSTIFOLIUS.

There are, apart from the brilliantly and variously-coloured Pentstemon hybrids, many beautiful species which are grand garden subjects, and among them Pentstemon glaber ranks high, being suitable for planting in groups either on the rock garden or in the front of the herbaceous border, as it is of comparatively dwarf stature, seldom attaining more than one foot in height, although the individual flower stems may be anything up to two feet in length.

Pentstemon glaber comes from the western United States, but in my garden it has proved quite hardy and is a good perennial, provided it is not subjected to wet and dank soil conditions in the winter. Perhaps it is best grown on the rock garden, certainly it is an ideal subject for such, for it provides a wealth of bright colouring at a season of the year when the majority of the alpine plants have ceased to display their floral charms, and rock garden conditions would appear to suit it best. It should be planted in a sun-kissed spot, in rather light and well-drained but moderately rich soil, and under such conditions will form a clump of short-stalked, entire smooth and slightly waved, glabrous and more or less glaucous foliage, and will produce during

---

* Mr. W. E. Evans informs me that this is N. aperta, a species hitherto known only from a small area in western China. N. aperta, however, is not closely allied to N. Mairei.

July and August numerous slender, leafy, erect or semi-prostrate stems terminating in dense inflorescences, the wide-mouthed, tubular flowers one inch or more long, and bright amethystine-blue in colour, shading to violet or rosy-purple, being produced in opposite clusters of six or more in the axils of leaf-like bracts. P. glaber is figured and described in the *Bot. Mag.*, t. 4,319, under the name P. Gordoni, the figure being of a plant raised from seeds collected by a Mr. Gordon in the Platte River valley, on the east side of the Rocky Mountains. There are several distinct forms of P. glaber in cultivation, although it is doubtful if any of them is an improvement on the type, which is a plant of rare charm; certainly those in which the purple colouring is developed at the expense of the bright, clear blue are inferior to it. However, some of the varieties are worthy of recognition, notably var. cyananthus. This variety, which was previously classed as a distinct species, is taller and rather more vigorous than the type, and is less glaucous, the leaves are broader, while the blue flowers are borne in dense clusters. P. g. var. cyananthus (sometimes given as cyanthus) is found in the Rocky Mountains and in Colorado and Utah; it is figured in the *Bot. Mag.*, t. 4,464, as P. cyananthus, and may be regarded as equal in decorative value to the type.

The variety alpinus is described as having narrow or broadly-lanceolate leaves, and may also be distinguished from the type in that the inflorescences are shorter and fewer-flowered. It is limited, apparently, to the Rocky Mountains and is regarded by some authorities as a distinct species. P. g. var. rosea is of about the same height and habit as the type, and has rose-coloured flowers, while the variety splendens grows to a height of about two feet, and has dark blue, richly-coloured blooms. The other variety of P. glaber worthy of note is var. speciosa, which, like several of the other forms, was primarily regarded as a distinct species; it has bright blue flowers, shaded with purple. Some, or all of these varieties are worth planting if space can be found for them.

Another beautiful Pentstemon, which ranks with the foregoing species as one of the gems of the genus, and which also has come to us from across the Atlantic, is P. angustifolius, perhaps more commonly known under its synonym P. coeruleus. It is a lovely plant indeed, of varying height—from one to two feet,—with glossy, grey-green, narrow foliage and producing masses of leafy stems, during the same period as P. glaber, which are crowned in their upper parts with closely-packed, one-sided spikes of lovely flowers, clear, rich sky-blue, shaded with rosy-lavender to a greater or lesser degree, but withal very handsome and striking; they vary in colour somewhat, some plants having lilac or almost white blooms.

Like P. glaber, this species is most at home in English gardens when planted in a sunny position on the rock garden, in rather stony and well-drained, light, but amply enriched soil. Both the species may be increased by seeds, or by the careful removal of offshoots, which are best potted and wintered in a cold frame. *M. W.*

ALPINE GARDEN.

SAXIFRAGA CAESIA.

There are many more appreciated little Kabschia Saxifrages, yet there are few which would induce us to deny the pleasure of cultivating S. caesia in order to give space to another of the race. Fraser tells us that "it is the commonest of the choice wild Kabschias, and always one of the most delightful." It was in bloom in my moraine in early June, but it deserves notice on account of its foliage even if it never bloomed at all. It creates small, crowded mounds of tiny rosettes, closely packed together, and made up of little, recurving leaves, rather broad-shaped and charmingly dotted with lime. From these emerge slender, thread-like stems three inches or so high each bearing several attractive, milk-white, starry flowers. It is charming here in the moraine, but grows perfectly well on rockwork. The species has a decided preference for lime and a rather cool place, but the former it can do without and the latter is not so much needed in the colder districts of this country. The form major, which I do not possess, is very fine indeed.

POLYGONATUM OFFICINALE.

There is a dwarf Solomon's Seal, which is a native plant, but is none the less beautiful because of that. Although a native, it is quite rare in gardens, but those who have had it once and lost it look back with regret upon the days when this attractive little plant gave some beauty to their gardens. It is one of the plants which are to be found in copses below the limestone cliffs, and in the cracks of the same rock higher up. Yet it is rare in gardens and seems as rare in nurseries, at least if one may judge from its absence from most catalogues. I had it years ago from a true lover of flowers, and grew it for a good while but lost it through removal.

It resembles, yet is unlike, the ordinary Solomon's Seal of gardens, and it is only about eight inches high. P. officinale has pale green leaflets folded back, and from each pair there hang out two large, whitish-green bells. It flowers quite freely and is a good plant for near the front of the border or for the rock garden. I have never seen it seed, but it may be increased by division. One would consider from its native habitats that it was a lover of lime, but it thrives quite well without it, as the writer has found.

CAMPANULA LAURII.

Campanula Laurii, stated to come from the Greek Islands, has not been long finding its way into gardens where the best rock plants are appreciated. The family, although to some degree subject to the fluctuations of demand, as new plants come into cultivation, can never be neglected, as it is one of the highest importance among alpine flowers. The species, hybrids and varieties of Campanula comprise so many lovely plants that it is difficult for a new one to make its way unless it has some outstanding beauties.

C. Laurii appears destined to remain a favourite and to be included in most good rock gardens. In habit it is after the fashion of C. rotundifolia, but its flowers, instead of drooping, are erect and open. They are of a pleasing shade of lavender. They are also of good size, being in many cases about an inch across. This Campanula flowers exceedingly profusely, and a good plant is a sheet of bloom at its zenith in late summer. C. Laurii, which is hardy, may be raised from seeds or propagated by division or cuttings. The soil generally afforded to rock plants will answer well for C. Laurii. *S. Arnott.*

LINUM VISCOSUM.

This is a plant of much distinction and charm, but it is not one that is often grown, and it is seldom seen doing very well. It came to us over a century ago from Southern Europe and is, as Farrer reminds us, one of the few Flaxes which rather shrink from the hottest and driest places. The same author writes that it is rather a spare grower, with no more than one or two stems to a crown, and this is no doubt a common characteristic.

I have seen the plant make quite a sheaf of growth in addition to bearing an abundance of flowers, that being on a stony hillside, with enough underground moisture and other essentials to constitute a natural moraine. These flowering stems rise to about a foot. They are set with broad, oval leaves and break into short branches at the summit, each producing several flowers. These latter, in my own plants, are a clear rose with lilac shadings and a satiny sheen, but there is a good deal of variability in the colour, some tending to blue, others to mauve. L. viscosum seems hardy enough and is valuable on account of its flowering in July and August. The whole plant is sticky, or viscous, as the specific name suggests. *North Wales.*

THE GENUS PRIMULA.

(*Continued from p.* 128).

PRIONOTES (Balf. f.). Karo P.
(Sikkimensis).

A handsome perennial sub-species of P. Waltoni (Watt) resembling a purple-flowered P. sikkimensis with a sparse tuft of thin, non-mealy leaves about seven inches long, with elongate-oblong or narrowly-elliptic, blunt or pointed blades abruptly wedge-shaped at the base, or gradually tapering to an obscurely-winged stalk, at times slightly dilated below; margins furnished with regular, saw-like teeth; under surface paler than the upper. Flower stem nine to fourteen inches tall, coated with yellow meal at the tip, slender, bearing a terminal, many-flowered umbel of purple, drooping, somewhat reflexed blossoms on thread-like, more or less mealy stalks. Corolla concave, about five-eighths-of-an-inch across, sprinkled with yellow meal and divided into five rounded or oblong, erect, slightly notched lobes; tube cylindrical below, funnel-shaped above, about twice as long as the calyx. Flowers in July.

Grows near Karo-La, in Tibet, in damp situations at about 16,500 feet above sea-level.

Culture: As for P. sikkimensis.

PROLIFERA (Wall). Indian Imperial P.
(Candelabra).

A deciduous perennial closely allied to, if not a form of, P. imperialis. It produces a robust tuft of egg-shaped, lance-shaped or elongate-egg-shaped, spathulate, blunt leaves from eight to sixteen inches long, tapering to a broad, winged stalk; margins entire or sharply toothed; upper surface more or less smooth, underside smooth or downy, non-mealy. Flower stem stout, twelve to eighteen inches tall, bearing from two to four superposed umbels of numerous yellow flowers. Corolla about three-quarters-of-an-inch across, divided into five broadly heart-shaped, notched lobes; tube cylindrical, twice as long as the calyx, with a ring in the mouth. Introduced in 1884. Wall in *As. Research*, Vol. XIII, 372, t. 3.

Grows in damp places on the Khasia Hills, in north-eastern India, at from 4,000 to 6,000 feet above sea-level.

Culture: As for P. imperialis.

PSEUDOBRACTEATA (Petitm.). False Bracteate P.
(Bullatae).

A sub-shrubby, evergreen species with a thick, woody, branching rootstock clothed with the dried remains of previous seasons' foliage. It forms tufts of oblong, blunt leaves about one-and-a-quarter inch long tapering to narrowly winged stalks about equalling the blade in length; margins edged with sharp teeth; underside coated with white meal. Flower stem half- to three-quarters-of-an-inch tall, bearing an umbel of four to six yellow blossoms on short stalks. Corolla concave, about half-an-inch across, with broadly heart-shaped, notched lobes; tube twice as long as the calyx.

Grows in the clefts of rocks and on the ledges of cliffs near Batang, in Yunnan, western China.

Culture: As for P. Forrestii.

PSEUDODENTICULATA (Pax). Chinese Toothed P.
(Denticulata).

This species, which is best treated as a biennial, produces a rosette of numerous, non-mealy, lance-shaped or linear-oblong, stiff leaves, blunt or pointed at the tip, tapering to a winged stalk, in all from three to four inches long; margins recurved, coarsely toothed or almost entire. Flower stem six to twelve inches tall, stout, covered with white meal upwards and bearing a flattened, many-flowered head of rosy-lilac, fragrant blossoms with an orange-coloured eye. Corolla about five-eighths-of-an-inch across, concave, with broadly heart-shaped or broadly wedge-shaped, notched lobes; tube slender, cylindrical, about as long as the calyx, with a ring in the throat. Introduced in 1908. *Gard. Chron.*, 1913, Vol. LIII, p. 264, Fig. 113.

Grows in damp places in mountain valleys in the regions of Mentze and Tali, in Yunnan, western China, at 7,000 to 8,000 feet above sea-level.

Culture : As for P. denticulata.

PSEUDOELATIOR (Kurnetzow). False Oxlip. (Vernales).

A handsome sub-species of the true Oxlip, with tufts of hairy, much wrinkled, rich green leaves two to four inches long, with oval blades, heart-shaped or abruptly truncate at the base, with broadly winged stalks ; margins furnished with regular, rounded teeth ; underside paler than the upper. Flower stem three to six inches tall, erect, downy, bearing a many-flowered umbel of yellow blossoms. Corolla about three-quarters-of-an-inch across, with heart-shaped, shallowly-notched lobes.

Grows in damp, alpine meadows and on the margins of woods, in the central and western Caucasus, at 6,000 to 10,000 feet above sea-level.

Culture : It requires good, rich, fibrous loam in a damp spot.

PSEUDOGLABRA (Hand.-Mazz.). False Smooth P. (Farinosae).

A slender, deciduous, perennial species apparently of but little decorative value, with a short, stout rootstock emitting many fibrous roots and a sparse tuft of deep green, erect leaves, with egg-shaped or egg-shaped-oblong blades, half- to one-and-a-quarter-inch long, usually rounded at the tip and gradually tapering at the base into slender, narrowly winged stalks, usually exceeding the blade in length ; margins edged with blunt, curved teeth ; both surfaces covered with minute, sub-sessile, meal-producing glands. Flower stem four to six inches tall, slender, non-mealy, bearing a many-flowered head of rose or violet-coloured blossoms, on extremely short, thick stalks. Corolla flat, usually less than a quarter-of-an-inch across, divided into five broadly obovate, bifid lobes ; tube broadly cylindrical, about equalling the calyx in length, with an obscure yellow ring in the mouth. Not in cultivation.

Grows in damp, rocky hollows above the temple of Huang-lung-si, at Dongrergo, in northern Szechuan, at about 15,000 feet above sea-level, on the borders of the melting snow.

Culture : As for P. farinosa. *A. W. Darnell.*

(*To be continued*).

THE CULTIVATION OF NEW ZEALAND PLANTS IN BRITAIN.*

(*Concluded from p.* 129).

Raoulia is represented only by the sub-alpine and lowland species, such as R. australis, R. subsericea, R. glabra. The high alpines are absent, and might be very difficult to grow. R. eximia is often tried in vain.

Helichrysum is fairly well represented. H. bellidioides is commonly grown and H. Selago and H. microphyllum are sometimes to be seen. I have not found H. coralloides or H. Youngii here, and H. grandiceps (" Edelweiss ") has not, I think, been successfully grown yet. H. dimorphum, that wonderful discovery of Dr. Cockayne's, does well at Edinburgh.

Celmisia has naturally attracted much attention, and most of the larger species are in cultivation in specialists' gardens, such as C. coriacea, C. holosericea, C. Hookeri (or verbascifolia), C. spectabilis, C. densiflora, C. prorepens, C. Monroi, C. McKaui and C. petiolata. But few or none of these are in general cultivation or stocked by nurserymen, and I miss altogether the smaller, yet very ornamental, species, which would be invaluable for the rockery, such as C. Hectori and C. argentea. C. viscosa is at Edinburgh.

Haastia is completely wanting here, although I have myself sent seeds of H. recurva to this side. They would, of course, be very difficult to grow, even in " moraine," and hitherto no one seems to have succeeded with any of our three species.

Epilobium has also been comparatively neglected, but a few of our more handsome species are grown (although not generally). I have seen E. chloraefolium E. macropus, E. pedunculare and E. nummularifolium most frequently, and in the Edinburgh rockeries E. melanocaulon and E. pictum, both unlabelled and perhaps accidentally introduced with other plants ; also E. nerterioides.

Gentiana is one of the great surprises. The only New Zealand Gentian that I have seen here was the humblest of them all, G. novae-zelandiae, sent to Mr. Loder by Mr. Edgar Stead. The absence of rich colour, of course, renders our species less attractive than those which are so deservedly popular here, yet such plants as G. corymbifera and G. saxosa (to mention only two) are surely worthy of a place in any garden if they can be brought to anything like their true form in this climate. G. saxosa, as a maritime species, would probably prove tender.

Myosotis is another disappointment. I saw M. Traversii at Edinburgh although modified and hard to recognise and M. decora, sent by Mrs. Poulton to Mr. Millard and also grown by Mr. Ingwersen. One feels sure that such species as M. macrantha and M. concinna would meet with a warm welcome and there are others which suggest themselves also. Kew has M. Traversii, M. capitata and M. antarctica only.

Aciphylla is not a very attractive genus, but A. Colensoi is much admired and often grown, and A. squarrosa also is found here and there. I have seen no others.

Carmichaelia, though not exactly ornamental, is grown a good deal, C. Petriei, C. grandiflora, C. flagelliformis, C. Williamsii (where possible), and C. Enysii have been seen in several places. The allied Corallospartium and Holospartium (two species) have also been seen here and there. Chordospartium Stevensoni was grown by Mr. Boscawen at Ludgvan, but it had not flowered when he published his paper on our plants in 1923.

Coprosma is very well represented. In one place or another I have listed C. acerosa, C. parviflora, C. rotundifolia, C. propinqua, C. rugosa, C. Petriei, C. ramulosa, C. serrulata (Wakehurst), C. robusta and C. Baueri (Tresco).

Hoheria, Plagianthus and Gaya are quite extensively cultivated—all our species, I think. Gaya Lyallii and G. ribifolia are especially popular. Kew can only grow Plagianthus and Hoheria under cover.

Pittosporum has been much cultivated and most of our species are to be seen in several places. P. Dallii does very well, at Ludgvan in particular ; P. crassifolium is found most useful as a shelter-belt plant at Tresco ; several forms of P. tenuifolium are in cultivation, especially in Guernsey. Uncommon species like P. patulum, P. Ralphii and P. Fairchildii have been listed here and there.

Nothofagus is not so generally grown as one would expect. All our species have been seen, however, and at Tresco, Wakehurst and Ludgvan they grow splendidly. Aldenham has been found too cold for them ; so has Kew.

All our Cordylines are grown in the west. At Tresco, in addition to the remarkable hybrid already mentioned, there is a beautiful copper-coloured form of C. australis which comes true from seeds. C. australis and C. indivisa are stocked by nurserymen in the west and in the Islands.

Dracophyllum is not very attractive. D. Urvillei has been occasionally seen, also D. longifolium. That very strange and striking tree, D. Traversii, was brought over by Major Dorrien Smith in 1908 ; it failed at Tresco—apparently the climate was too dry for it—but was successfully grown in a garden near Penzance to a height of at least twelve feet.

Ourisia, which is a small but very distinguished genus, is represented by O. macrocarpa and O. macrophylla, both of which have done well at Edinburgh and elsewhere. There are others which would seem to deserve attention here. O. caespitosa is at Kew.

New Zealand Orchids are naturally neglected. I have seen one species of Pterostylis (Banksii) only in this country. All, or nearly all, our Acaenas are commonly cultivated and well-known.

Carex is not a genus which gardeners care much about. The only New Zealand species which I saw at all often is C. Buchanani. I have also seen C. ternaria and C. secta (at Icomb Place only), C. comans, but no others of our fifty odd species. The only other Cyperaceous plant I saw was Uncinia compacta (Edinburgh).

Grasses, with a few exceptions, hardly come into the province of the gardener, and only a few of ours are to be seen here. I saw very fine and handsome specimens of Danthonia Cunninghamii at Tresco ; that very curious little grass, Ehrharta Thomsoni, in a greenhouse at Edinburgh ; a Fescue or two at Edinburgh ; Poa Mariototo, Arundo conspicua (Toi-toi), Poa Astoni, Agropyrum scabrum, and Dichelachne crinita (both sent to Edinburgh by Mr. Guthrie Smith).

Only a few of our Ferns are grown. Mr. Millard has a fine specimen of Blechnum pennamarina (but from Tasmania, I think). At Tresco there are all our Tree Ferns, and elsewhere in Cornwall Dicksonia antarctica and D. squarrosa do well. Schizaea fistulosa is grown (indoors) at Edinburgh ; Adiantum ethiopicum is at Ludgvan.

All our Conifers, or nearly all, are grown in the west, as at Tresco ; but at Kew they are all grown only in the Temperate House. Finally, I have seen no representatives at all of any of the following genera, in each of which some species might prove to have garden value ; Cladium, Luzula, the Orchids generally, Loranthus, Stellaria, Cardamine, Nasturtium, Notothlaspi, Drosera, Angelica, Caltha, Euphrasia, Forstera, Schizeilima, Pentachondra, Hectorella and Donatia.

Shingle Plants.

Not one of our true shingle plants is grown in Britain, and for that matter, I do not know that any of them have been grown with any real success in New Zealand. It is difficult to give these plants the peculiar conditions which they require—perhaps it is impossible—but there are several growers who are very anxious to try them. The Penwiper has been attempted and seeds have been germinated and seedlings grown for a short time by Mr. Millard, but they die off before reaching maturity, and this was my own experience with them in New Zealand. Perhaps, now that some of the gardeners know more of the actual conditions under which these plants grow, some success may be achieved, and they will certainly be given a chance. It would be a real triumph to grow and flower in England such a plant as Ranunculus Haastii, or R. chordorhizos, or Wahlenbergia cartilaginea. All these, I hope, will soon be tried here.

Work Yet to be Done.

It should be evident, even from this imperfect and rather lame account, that in spite of the assiduity and enthusiasm with which our plants have been hitherto cultivated in Britain, much yet remains to be done. Some of them no doubt, require such very special conditions (such as have been mentioned) that they may never be successfully naturalised here, but there are plenty of others which could certainly be grown and would as certainly be greatly welcomed and admired. One thinks, for instance, of Geum divergens, Gentiana corymbifera, Senecio Lyallii and S. scorzoneroides, Myosotis macrantha, M. explanata, M. concinna, Celmisia Hectori, Ranunculus Godleyanus, R. paucifolius, R. sericophyllus, R. pachyrhizos and R. Berggreni ; Helichrysum coralloides, H. grandiceps, H. pauciflorum, Epilobium brevipes, E. gracilipes, E. vernicosum—all these, and anyone will think of others—might well be grown in Britain, if not always as ornamental plants, then for their scientific value and interest.

I look forward to the chance of transmitting some of these at least to Britain in the near future, and doubtless there are many gardeners and field botanists in New Zealand who will gladly co-operate with me in this work—at any rate, I shall hope so—and if only a few of such efforts lead to success the labour of writing this account and collecting the materials for it will not, I think, have been entirely wasted.

---

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, Ante pp. 112-118.)

(*Continued from p.* 135.)

ENGLAND, N.E.

Yorkshire.—The winter which we passed through in this part of England was the most severe for many years. The whole of the month of February was practically a period of truly arctic conditions. Any unduly exposed top growths of small fruits, and even of the hardiest Apples, were killed. Loganberries suffered most, and are, consequently, a short crop. The Veitchberry, however, withstood the excessive cold splendidly and there was no dead wood on last year's canes at all. These canes have now produced lateral fruiting shoots eighteen inches long and a bumper crop is assured. Black Currants have the largest berries I have yet seen; there is no big bud or green fly. Fruits of every kind were a fortnight late in blossoming. The flowers were very profuse and of fine quality, but I noticed a shortage of bees at the critical time and so the set of fruits was small in proportion to blossom. *W. H. Bolton, 8, Ash Grove, Beverley Road, Hull.*

—— The fruit crops at Dalton are satisfactory, with the exception of Apples, Pears and Plums. These are disappointing, especially after the fine show of fruit buds in the early months of the year. The trouble commenced with the high temperatures experienced during the latter end of March and early April, which brought the buds on far too rapidly, and the succeeding night frosts took a heavy toll of the recently opened buds. Small fruits are again carrying good average crops, which would have been heavier still but for the drought, which has been severe in East Yorkshire. The rainfall measured in these gardens for the first six months of the year barely totalled seven inches. The soil here is a good medium loam resting on clay with a base of chalk. *James S. Coates, Dalton Hall Gardens, Beverley.*

—— The Apple crop is very light, chiefly on account of the lack of rain to give the fruits a start after setting. Strawberries suffered similarly. Gooseberries and Raspberries are good, but at the time of writing rain is needed to swell the latter. Black Currants are a good crop, but all fruits are suffering through lack of rain. *James E. Hathaway, Baldersby Park Gardens, Thirsk.*

—— The varying nature of the soil in this district has delayed the progress of fruit crops. Small fruits needing surface water have suffered most. Too late for the Strawberry crop, but helping on the Raspberry crop, the recent rain was very welcome. Apples should now commence to swell, but previously they looked like falling off, especially on soil of a shallow nature over rocky subsoil. In the valleys, where the subsoil is of clay, the trees have suffered very little. *J. G. Wilson, New Millerdam, Wakefield.*

ENGLAND, E.

Essex.—Apples and Plums are very scarce this season, but some varieties of Pears are fairly plentiful. Currants and Gooseberries are plentiful and good. Strawberries, but for the prolonged spell of dry weather, would have been abundant and good. The trees, generally, are making good growth and are free from insect pests. The soil here is a stiff clay. *Arthur Bullock, Copped Hall Gardens, Epping.*

—— Taking into consideration the prolonged drought, the fruit crops in these gardens are, on an average, good. Apples, during the flowering period and after setting of the fruits, appeared to be satisfactory, but during May the climatic conditions and severe attacks of insect pests caused many of the young fruits to fall. There have been abundant crops of Strawberries and Raspberries, the soil being suitable for these, but not for other fruits, as it is a light, black medium inclining to be gravelly, with clay and gravelly subsoil. *Thomas William Mead, Hylands Park Gardens, near Chelmsford.*

Huntingdonshire.—With the exception of Strawberry plants, which suffered severely during the winter, fruit plantations of all kinds wintered well, and blossomed profusely, owing, I think, to the well-ripened wood of last autumn. But the severe late frosts and subsequent dry season completely ruined the fruit prospects. The Apricot blossom was killed completely, and not a fruit is to be found on the trees. *Guy S. Aubertin, Conington Castle Gardens, Peterborough.*

Lincolnshire.—The fruit crops in this district, as a whole, are not satisfactory, no doubt owing to the severe late frosts and such a dry period as we have gone through recently; the total rainfall for the six months ending June, was 5·34 inches, as compared with 13·28 inches for the same period in 1928. *A. E. Jackson, Normanby Park Gardens, Scunthorpe.*

—— The poorness of the fruit crop is due to the frost experienced at blossoming time in many cases, and in others, where fruits had set, the harsh, dry weather caused them to dwindle and drop from the trees. *J. F. Vinden, Harlaxton Manor Gardens, Grantham.*

—— The fruit crops this year are, on the whole, very satisfactory. Considering the long spell of dry weather, Strawberries have produced good crops of grand quality. Gooseberries and Red and Black Currants are carrying heavy crops of excellent quality; Raspberries also promise well. At the time of writing Apples promise well, Plums are moderate, but Damsons are carrying heavy crops. The soil here is a good loam, with a marly subsoil. *A. Neal, Casewick Hall Gardens, Stamford.*

Norfolk.—All fruit trees and bushes here are carrying average crops. On July 4 we registered nearly three inches of rain, which was greatly needed, and fruits have greatly benefited by it. Temperatures have been variable. The soil here is very light and sandy. *Isaiah Johnson, Catton House Gardens, Norwich.*

—— The fruit crops generally withstood the drought remarkably well. Soft fruits are short, but the plants and bushes are growing well and are in excellent order. On the lighter lands, and particularly in the Norwich crag, the state of affairs is rather different and plants are somewhat dried up. Cooking Apples, generally, set well, and provided we get rain in sufficient quantity during the next two months there should be a good crop. It has been a good season for spraying and pests are well under control. *T. R. C. Blofield, Hoveton Fruit Farm, Wroxham.*

Suffolk.—It is difficult to estimate the quantity of fruits in this district, owing to the irregularity of the crops. For example, some varieties of Apples are carrying good crops, notably, Worcester Pearmain, Allington Pippin and Lane's Prince Albert, while Blenheim Pippin, Bramley's Seedling and Cox's Orange Pippin are failures. Plums are still more uncertain, trees in some positions having good crops, while others are barren. Among small fruits, Black Currants show the best crop. On the whole it is a disappointing fruit season due to late spring frosts of exceptional severity. *E. G. Creek, County Horticultural Institute, Abbey Ruins House, Bury St. Edmunds.*

—— Owing to the severe frosts of April and May, Apples and Plums suffered severely, and what fruits did swell suffered from the drought, which caused the Apples to drop badly. The rainfall here for the first six months of the year was 5·11 inches. *A. G. Marks, Clevering Park Gardens, Wickham Market, Woodbridge.*

ENGLAND—MIDLAND COUNTIES.

Bedfordshire.—The season, which promised so well, has not come up to expectations; after the hard winter we expected a congenial spring, but frosts occurred very late in the season and now, at the time of writing, drought is playing havoc with the fruit crops. Peaches and Nectarines are up to the average, but Apricots are again disappointing. Plums are an average crop, with Victoria, Kirke's and Monarch slightly over; Pears are about average, Doyenné du Comice being rather short. Apples are patchy, with Cox's Orange Pippin on the short side. Blenheim Pippin, Lane's Prince Albert, and earlier varieties have full crops, but the fruits are dropping badly owing to drought, with the result that no thinning will be needed. Strawberries are a very poor crop, for the winter played havoc with them and the drought set in when they started growing; the crop is the worst for years. Raspberries are a full crop and promise well. Black Currants, also, are very good, as are Red Currants. Gooseberries are a failure owing to the birds destroying the buds in the winter. Cherries are a poor crop, except Morellos, which are good. The season has been remarkable for the absence of aphis. The soil here is a sandy loam. *W. G. Warner, Chicksands Priory Gardens, Shefford.*

Buckinghamshire.—The remarkable recovery of all fruits from the severe winter is very outstanding. Bees were "friends in need" when stone fruits were in flower—a very fine set of Peaches and Apricots resulting. Plums did not flower well. Most Apple trees have set good crops and the fruits have developed well, in spite of a good crop last year. Pears flowered freely and, fortunately, a good percentage of the fruits have dropped, the good crop remaining being of clean and healthy fruits. Black and Red Currants are good, and Gooseberries and Strawberries are excellent, the size and flavour of the latter fruits being first-rate. Mulching did much to insure the success of the Strawberry crop. The soil in these gardens is sandy gravel, overlying chalk. *Geo. H. Emmett, Taplow Court Gardens, Taplow.*

—— The fruit crops, in general, are very good, which, I think, is owing to the season being so late that the blooms escaped the late frosts; small fruits are carrying heavy crops, but Apples, after a fine show of flowers, failed to set their fruits, owing, no doubt, to the dry weather experienced in May. One good point this season is the absence of Aphis, Black Currants being the only fruits attacked. The soil here is of a light nature, with a chalk subsoil. *W. A. Bright, Hughenden Manor Gardens, High Wycombe.*

—— There are good crops of most kinds of fruits in this neighbourhood, in spite of very bad weather during the whole of the flowering period, extremely cold N.E. winds, accompanied with severe frosts and snow showers, being prevalent throughout the spring. This only confirms the opinion of a good many observant gardeners, viz., that without the proper ripening or maturing of the fruit-bearing growths, a good crop of fruits cannot be expected. Severe attacks by caterpillars damaged Apples and Pears (especially the latter), but other kinds of fruit trees are fairly clean. The soil here is gravel, with a chalk subsoil, and dries up very quickly. *James Glasheen, Cliveden Gardens, Taplow.*

—— Fruits, in general, are of good quality and about average in quantity, being affected somewhat by the dry season. Strawberries suffered most from the late frosts, the majority of the first flowers being killed. The soil here is heavy clay. The trees are remarkably free from pests this year, more so than for a number of years past, and up to the present time spraying has not been necessary. *G. F. Johnson, Waddesdon Gardens, Aylesbury.*

—— The fruit crops here this year are well up to the average, except Plums, which are disappointing. The Plum trees flowered freely, but severe frosts during the flowering period completely destroyed the crop on all trees in the open. Trees on walls escaped somewhat, but the crop is a very light one. Apple and Pear crops are good, also Strawberries and all bush fruits. Peaches, Nectarines and Cherries are plentiful and well above the average. *F. Reid, Dropmore Gardens, Burnham.*

BUCKINGHAMSHIRE. — The fruit crops have suffered very much this season owing to late frosts, cold winds and the drought, especially standard trees. The rainfall for the first six months was 5·41 inches, which is far below the average for this district. *W. Turnham, Greenlands Gardens, Henley-on-Thames.*

CHESHIRE.—With the break in the prolonged spell of dry weather the fruit prospects have improved considerably. Culinary Apples are very promising, both as to quality and quantity. Gooseberries, Raspberries and Black Currants are very plentiful and the bushes are free from blight. Strawberries are improving, due to experimenting with some fourteen varieties and selecting the most prolific types. The Royal Sovereign strain shows no improvement in spite of new stock from certificated sources, and I have reluctantly resolved to discontinue its cultivation. The soil here varies from medium to heavy loam, the former resting on red sandstone, the latter on clay. The medium gives much the best results. *T. A. Summerfield, Alderley Park Gardens, Chelford.*

(*To be continued.*)

HOME CORRESPONDENCE.

[*The Editors do not hold themselves responsible for the opinions expressed by correspondents.*]

Rosa rugosa var. repens rosea. — Regarding the reference made to above Rose on page 27, I beg to state that this was raised in our nursery about 1904, as the result of crossing Rosa rugosa with R. gallica. It is quite different from R. rugosa var. repens alba in foliage and flowers, although it has the same prostrate habit. Both plants make beautiful and distinct specimens as standards, and as such they are grown here on Rosa polyantha stems, which impart a wonderful vigour to the plants. *G. N. Smith, Daisy Hill Nursery, Newry.*

Change of Work.—Not long ago the Industrial Fatigue Research Board reported that the cause of fatigue lay not only in the muscles but in the nerve centres concerned, and advocated short breaks in monotonous work for the recuperation of these centres. I was present once at a meeting of professional gardeners, and one of them remarked that gardeners were always tired, a statement which seemed to be supported by the experience of the others. Many will agree that gardening in general is more tiring than average manual work, probably because much of it has to be done in a crouching or stooping position. Let us combine one of the Committee's findings with our own experience and see if we can be helped in the result. Much of the fatigue of gardening seems to be due not only to the pressure on the organs of circulation, breathing, and digestion, due to the cramped position, but to the length of time in the same position while doing the same work. Much of this is often of a dull, monotonous character, *e.g.*, cutting grass edgings, weeding, thinning or pricking-out seedlings, and the like. Thus there are three factors in producing fatigue in the ordinary sense—lessened freedom of action for vital organs; long periods in one position, and the using up of the energy of certain nerve centres in consequence of the demand upon them being so prolonged. And over all is the influence of the mind upon the body generally, the boredom induced by the same dull routine adding to the weariness of the body. It often happens in modern scientific discoveries that old-fashioned sayings and practices are now given a *raison d'être*, and so the explanation of the old saying that a change of work is as good as play is obvious. This is not the sole concern of professional gardeners, for amateurs, especially those who are getting on in years, feel the need of husbanding their resources in the matter of energy. More work can be done in a day and the fatigue at the end of it lessened if the work is varied occasionally instead of being confined to the same job the whole day. If one is digging in the winter—very laborious work, if done really well—an hour's digging can be alternated with a half-hour's pruning on the adjacent bush fruit plantation, while mowing the grass can be changed with tidying up a flower border near by or tying in the climbers on the walls of the house. Out-of-door work arrangements, of course, are often at the mercy of the weather, and seasonal work, especially in the early spring, has to be hurried sometimes when a long-delayed opportunity comes, but those who are free to build their practice on the above principles will scarcely fail to find benefit in increased work with lessened fatigue and more pleasure in doing it. *A. Petts.*

Gardening Fallacies.—I have been much interested and amused reading what *W. Auton* wrote (p. 50) about "Gardening Fallacies. "Fifty years ago, at my school, we sowed Mustard and Cress on flannel on the very broad window sills, yet now I see it sown in soil, and splashed and mudded. As to watering: many amateurs seem to love dribbling water constantly on plants with roots nearly a foot deep, and ask what I do in a drought like this year. I answer "What the farmers and nurserymen with acres do." Many of us (amateurs) would like to know a little more about artificial manures for various plants at different stages of growth. I have gleaned much already from your columns, but whether any artificial will help seedlings of Tulips (species) or of Lilies or other bulbs to attain flowering size only one year sooner than some take, would be useful information. As to hardiness and frost: those are things which puzzle many. In my glass porch last winter 10° of frost and more on two nights did not injure Heliotropes or Pelargoniums; they were covered with newspaper and (what I am told saved them) the soil was nearly dust dry. Outside, in the corner of the porch (a due south corner), Eccremocarpus remained green, and buried under bits of Gorse, covered with canvas, I had Agapanthus, Lemon Verbena, Schizostylis, Zauschneria, Dieramas, and such like tender things, uninjured, while neighbours' thermometers were near zero. We should like to know much about the most efficient garden tools for the many different purposes, and the experiences of some of your correspondents; a light, but strong, and rustless spade would be very nice for old men. Years ago a light one was advertised, but the dimensions were excessive and so it was useless, except for giants. I am sorry to read that some think a gardener too old after forty. My parents had an excellent gardener, over sixty, who followed on with another member of my family, growing all the necessary vegetables until well over seventy, and a year ago his experience was a great help—and a surprise. As to women gardeners, although I state it, my daughter is unsurpassed; although having an indoor nursery and housework, her garden is a revelation, all the work of her own hands in regard to flowers and vegetables, and she sent a large surplus to the hospital close to where she lives, a few days ago. *Vere Caldwell, Chandler's Ford.*

FOREIGN CORRESPONDENCE.

THE AMERICAN METHOD OF ROOTING CUTTINGS.

IN practically all American gardens, both commercial and private, pure, sharp sand is the medium in which almost all cuttings are rooted. Compared with the use of sandy soil such as is used in Britain for most cool-house and bedding subjects, and Cocoanut fibre, which is much favoured as a medium for use in stove propagating cases, sand has many advantages. In the first place, it is sweet, clean to handle, and is not liable to be infected with injurious fungi. Secondly, it may easily be kept suitably moist without any danger of becoming waterlogged. It freely admits the passage of air, which is essential to encourage cuttings to callus and emit roots. The danger of damping-off is minimised and the same sand may be used time after time for successive batches of cuttings, thus eliminating the necessity of mixing up fresh quantities of material for each lot of cuttings.

The sand used is of the finest quality and is similar to that known in England as "Bedfordshire Silver." Beds from four to six inches in depth are made up on the greenhouse benches when a properly constructed propagating house is not available, or if, as frequently happens in the busy season, this latter is fully occupied. The sand is watered and rammed firm, and if the cuttings are fairly large, such as of Carnations, they are inserted in the ordinary way with a dibber, but small, soft cuttings of Ageratum, Lantanas and similar subjects, are inserted in a more speedy manner—a manner more in conformity with the popular conception of American "hustle." With the aid of a straight-edge, a straight slit an inch or two deep is cut with a piece of ordinary glass, or a knife, in the moist sand. The cuttings are then picked up one by one with the left hand, pushed into the open slit, and the sand is closed firmly about their bases with the fingers of the right hand. As soon as a row is finished the straight-edge is laid parallel with it, and a slit cut for the next row. The rapidity with which cuttings can be inserted by this means is surprising to the uninitiated, and the results obtained are excellent. So soon as all the cuttings are inserted they are well watered to settle the sand around them, lights are placed over them, and shade from bright sunshine is provided, and under this treatment they root very quickly. It is, of course, necessary to pot them into a more sustaining compost so soon as they are rooted.

It will probably surprise many English gardeners to learn that not only are Carnations, Lantanas, Cineraria maritima, Ageratum, Chrysanthemums, and such like propagated thus, but even Pelargoniums respond equally as well to this somewhat unusual treatment. The usual plan followed by British gardeners with these plants is to partially dry them, and then to insert them in pots or boxes of sandy soil and stand them in a frame or even in the open, in full sun, the idea being to avoid at all costs a moist atmosphere which might encourage damping-off. Yet here, they are dibbled in thickly, and covered with lights and shaded from the sun so that they are in a temperature of anything from 70° to 95°, and in an atmosphere saturated with moisture. Under this treatment a percentage of rooted cuttings as high as ninety-five or even more is obtained. I am strongly inclined to think that Pelargoniums would root equally as well in Britain if treated in like manner, and as rooting takes place very quickly, I believe that many growers could advantageously follow the Americans in this respect. *T. H. Everett, Pleasantville, New York.*

VEGETABLE GARDEN.

THE GOMBO.

THE Gombo is not a novelty, its uses as a vegetable having been described so long ago as 1854 by M. Léon Farrier, but it is not much grown in this country, although its cultivation seems to have expanded considerably in France in recent years, there being an increasing demand for it in the Paris "restaurants de luxe."

Gombo is the young and tender capsular seed-vessels of Hibiscus esculentus and is extensively used as a table vegetable throughout the British West Indies, South America and some parts of North America. The tender young pods are very mucilaginous, but make a palatable dish when cooked whole, or they may be cut into slices and used in soups and sauces, and served in these forms they are highly esteemed by the natives; they also enter largely into the composition of salads, in both the cooked and the raw state, and, in the latter particularly, they are considered to have valuable stomachic properties.

An annual plant, native of South America, its cultivation outside in this country is uncertain. In the South of France it succeeds out-of-doors, when raised inside and planted out and, under very favourable conditions, this might be possible in the south-west counties, but, like the Egg-plant, it requires the assistance of artificial heat to ensure safe cropping. *A. M. W.*

SOCIETIES.

NATIONAL CARNATION AND PICOTEE.

(Northern Section.)

The sixth Annual Exhibition was held in the Cutlers' Hall, Sheffield, on August 10; it was opened by Miss Maurice, Park Grange, Sheffield, who was presented with a shower bouquet of Carnations by Miss Jean Sectier. Councillor Gascoigne, of the Corporation Estates Committee, presided, and Alderman Wardley, when proposing the vote of thanks to the opener, declared, "People who do not love flowers, music and children, have no souls, are a source of danger, and you want to keep your eye on them, for they are not completely human." Dr. Guy H. Mead, President, said that the exhibition had a twofold object, to help the local blind, and to advance the progress of the National Carnation Society; they wanted amateurs to understand that the border Carnation was a hardier plant than the spring Cabbage. Carnations were not fastidious as to position or soil; many of the blooms exhibited, particularly in the amateurs' open border classes, were grown within one mile of the great city's steel works.

The show itself was held in conjunction with the Sheffield Gardeners' tribute to the Blind Flower Show, and as it proved a tremendous success, it is hoped that in a short while a considerable sum will be handed over for the use of the blind of the city.

Mr. J. Macfarlane, Airdrie, Scotland, was the most successful exhibitor, being awarded the Silver Cup for an amateur's display of border Carnations; in this display a bowl of Kelso was outstanding, and commanded the admiration of almost every visitor to the show; other varieties of merit were Florence Grisby, Mrs. Edmund Charrington, Sam Griffiths, Mrs. D. Thomas and Ebor. Mr. Macfarlane also took eight first prizes in the open classes.

Premiers were awarded to Mr. J. Macfarlane, for a yellow self Peter; a white ground Fancy, Steerforth; a Clove-scented variety, Steerforth; a yellow ground Fancy, Linkman; and a Fancy other than white or yellow, Sam Griffiths; Mr. S. Rabjohn showed the premier Picotee, Exquisite.

The Silver Cup presented by Mrs. G. H. Mead was awarded to Mr. Macfarlane, for Linkman; this bloom was stated to be the best Carnation ever exhibited at a Northern Section show, easily outclassing some excellent examples of Mrs. Edmund Charrington, this latter variety having obtained the award at all five previous shows.

In the amateur classes (Division I), Mr. Wilfred Secker (Secretary) secured the principal awards, winning the President's Challenge Cup and the Society's Silver Medal for the third year in succession, also winning a Silver Medal for the best bloom of Jean Secker in the show, first prize for the best vase of white ground Fancies, with a vase of Monica, Woodpark and Mrs. Edmund Charrington; and a special prize for the best bloom in this division with a fine specimen of Florence Grisby.

Mr. Secker led for three Selfs, dissimilar; Mr. W. H. Rhodes, for three Fancies; Mr. H. E. Pearson, for yellow-ground Fancies; Mr. W. Secker, for three white ground Fancies; Mr. W. Secker, for three Clove-scented Carnations; Mr. W. H. Rhodes, for three Picotees; Mr. W. Secker, for four vases of one variety; and Mr. W. Secker, for twelve blooms of Selfs and Fancies.

In Division II, Mr. S. Rabjohn was awarded the Society's Silver Medal for the highest points obtained, and received the first prize in each of the eight clases.

Mr. G. T. Evans, Mr. G. Camish, Mr. B. Marrison and Mr. G. H. Rotherham were also prize-winners.

The National Carnation Society's Certificate was awarded to Mr. Wilfred Secker for six blooms of Selfs and Fancies; Messrs. Clay and Sons' Special Prize was also awarded to Mr. Secker in this class.

Other special prizes presented by Messrs. Lowe and Gibson, Torrance and Hopkins, Mr. S. Pye and Mr. H. Swan, were awarded to Mr. S. Rabjohn, Mr. W. Secker, Mr. G. T. Evans, Mr. G. Camish and Mr. B. Marrison.

Mr. H. E. Pearson was awarded a Gold Medal, and Mr. S. Rabjohn a Silver Medal for displays of border Carnations.

First Class Certificates.

Miss Horn.—Rose-pink, Clove-scented; this received 97 points out of a possible 100, and is easily the best Clove-Self exhibited to date. Raised by Messrs. Torrance and Hopkins, Busby, Glasgow.

Mrs. G. Hill.—A white-ground Fancy, marked with rosy-scarlet. Raised by Mr. G. Hill.

Glenshee.—A white-ground Fancy, heavily marked crimson. Raised by Mr. J. Macfarlane, Airdrie, Scotland.

Awards of Merit.

Jean Secker.—A yellow-ground Fancy marked and edged with lavender and scarlet. Exhibited by Mr. Wilfrid Secker, Sheffield.

Ben Beswick.—A salmon-rose Self. Raised by Mr. G. Hill, Hillsbrough, Sheffield.

Glenfarg.—A buff-ground variety suffused with salmon-pink. Raised by Mr. J. Macfarlane.

BRITISH GLADIOLUS.

August 13.—The London Show of this special flower society, which was held in conjunction with the fortnightly meeting of the Royal Horticultural Society, in the New Horticultural Hall, Westminster, was not equal in size or the quality of the exhibits to the shows of the two previous years. It may be that the exhibiting members are reserving their chief energies for the show which is to be held at Southport next week. Considering how fully alive the present management of this recently-revived Society evidently is to the value of publicity in most directions, it was a little surprising to find that the educational possibilities of this show were rather neglected. It is to the exhibitors' cards that the average visitor looks for the information as to the objects of the various classes, but at this show the cards contained no clue to the object of the class beyond the group letter and the class number. This necessitated reference to a schedule, and schedules were not readily available. We suggest that the British Gladiolus Society might well follow the example of most of the older special flower societies and indicate the requirements of each class on the exhibitors' cards. Eight very fascinating novelties received Awards of Merit.

Awards of Merit.

Distinction.—A very fine, rich orange-coloured, large-flowered variety. This, and the two following, was shown by Messrs. R. H. Bath, Ltd.

Old Rose.—A very beautiful, medium-sized, large-flowered variety of rosy-salmon colouring, shaded with carmine and white in the tube.

Rival.—A medium-sized, large-flowered variety of good form. It has a large, rosy-carmine blotch on white ground.

Leen Wone.—A very showy, flaming orange-coloured Primulinus variety, probably the finest of its colour yet introduced. Shown by Major George Churcher.

Tapestry.—A splendid large-flowered variety. The pink ground colour is shaded with heliotrope and speckled with a darker shade of heliotrope. There is a reddish shading to the throat. Shown by Messrs. Kelway and Sons.

Jack Izod.—A large-flowered variety, probably best described as a crimson Purple Glory, but with larger flowers and of better form and substance. Shown by Messrs. W. J. Unwin, Ltd.

Scarlet Flame.—A Primulinus grandiflorus hybrid, and its name aptly describes the colouring of its shapely blooms. Shown by Mr. H. Prins.

Van.—A Primulinus grandiflorus variety, deep buff, with amaranth-purple lines on the lower petals of the wide open flowers. Shown by Mr. A. E. Amos.

Silver-Gilt Medals.

Mrs. M. Rumsey,—Deep ashes of Rose, flaked flame, lower petals blotched deep lake. A large flower of good substance and much rounder petals than usual. Shown by Messrs. W. J. Unwin, Ltd.

Pink Gem.—An outstanding Primulinus grandiflorus variety, with rose-pink, white-veined flowers, shaded with cream in the throat. Shown by Messrs. R. H. Bath, Ltd.

Silver Medals.

What Joy.—A large-flowered variety, the blooms being white, with canary-yellow blotches and deep purple pencillings in the throat. Shown by Messrs. W. J. Unwin, Ltd.

Geoffrey Henslow.—A Primulinus grandiflorus hybrid, deep coral-red, the white blotch being striped with the main colour and with faint primrose pencilling. Shown by Messrs. Kelway and Sons.

Bronze Medals.

Anne Croke.—A Laciniatus seedling, much larger than previous laciniated varieties. Shell-pink, darkening in flakes at the petal tips to rose, with slight pencillings in the throat. Shown by Major George Churcher.

Penelope.—Light magenta, the lobe petals having white blotches with deep purple pencillings. Shown by Messrs. Kelway and Sons.

Open Competitive Exhibits.

The best exhibits of eighteen Primulinus varieties, either introduced since 1926 or not yet in commerce, was staged by Messrs. R. H. Bath, Ltd., and included good spikes of Coral Queen, May Queen, Browse Delight and Spitfire. Major George Churcher, Lindfield, was second. In the class for twelve distinct spikes of "Florist and/or Commercial Varieties, Large-flowered and/or Primulinus (all sections)" the first prize was won by Messrs. W. J. Unwin, Ltd., who showed Thomas Edison and Purple Glory of considerable beauty. Major Churcher, who was second, included Dante and Laciniatus, an uncommon little fringed variety; Messrs. W. J. Unwin, Ltd., were also first in the class for three spikes each of large-flowered varieties, where they included splendid spikes of Bertie, Snow and Mount Everest. Mr. W. Yandell was second, and his best variety was Duchess of York.

There were seven colour classes for the large-flowered varieties, and in these the first prizes were awarded for the following:—Pink: Pink Perfection, shown by Messrs. W. J. Unwin, Ltd. Purple: Purple Glory, shown by Mr. H. Prins. Red: Red Emperor, shown by Messrs. W. J. Unwin, Ltd. Salmon: Prince of Wales, shown by Mr. W. Yandell. White: Mount Everest, shown by Messrs. W. J. Unwin, Ltd. Yellow: Golden Eagle, shown by Mr. H. Prins. Fancy: Hinemowa, shown by Mr. H. Prins.

Five spikes were required of each variety shown in the colour classes for Primulinus varieties, where the first prizes were awarded:—for Lavender: Taurus, shown by Mr. H. Prins. Pink: Shell Pink, shown by Messrs. W. J. Unwin, Ltd. Salmon: Salmon Beauty, shown by Messrs. W. J. Unwin, Ltd. White: White Butterfly, shown by Major George Churcher. Yellow: Souvenir, shown by Messrs. W. J. Unwin, Ltd.

Amateurs' Classes.

In group B, the first prize for three distinct varieties of the large-flowered Gladiolus, without blotch, was won by Mr. W. H. Pritchard, Chippenham, with good spikes of Flaming Sword, Phenomenon and Jacoba van Beierven. Mr. P. Bauchop, Alexandria, who showed Sultan, Margaren and Canicule, had the best three varieties, with blotch. Mr. L. C. Adkins, Chelmsford, showing Orange Queen, Alice Tiplady and Butter Boy, was first with three

Primulinus grandiflorus varieties. Mr. S. H. Gregg had the best six Primulinus varieties in two vases, and Mr. E. W. Hoyte was first with three varieties shown in one vase. Showing Sappho, Miss C. Anderson, Wantage, was first for a smoky variety. Prince of Wales, shown by Mr. H. Strutt, Colchester, was the best pink. Miss C. Anderson was first with Purple Glory. Mr. A. E. Amos was first with Red Emperor. Lutetica, shown by Mr. P. Bauchop, was the best white, and Schwaben, shown by Mr. E. W. Hoyte, was the best large-flowered yellow. In the colour classes for Primulinus varieties, Major G. Churcher, showing Dante, was first for a lavender; with Dew Drop, for a white, and with Ethylyn, for a yellow. Mr. R. B. Long, Maidstone, had, in Gelinotte, the best pink. Krelage's Favourite, shown by Mr. S. H. Gregg, Bowes Park, London, was the best red, and Orange Beauty, shown by Mr. E. W. Hoyte, was the best yellow.

In Group C., Mr. W. H. Pritchard, who included excellent spikes of Flaming Sword and Prince of Wales, was first with a very good exhibit of six large-flowered varieties. Mr. L. C. Adkins was first with good spikes of Sweet Lavender, Pride of Haarlem and Dr. van Fleet, in the class for three varieties. Mrs. Hennell, Ash Rectory, Kent, who included Chickabee, Maiden's Blush and Sheila of good quality, was first in the class for six Primulinus varieties. Mr. S. H. Gregg, Mr. R. B. Long, Mr. L. C. Adkins and Major George Churcher also won first prizes in this section.

In the Decorative classes, Mrs. W. Yandell, Maidenhead, had the best vase of large-flowered Gladioli. Messrs. W. J. Unwin, Ltd., were first with a good bowl of Primulinus varieties, and Mrs. W. Yandell was first with a tasteful exhibit in the well-contested class for three bowls of Primulinus varieties, and Miss Churcher was a good second.

The Piece of Plate offered in the special class for amateurs, was won by Mr. W. E. Phillips, Wood Green, with twelve handsome spikes representing the different sections.

SCOTTISH NATIONAL SWEET PEA, ROSE AND CARNATION SOCIETY.

(Provincial Show.)

August 15, 16 and 17.—The provincial show of this Society, which this year took place in conjunction with the show of the Royal Horticultural Society of Aberdeen, at Aberdeen, was a great success. The propaganda carried on by this branch of the parent Society in visiting year by year various centres is bearing good fruit, and all connected with the work deserve the heartiest congratulations. The exhibits were finely staged, the awards plainly and legibly set forth, for all of which thanks are due to Mr. John Smellie, Helensburgh, the enthusiastic and veteran grower, and the Secretary and Treasurer of the Society.

Sweet Peas.

The great tussle of the show was for the best twenty-four vases of Sweet Peas, and it proved a "bonnie fecht," but each and every one of the competitors came out of it with honour untarnished, and the feeling that they had put up a gallant effort. Annie, Lady Cowdray (gr. Mr. William Smith), Dunecht, Aberdeen, was awarded first place for a striking entry. There is little doubt Mr. Smith made a supreme effort. Included in his varieties were fine cleanly-grown specimens of Royal Mauve, Jessie, Jay Blue, Pinkie, Charming, Magnet, Charm, What Joy, Vectis, Purple Monarch, Montrose, Treasure, Hero, Colorado and Elizabeth. Mr. J. B. Campbell, of Newport, who was second, had little need to be ashamed of the fine work he accomplished, for he beat that renowned grower, Mr. John Grigor, Banff, who in turn beat Messrs. Torrance and Hopkins, Busby, an eminent Sweet Pea growing firm.

Mr. Grigor took leading honours for the best six vases of Sweet Peas, novelties of 1929. His winning entry included fine examples of Elizabeth, Orange Picture, Porcelain, Flamingo, Jaye and Vectis. There was a kind of see-saw result among the competitors for the honours in the single variety classes. Leading places were taken for cream, by Mr. James Macintosh, with Picture; crimson, Mr. Smith, Dunecht, with Honour; cerise, Mr. Grigor, with Glorious; white, Messrs. Torrance and Hopkins, with Model; orange-scarlet, Mrs. Lewis Harper, with Grenadier; lavender, Mr. Grigor, with Powerscourt; purple, Mr. Smith, with Purple Monarch; and mauve, Mr. Grigor, with Royal Mauve. For any other colour, one variety, Mr. Smith led the way with Colorado. He had also the honour of furnishing the best vase of Sweet Peas in the show, with beautiful samples of Lilac Queen, and he also provided the best vase of any 1928 or 1929 variety with a fine sample of Glorious. Altogether it was a red-letter day for Mr. Smith, and he received hearty congratulations.

Roses and Carnations.

Roses made a fine display, and those eminent growers, Messrs. Adam and Craigmile, Aberdeen, Messrs. D. and W. Croll, Dundee, and Mr. R. C. Ferguson, Dunfermline, had all a look in, but the great majority of the leading prizes went to Messrs. Adam and Craigmile, who annexed seven firsts.

In border Carnations, Messrs. Torrance and Hopkins practically swept the boards. The leading honours for perpetual-flowering Carnations went to the Dunecht Gardens for very fine examples.

Altogether, it was a delightful show, and gave unfeigned pleasure to all who had the good fortune to visit it.

KING'S WALDEN HORTICULTURAL.

This Society's show was held on August 7, and surpassed previous records in regard to entries and the number of visitors. Considering the serious effects of drought in Hertfordshire, the increase of entries by over two hundred is remarkable. In fact, the judges were surprised at the wealth of flowers and the quality of the vegetables.

Two interesting new features were the model miniature gardens (open class) and the essays on "My Garden" (by children).

In the open division, Mrs. H. E. Dunhill (gr. Mr. E. Howard), Harpenden, led for nine vases of Sweet Peas, and Captain Flower, Welwyn, was second. Among eleven entries for table decorations, the awards were made in favour of Mr. A. J. Pulham, Mrs. Creasy and Miss G. Wheeler, in the order named. For a collection of vegetables, Mr. T. C. Sell, Gaddesdon, won the premier award, closely followed by Captain Flower and Mr. E. Sutton.

In division B., which is confined to a radius of five miles, the leading competitors were Mr. W. Muddle, Mrs. Creasy and Mrs. Gunner.

In the local classes the principal prize-winners were Mr. H. Bodsworth, Mr. S. Todd, Mr. J. Wood, Mr. E. Field, Mr. E. Swain, Mr. W. J. Willcox and Mr. E. Sutton, all of whom were faced with keen competition.

The displays made by the trade were again of a high standard. Messrs. Wheeler, and Messrs. Harkness and Co. showed good stands of Roses. Messrs. R. and G. Cuthbert presented a large and brilliant display of Gladiolus primulinus. Messrs. W. Cutbush and Son also showed Gladioli in a large group of herbaceous flowers. Other exhibits were those from Mr. Clarence Elliott, rock garden; and Messrs. Cannon, artistic floral display.

Major J. F. Harrison (gr. Mr. A. J. Hartless), also put up large groups of vegetables and fruits. Messrs. Latchmore staged an interesting exhibit of coloured photographs of well-known gardens, and of flower groups.

The Secretaries—as in former years—responsible for the arrangements were Messrs. A. J. Hartless and W. G. P. Clark.

The Luton Red Cross Sports and the opening of the Bury Grounds added to the day's enjoyment.

Obituary.

Sir E. Ray Lankester.—By the passing of Sir Edwin Ray Lankester, zoology and biology, and to a lesser degree botany, have lost one of their oldest and most distinguished adherents. Sir E. Ray Lankester died at his house in Chelsea on August 15, at the advanced age of eighty-two, and his death will be lamented by a wide circle of friends and admirers. He commenced his education at St. Paul's School, went to Downing College, Cambridge, at the age of seventeen, but migrated to Oxford in his second year, where he graduated with first-class honours in natural science, and gained the Burdett-Coutts scholarship in geology and the Radcliffe Travelling Scholarship in 1870. He then went to Naples and worked at zoology and in 1872 was appointed Fellow of and Lecturer at Exeter College. He was welcomed to London on the occasion of his appointment as Professor of Zoology at University College, London, in 1874, by Huxley and many other leading scientists; in 1890 he was appointed Linacre Professor of Comparative Anatomy at Oxford, and in 1892 he was appointed Director of the British Museum (Natural History) and Keeper of Zoology, from which posts he retired, at the age of sixty, in 1907, in which year he was President of the British Association. He was a member of the Royal Society, and upon his retirement was created a K.C.B. He was a staunch follower of Darwin, and was also keenly interested in Mendel's experimental work in hybridising cultivated plants, while he was also a very prolific author, among his works, which remain as a memorial to him, being *Science from an Easy Chair*, published in 1910; *The Kingdom of Man* (1907), and *Great Things and Small*, published so recently as 1923.

William Latimer.—Mrs. Jervoise, of Herriard Park, Basingstoke, has suffered a great loss by the death of Mr. Latimer, her gardener, which took place on the 7th inst. He was with Mrs. Jervoise when she laid the foundation of her collection, which by his care and whole-hearted devotion he brought to a very high standard.

Mme. de Vilmorin.—We regret to learn of the recent death of Mme. de Vilmorin, widow of the late proprietor of the famous French nursery firm of Vilmorin-Andrieux et Cie. Mme. de Vilmorin, who was in her eighty-first year, died at Verrières-le-Buisson, the scene of her late husband's labours, in which for over fifty years she rendered him faithful and affectionate assistance.

ANSWER TO CORRESPONDENT.

Weeds on Canal Banks.—*C. A. F.* Poisonous or arsenical weed-killers distributed over the weeds, by a can with a rose on it, are the most powerful in destroying coarse weeds, but they would be dangerous to dogs and other animals as well as the fish in the canal. The arsenic could easily get washed into the water by heavy rain. We have seen this happen in a river, where waste lime with chemicals in it got dumped on the river bank. Many dead fishes were floating on the water lower down. Many firms have non-poisonous weed-killers that are harmless to domestic animals, etc., but their action might have an adverse effect on the fish, if washed into the canal, because fish pass so much water through their gills in breathing. It might be possible to dig up the larger tussocks of Rushes and cast them aside to dry, after which they could be burnt on a bonfire, which could be kindled by means of the cut weeds when they are dry. Another plan would be to cut over the Rushes close to the soil, after the young stems have grown nearly full size. This would weaken the Rushes considerably for the following year, when the cutting could be repeated. All the green portions of the stems should be cut, as then little or no food would be stored in the roots.

Hugo de Vries.

All botanists and students of genetics are glad that the Linnean Society this year presented the Linnean Medal to Professor Hugo de Vries in appreciation of the conspicuous value of his contributions to biology. It was nearly sixty years ago (in 1870) that de Vries published his first thesis on the influence of temperature on plants and since that now distant day he has pursued his botanical researches unremittingly and with great benefit to botanical science. The most remarkable of de Vries's earlier contributions to botany were concerned with osmotic pressure. Another great physiologist, Pfeffer, had shown that the sap enclosed in plant cells exercises a remarkably high pressure on the walls of each cell, and that owing to this pressure the soft walls of the cells are stretched almost to the limit of their elasticity, with the result that although a plant tissue, such as a leaf, may consist of 95 per cent. of water and other plant tissues of an even higher percentage, nevertheless the plant maintains its form, successfully opposes high pressures brought to bear upon it and may exhibit extraordinary feats of strength in the way of piercing and lifting stones. Hugo de Vries used the plant itself to confirm Pfeffer's discoveries. He measured the amount of pressure required to unstretch the plant—to plasmolyse it as botanists say. So soon as the water is withdrawn from the cell-sap the cell shrinks—as may be seen when a thin slice of plant tissue is examined under the microscope—and it is easy both by direct and indirect methods to ascertain what pressures must be exerted in a plant cell in order to make it begin to lose water and shrink. By such experiments it has been found that the pressures maintained in these minute fluid compartments, or vacuoles, which compose living plants are enormous. Thus, in the Beetroot, according to de Vries, osmotic pressure may be so great as twenty-one atmospheres (that is 640 lbs. to the square inch). This wonderful picture of plant cellular structures with which we are all now more or less familiar we owe mainly to the genius of de Vries. In his later period, still happily proceeding, de Vries turned his attention to plant breeding with no less important results than those which attended his earlier purely physiological researches. He discovered the fact that the characters which distinguish two varieties of plant, although they may seem to blend in the first generation of a cross between the varieties, may segregate in the second generation—a discovery which was the very keystone of Mendel's doctrine of heredity. Thus, although the credit for the all important discovery remains with Mendel, it is pleasant to remember that de Vries reached a similar conclusion, and independently. Since these discoveries de Vries has extended knowledge of genetics by a series of masterly investigations of the behaviour of Oenothera and other species and hybrids. Besides his own contributions to botanical science, de Vries has inspired many others, both by his pupils and by those whose perusal of his published works has imbued them with enthusiasm for research. Thus around the genus Oenothera a remarkable and vast literature has grown up; much of it, doubtless, of fleeting importance, but some of it of fundamental value to genetical science. Professor de Vries combines to an only too rare degree the powers of research and of exposition. It is a pleasure to learn from him no matter how intricate the subject may be on which he discourses. It is an impressive fact that one of the men who helped to lay the foundations of genetical science is still alive and leading the ever-growing army of researchers who are making such determined and successful attacks on the secrets of heredity.

Southport Show.—The sixth Annual Show held in Victoria Park, Southport, is rapidly reaching completion as these notes are written, for on the morrow (August 28) everything must be ready betimes as judging commences early and the Show Committee of the Southport Corporation is desirous of having every award card in position ere the public is admitted at 10.30 a.m. The majority of the fifty judges have already arrived and will meet the Mayor, Aldermen and Councillors at the Town Hall this evening. At least one set of judges will begin work shortly after 7 a.m. to-morrow and, with an interval for breakfast, will continue until their arduous task of making awards to the non-competitive exhibits is accomplished. This sixth show occupies an enormous space and is of special interest because it includes the exhibition of the British Gladiolus Society—which has fifty-five exhibitors and three-hundred-and-seventy-five separate entries; and the *Daily News* Sweet Pea Show—which numbers forty-seven exhibitors and six-hundred-and-fifty-eight entries. Taken as a whole, Southport Show has over five thousand entries (including several hundreds in the young folks' section for wild flowers and grasses), or about five-hundred more than in 1928. The huge display is housed in a large marquee which provides an area of 77,280 square feet, and five auxiliary marquees, with a total of 43,200 square feet. In addition, the Lancashire County Council Education Department fills a tent of about 800 square feet, while horticultural exhibits outside the tents and marquees occupy 28,000 square feet, and the horticultural sundries section occupies, approximately, 25,000 square feet of space—a grand total of 174,280 square feet. In all departments the sixth Southport Show promises to exceed in extent and quality all its predecessors. Leading nurserymen, seedsmen and private exhibitors have foregathered at this Lancastrian seaside garden city where Mr. Clark, the Parks Superintendent, has provided beautiful floral displays in the parks and along the front, while Alderman E. Wood, Councillor Crankshaw and the Show Committee, with Mr. T. E. Wolstenholme, the Secretary, have such a finely organised system of management that everything moves smoothly and everybody seems happy and busy. To-day, Tuesday, August 27, the weather is ideal, pleasant and not too warm, and if such climatic conditions continue there should be a record attendance and the exhibits will retain their beauty until the show closes at 9.30 p.m. on Friday, August 30.

Amorphophallus Titanum flowering at Kew.—Visitors to the Royal Botanic Gardens, Kew, during the last few days have had an opportunity of seeing a plant of the Giant Aroid, Amorphophallus Titanum, flowering in No. 10 house of the T range, which contains the large Lily tank wherein are the Victoria regia and several other tropical Water Lilies. Although it is not so large as the plant which flowered at Kew in 1926, it is, nevertheless, quite a good specimen, the height to the top of the spadix being about three-and-a-half feet; the tuber of this plant was received from a correspondent in Sumatra in May, 1927. The first specimen of Amorphophallus Titanum to bloom in Europe flowered at Kew in 1889, in which year it was described and illustrated in *The Gardeners' Chronicle*. The inflorescence on that occasion had a total height of six feet nine inches. In our issue of November 1, 1924, we published an extended account of this interesting Aroid, together with a series of illustrations showing the inflorescence at various stages of development, from Mr. P. Dakkus, Curator of the Botanic Gardens, Buitenzorg, Java. Other plants of interest in the Victoria regia house at the present time are Passiflora quadrangularis and Thunbergia grandiflora, which are flowering freely, and a large fruiting specimen of Typhonodorum Lindleyanum.

Bournemouth's Exhibition of Economic Plants.—Upon his retirement from Reading to Bournemouth, about three years ago, Dr. J. B. Hurry took with him his extensive collection of economic plants, and presented it to the Bournemouth Corporation. These plants, and others, have been taken great care of by the Corporation, and each summer a collection of them is exhibited in the Central Square Gardens, and proves a source of attraction to many visitors. Among the plants displayed this summer were Tea, Coffee, Cinnamon, Bananas—Musa Cavendishii and M. Basjoo; Hevea brasiliensis, Ficus elastica and F. Schlecteri (Rubber plants); Olives, Myrtle, the Loquat, the Pomegranate, Cocaine, Cocoa and Mango, together with fruiting specimens of Monstera deliciosa and the Guava.

Hop-picking in the Medway Valley.—Reports from the Medway Valley state that the Hop-picking season is in full swing and a record crop is anticipated. Special arrangements have been made this year for the comfort and health of the pickers, including special facilities of the treatment of "Hopper's rash" and "Hopper's eye," complaints which, although not dangerous, are painful, and result from picking Hops.

The London Daffodil Show, 1930.—The Royal Horticultural Society will hold its annual Daffodil Show on April 15 and 16, 1930, in the R.H.S. Hall, Greycoat Street, Westminster, and all entries for the competitive classes must reach the Secretary of the Society not later than by the first post on Saturday, April 12, but earlier if possible. Exhibitors wishing to stage non-competitive exhibits of Daffodils must send applications for space to reach the Secretary not later than by the first post on the Wednesday preceding the show. The staging of exhibits must be completed by 10.15 a.m. on April 15; judging will commence at 10.30 a.m., and the show will be open to the public from 1 p.m. to 7 p.m. On the second day, the show will open at 10 a.m. and close at 5 p.m. Copies of the Schedule, which embraces ninety-one classes, divided among eight sections, may be obtained on application to the Secretary of the Royal Horticultural Society, Vincent Square, London, S.W.1.

Playing Fields for Norwich Housing Estates.—Since the War, the Corporation of Norwich has erected over 3,000 houses, several estates having been developed, and in each of these, areas have been laid out as playing fields, bowling greens, etc., while, with a view to encouraging gardening, a garden competition, with substantial money prizes, is held annually.

Largest Cacao Trees in the World.—A very interesting account of "Historical Cacao in British Guiana" is given by Prof. J. Sydney Dash, Director of Agriculture, British Guiana, in *The Agricultural Journal of British Guiana* for June, 1929. Prof. Dash describes a visit he paid to Coomacka, where are the remains of a Cacao plantation that is referred to in *Timehri* (Vol. III, 1884), by the Hon. E. Howell Jones, as follows:—"One cannot leave this district without paying a visit to Coomacka, as I venture to think that here will be found some of the largest cocoa trees in the world; and my friend Mr. Nind, who accompanied me, is sure that there are none like them in Trinidad; not trees to suit a cocoa planter, but wild, luxuriant overgrown specimens, samples of what a cocoa tree if left to itself in suitable soil will grow to. Some of these trees, groups of gigantic stems, are from fifty to seventy feet high, with branches extending sixty-seven feet, and measuring at a distance of five feet from the ground, nine feet five inches in circumference. One single stem which we carefully measured had a circumference of three feet four inches. Few pods grow on these trees, but what there is of them are large, of the yellow variety, containing an average of forty beans." In 1913 the late Sir John Harrison visited this site and in an official report adds the following comment to the description given above:—"Now many of these past giant cacaos have fallen, but along each fallen trunk new trees, many of them thirty to forty inches in circumference have sprung. The cacao appears to me after very careful examination to be all of one type and to be quite pure in type. It is the strain or type formerly known as Golden Caracas, probably the best cacao in the world. The pods are green in the earlier stages, passing through light yellow, and yellow to a full glistering golden-yellow when mature. The husks are thin and the beans full, round and of excellent quality. There is not a speck of colour other than golden-yellow on the fruit as pendent from the trees. It is now an exceedingly rare occurrence to find cacao which is absolutely pure bred of any desired type. Here we appear to have a supply of pure bred cacao of one of the most desirable types. I think we ought to take steps to utilise it." Harrison also drew attention to the fact that a similar Cacao is described by Schomburgk, whom he quotes:—"Near the Quitaro river we had to cross numerous swamps abounding in a species of cacao (*Theobroma bicolor*[*]). The large melon-shaped fruits of all sizes, some green, some of bright yellow, were eagerly collected by the Indians, who, however, did not appear acquainted with the fine aroma which the seed itself possesses. We collected a number of seeds of which I counted as many as sixty in one capsule. They afforded us for some mornings the most delicious cup of cocoa I ever tasted. It is remarkable that cocoa in its wild state is only found in swampy, or at the best, moist situations. The trees which I observed, although of a peculiar growth, almost shrubby, and the trunks less developed than in large forest trees, often attain the height of fifty feet. The capsules were large and contained from sixty to seventy seeds, which were larger than in the cultivated kind but not so thick." Prof. Dash's observations confirm, in a general way, the description given of the trees growing in an abandoned state at Coomacka and he states that in spite of the disease and dense undergrowth one cannot but be impressed by the remarkable growth of the trees, of which, according to a report made in 1917, there were two hundred in an area of one-and-three-quarters acre.

Dr. F. V. Darbishire.—Dr. Francis V. Darbishire, who has charge of the Chemistry section of the work at the Royal Horticultural Society's Laboratory, Wisley, was born at Dwygyfylchi, near Penmaenmawr, North Wales, on August 1, 1868, and is the second surviving son of the late Vernon Darbishire, Esq., J.P. After attending a private school at Manchester, he finished his education at a school at Dresden, in Saxony. He took an honours degree in chemistry and his B.A. at Oxford as a member of Balliol College, and his Ph.D. degree, also in chemistry, at Leipzig University. He was then consecutively Assistant Lecturer and Demonstrator at Cardiff, Manchester University and Wye College, Kent. After studying the Beet Sugar business on the Continent he was appointed chemist to a Beet Sugar factory in North Germany, from where he was sent as a civilian prisoner to Ruhleben during the War, and remained there for over three years. Shortly after his release, early in 1918, he came to the Royal Horticultural Society, at Wisley, in August, and since 1920 he has continued, as his successor, the work of Mr. H. J. Page when he removed to Rothamsted; this work includes the analysis of samples for the Fellows of the R.H.S. Dr. Darbishire has published several books, reports and papers. Among the latter is one on oxidation, published at Wye College; it contains the earliest suggestion for partial sterilisation of soils by means of heat and weak antiseptics.

DR. F. V. DARBISHIRE.

Walnut Competition.—In instituting a Walnut competition—which is to take place at Vincent Square on November 9—the Royal Horticultural Society is doing work of considerable national, as well as horticultural, interest, and should, therefore, receive all possible help from the Fellows and others who can afford it. Gardeners readily understand that as the majority of Walnut trees in this country are seedlings, they vary considerably, for each seedling is a distinct variety. The Nuts borne by many compare unfavourably with imported Nuts and as a result, the bulk of the Nuts consumed in this country are brought from abroad. This state of affairs is likely to continue until such time as good varieties adapted to our climate are found, propagated by grafting, and grown commercially on an extensive scale. The object of the competition is to discover good varieties. And when they are found it is proposed that shoots from which scions can be made should be sent to the East Malling Research Station, East Malling, Kent, and there grafted for distribution. Therefore, one of the conditions of the competition is, that successful competitors shall (if desired) supply twelve shoots from each prize-winning tree from which scions for grafting can be made. Each competitor who sends scions will, in due course, receive two of the young trees obtained from his scions, and the remainder of the young trees, if they prove satisfactory, will be used for the further propagation of the variety. The scheme has the cordial approval of the Ministry of Agriculture, which has provided part of the money for the prizes, and Mr. Howard Spence, a recognised authority upon Walnuts, has very kindly undertaken to carry out the preliminary examination of the Nuts sent for competition, and to assist in the final judging. Anyone who has one or more Walnut trees may have a variety worthy of extended cultivation, and, therefore, all who grow Walnuts, whether they are Fellows of the Society or not, are invited to compete and thus assist the Society in its search for varieties of outstanding merit that will prove economically valuable. Full particulars of the competition—for 3 lbs. of fresh and 3 lbs. of dried Nuts, respectively—may be obtained from the Secretary, R.H.S., Vincent Square, Westminster, S.W. 1. The Schedule contains the scales of points that will be used for judging each class.

Young Gardeners in Leipzig.—On August 17 and 18 a re-union took place at Leipzig of members of the German "Young Gardeners' Association." This is the first occasion on which a combined meeting has been held of young gardeners drawn from all parts of Germany, but doubtless it will now become, if found practicable, an annual fixture.

Belgian Florists' Annual Excursion.—On August 4, the Belgian Florists' Association held its annual excursion, which consisted of a long drive through some of the most beautiful scenery of the Belgian Ardennes, finishing with luncheon at La Concession, the country mansion of M. Odon Warland, Hon. President of the Association and well known as the proprietor of the cigarette works near Brussels where the enormously-popular "Boule Nationale" cigarettes are manufactured by the million. The excursionists, eighty-nine in number, left Brussels at 7 a.m., and arrived at La Concession at 2.30 p.m., an hour-and-a-half after the appointed time, but they were none the less warmly welcomed by M. and Mme. Warland, and the luncheon was thoroughly appreciated by the guests. After coffee and liqueurs on the terrace, the guests visited the model farm attached to the château, and the beautifully-tended gardens, after which they returned thanks to their host and hostess and embarked in a fleet of motor-cars for the homeward journey.

Parks and Botanic Gardens Superintendents' Association.—The members of the London and District Branch of this Association will visit Messrs. Sutton's trial grounds and seed establishment at Reading, on Tuesday, September 10. The party will leave by motor-coach, starting from the Elephant and Castle Station (Southern Railway) at 9 a.m. Park Superintendents and their assistants who would like to go should communicate with the Secretary of the London Branch without delay.

The Comte de Kerchove.—We learn from the Belgian press that the Comte de Kerchove de Denterghem, who has been elected a member of the Belgian Senate, has resigned his position as Governor of East Flanders. Those of our readers who attend the Quinquennial Shows in Ghent will be familiar with the tall, commanding figure of the Comte, who has always taken a leading part in the exhibitions, and in Belgian horticultural affairs generally. As a member of the Chambre, he has always been zealous to defend the interests of horticulture whenever they have appeared to be threatened, and no doubt, as a Senator, his good offices will be continued. An appreciation of the Comte de Kerchove, together with his portrait, appeared in our issue for March 3, 1928, p. 148.

---

[*] His use of "bicolor" is open to question, the term being applied to a distinct species of no economic value.

Rose Show in Koburg.—On July 27, an interesting exhibition of cut Roses was held at Koburg, Germany, organised by the local horticultural society. In spite of the extreme dryness of the weather preceding the show, excellent displays were made, particularly by W. Kordes Söhne, Sparrieshoop; G. Wöhner, Koburg; C. Gramm, Weimar; M. Krause, Alveslohe; H. Lindecke, Remagen; Viktor Teschendorff, Cossebaude; and M. Leenders and Co., Steyl, Holland. It was remarkable that most of the newer varieties shown were either yellow, flesh-coloured, or of similar tones; good, new, dark-red Roses were—as they usually seem to be—of rare occurrence, although Portadown (raised in 1928 by Messrs. S. McGredy and Son) was of a good, clean, deep red colour. Marquise d'Andigné (Leenders, 1927), scarlet-carmine-red, and Souvenir d'Alexandre Bernaix (P. Bernaix, 1926) were also good dark reds. Two unnamed red novelties shown by W. Kordes Söhne, seemed good, but judgment must be reserved until their behaviour in the open can be observed. Frau Dr. Rebhuhn, raised by the same firm, attracted much attention; it resembled Gruss au Koburg in colour, orange-reddish-brown shading to deep golden-yellow, and is apparently of strong growth; the form of the flowers was good and the stems firm. The new Pernetiana Rose, Julien Potin (J. Pernet-Ducher, 1927) was shown by the firm of Kölle, Heilbronn; it resembles Souvenir de Claudius Pernet in colour, but has an advantage over that variety, as it has not the tendency in bad weather to fail to open. Another Pernetiana novelty was Ville de Paris (J. Pernet-Ducher, 1927). Probably the Rose most seen was the favourite Mevr. G. A. van Rossem, a fine, strong, golden-yellow variety.

Royal Caledonian Horticultural Society's Autumn Show.—The annual Autumn Show of this Society will be held on September 11 and 12, in the Waverley Market, Edinburgh, and will be opened by the Countess of Haddington. In addition to the usual cash prizes, which have been increased considerably this year, and trophies, there is the John Phillips Memorial Challenge Trophy, valued at sixty guineas, presented by Mrs. Phillips, of Edinburgh, in memory of her husband, who died in 1917, while President of the Scottish Horticultural Association, which is now incorporated with this Society. The trophy is for six bowls of Roses, not more than twelve blooms in each bowl and not less than six varieties, the bowls and displayers to be supplied by the Society. Another additional trophy is the Thomson Challenge Trophy, for Grapes. A special feature of this show is the Abol Challenge Trophy competition; this trophy is offered for the exhibit which demonstrates the greatest advancement since the war in any one family or kind of flower, fruit, vegetable, tree, shrub or foliage plant. From the number of entries already received it is assured that the show this year will be a record one. Prize schedules may be obtained from the Secretary of the Society, 4A, St. Andrew Square, Edinburgh.

"The Gardeners' Chronicle" Medals.—*The Gardeners' Chronicle* Silver-gilt Medal, for the best display of rare plants or flowers staged at the Royal Horticultural and Arboricultural Society of Ireland's Summer Show, on August 7, 8 and 9, was awarded to Captain Lewis Ryall (gr. Mr. T. Webster), Old Conra Hill, Bray, Co. Wicklow. The Silver-gilt Medal presented by *The Gardeners' Chronicle* for competition at the recent Shrewsbury Floral Fête, was awarded to the Rt. Hon. Lord Swaythling (gr. Mr. F. J. Rose), Townhill Park, Bittern, near Southampton.

Gift to Waite Agricultural Research Institute, South Australia.—Munificent bequests by public-spirited citizens have enabled South Australia to prosecute scientific research investigations into primary industries on a scale befitting the importance of such work in a State which is mainly dependent on its rural production for its prosperity. A generous legacy left by the late Mr. Peter Waite led to the establishment, in 1925, of the Waite Agricultural Research Institute, where much valuable scientific inquiry has been undertaken. A subsequent gift of £10,000 by Sir John Melrose, has assisted in the erection of a chemical laboratory in which research work is being carried on in conjunction with the Waite Institute. Recently the Commonwealth Council of Industrial Research proposed to make the Waite Institute the Commonwealth's centre for soil research, and suggested that if capital was forthcoming to build the necessary laboratories the council would provide the equipment and be responsible for the cost of staff and maintenance. Mr. Harold Darling, head of the milling firm of Messrs. John Darling and Son, has, on behalf of himself, brothers and sisters, contributed £10,000. The Darling family previously gave £15,000 to the Adelaide University for medical laboratories in honour of their father.

Mr. A. E. Tylecote.—We learn that Mr. A. E. Tylecote, one of the founders of the Guildford and District Gardeners' Association, will leave England on September 3 for a six months' holiday in Australia. Mr. A. E. Tylecote (gr. Mr. Long) was awarded *The Gardeners' Chronicle* Silver-gilt Medal at the recent show of the above Association for a grand collection of Sweet Peas.

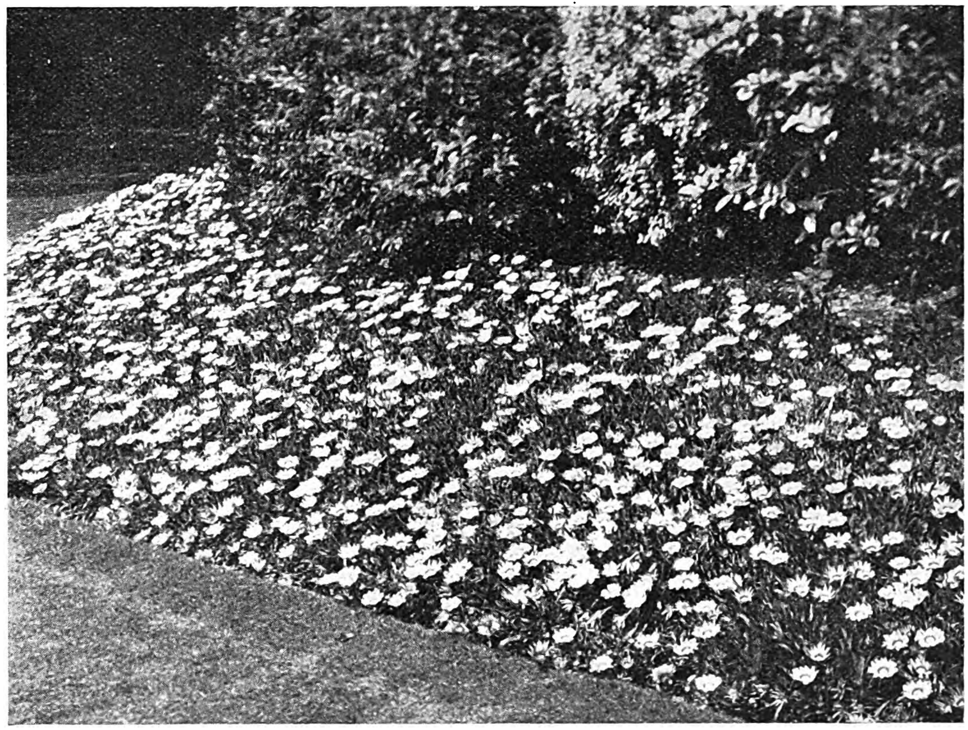

FIG. 79.—GAZANIAS IN ST. JAMES'S PARK, LONDON.

(see p. 163).

Appointments for the Ensuing Week.—TUESDAY, September 3: Salford Flower Show (three days); Royal Caledonian Horticultural Society's meeting. WEDNESDAY, SEPTEMBER 4: Royal West Renfrewshire Horticultural Society's Exhibition (two days); National Carnation and Picotee Society's meeting; Rotherham and District Horticultural and Chrysanthemum Society's meeting; Gainsborough Allotment-holders' Association's meeting. THURSDAY, SEPTEMBER 5: Newtownards Horticultural Society's Exhibition; Bideford and District Horticultural Society's meeting; Abergavenny Horticultural Association's Annual Exhibition; North-east Coast Flower Show (three days). FRIDAY, SEPTEMBER 6: London Allotments and Garden Society's Exhibition (two days). SATURDAY, SEPTEMBER 7: Alnwick Horticultural and Industrial Society's Exhibition; Leeds Paxton Society's Dahlia Show.

"Gardener's Chronicle" Seventy-five Years Ago.—*The Curl in Peach Trees.*—The aphis may easily be got under by the use of Tobacco-water, and attention. The Tobacco-water may be obtained from a manufactory if you should live near one! but I find it quite as economical to buy the Tobacco and make the water myself, as I am obliged to pay nearly as much for jar, carriage, and porterage as the water costs. I get a pound of the best shag Tobacco, which costs 3s. 6d., and a pound of soda, which costs 1½d., and dissolve the soda in two gallons of boiling water; it is then poured on the Tobacco, stirred, and allowed to remain a few minutes; the liquor is then strained, and two gallons more of boiling water added; this is again strained, and made up to about eight gallons by the addition of cold water, and put on the trees at 100° of heat, on a still, moist evening (if one can be found at that time of year). This is applied with a fine syringe, and the quantity is sufficient for twelve trees, each occupying 140 feet of wall. If you have shading materials at hand, the trees may be shaded, in case the sun breaks out strongly. The mixture may be left on till the next evening, when the engine should be used pretty freely, in order to wash off not only the mixture, but also the dead and dying insects, and as many as possible of those that the mixture does not kill, which, if properly applied will be few. But if shading be inconvenient, the engine and clean water must be used in the morning following the application of the Tobacco and soda, or the sun, being assisted by the crystals of the soda, may scorch the young leaves. The engine and clean water should be used frequently, to dislodge any insects that may be again establishing a colony on any part of the tree. It has been computed by, I think, Bonnet, that an aphis will multiply itself in one season 8,000,000 times, if left undisturbed in a favourable situation; and of all places, I know of none more favourable to them in the early part of the season, than the Peach tree; hence the necessity of observing the old proverb, that "a stitch in time saves nine." The trees will rarely want more than one dressing of Tobacco, if well attended to with clean water after the first application—or, at the outside, two dressings of Tobacco will suffice for one season.—*Cox on the Peach and Nectarine.*—*Gard. Chron., September* 2, 1854.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Duckyls Park, East Grinstead, Sussex.

Coelogynes.—Plants of the beautifully-coloured C. pandurata, also the hybrid C. burfordense, that have just passed out of flower, will require some attention at the roots, as new roots will be observed to be pushing from the partly developed growths. Being of a rather rambling habit, the plants are best accommodated in long, teakwood baskets. Some of the old back pseudo-bulbs should be removed to keep the plants in a limited place, while coarse Osmunda fibre and Sphagnum-moss form a suitable rooting medium, inserting lumps of charcoal as the repotting proceeds to keep the compost porous. The plants will thrive well if grown in a moist and shady position in the warm house, where the surroundings and baskets may be syringed occasionally. Water should be afforded sparingly at the roots until they are well established, when the supply should be increased each time the compost approaches dryness. As the season advances, more light should be allowed to reach the plants, although shade should be afforded from strong, direct sunshine during the winter months. C. pandurata requires very little water at the roots to keep it in a normal condition; if too much water is afforded to these Coelogynes during the resting period, decayed roots and unsightly spotting of the foliage will result, and often the loss of the plants. Plants of Coelogyne cristata are growing rapidly and established specimens will require ample supplies of water each time the compost approaches dryness. An occasional application of weak liquid manure is beneficial at this stage until the pseudo-bulbs are developed, when more light and air will be required to assist the ripening of them. Those plants that were repotted late in the season and are not yet established in the new compost should be watered very sparingly, only clear water being used. Shade them from direct sunshine, and the surroundings should be kept moist by damping between the pots; an occasional spraying overhead on fine days is beneficial.

Shading.—The season has now arrived when most of the Orchids will require more sunlight and air to help the growths to mature well in order to withstand the winter without damage, and also to ensure the production of good flowers. As the sun declines in power the blinds should be lowered later and removed earlier in the afternoon; allow the plants to receive so much light as possible without injury to the foliage. Permanent shading that has been used on the glass in conjunction with the blinds should now be removed, as the blinds themselves will provide sufficient shade.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Early Dessert Apples.—There can be no doubt that Apple Irish Peach, when well grown, is the best first-early dessert Apple we have, but its culture, and the pruning in particular, is not perfectly understood by all who possess this excellent variety. It is essentially a "tip-bearing" variety, and for that reason the winter pruning differs from that of most other varieties. In fact, there should be very little, if any, winter pruning, any pruning required being put off until mid-June, or until the trees have cast all imperfectly fertilised fruits; then, any twigs not carrying fruits may be cut back as desired, and so maintain vigour and form in the trees. The next Apple, in order of maturity, is Beauty of Bath, and this should be grown by all who appreciate an early Apple. The fruits from both these varieties should be eaten direct from the trees, otherwise, if they are kept for any length of time, the flavour will be lost. The variety Lady Sudeley comes next, especially the scarlet-fruited sort, which is of very handsome appearance, and of fairly good flavour. This fruit is best eaten fresh from the trees, but will keep for a month in the fruit-room without loss of flavour. We have some bushes of Langley Pippin here, which were budded on Paradise type VI, in 1923, and are now bearing a fair crop of very handsome, highly-coloured fruits. This variety is the result of a cross between Gladstone and Cox's Orange Pippin, both remarkable for high flavour, which is passed on to the offspring. Another highly-flavoured Apple is Ellison's Orange. It is sometimes described as an early Cox's Orange Pippin, which is one of the parents, and which it resembles in shape and colour; the season is October and November. There are few varieties of Apples that bear so consistently as James Grieve. Year after year, it never fails to bear a crop of handsome fruits, which are lemon-yellow in colour, striped with red. The flesh is tender, very juicy, and of good flavour. It should be in every collection on account of its reliability, and is in season during September and October. Another variety which bears with remarkable regularity is Worcester Pearmain. The colour of the fruits is a brilliant scarlet to crimson, consequently it is one of the most popular market Apples in its season. The flesh is crisp, although rather tough, but sweetly-flavoured. It is at its best during September and October.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

Early Peaches.—As the trees in early and succession houses are cleared of fruits, prompt attention to pruning, cleansing and the rearrangement of the shoots will be necessary. As a general rule, all superfluous growths which have borne fruits should be removed, as they interfere with the ingress of light, and now is the best time to cut them away. When this has been done it will give a good deal more room and will enable the operator to cover all the bare stems with young shoots and foliage, the best of all shields against the hot sun. If the wood is fairly strong and the foliage good, little or no stimulants will be needed; on the other hand, trees which from age or heavy cropping show signs of weakness, may be stimulated by liquid manure and light dressings of artificial fertilisers in preference to organic manure. If lifting or root-pruning of trees in early houses is contemplated, now is the time to make active preparations for carrying out the work. Fairly heavy loam should be secured in readiness and corrected by the addition of burnt clay and lime-rubble, with a sprinkling of bone-meal, according to the quality of the compost. Good drainage is the first and most important step in the formation of all fruit tree borders, and the space left for the reception of the compost may range from twenty inches deep, if the staple soil is heavy, to thirty inches where it is light. Successional trees cleared of fruits in the early part of August will have ample time for ripening their wood, and should have plenty of air by day and night. They should be kept thoroughly moist at the roots, and constant attention should be given to removing all surplus wood so soon as the trees are cleared of their fruits. Gather the fruits early in the day when dry and cool, and for home use about twenty-four hours before they are wanted.

Late Peach Houses.—Trees whose fruits are swelling very fast should be well syringed early on fine mornings, and again after the ventilators are closed. Pure soft water equal to the mean temperature of the house should always be used. If fly is troublesome, night air, after light fumigation may be omitted, but the trees should be well syringed before the sun strikes the house the following morning. As the fruits show signs of ripening, heavy syringing and night damping should be reduced, but by no means discontinued, and more air may be admitted, if possible. These trees should be kept exceptionally thin, no shoots being retained which will not be wanted next season. Root lifting in these houses, be the roots inside or out, should always be performed before the trees show signs of becoming gross in growth.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Winter-flowering Begonias.—These are now in various stages of growth and while some are becoming well-established in their flowering pots, others will require attention with regard to further potting, but there is one great advantage attaching to these useful plants and it is that they may be flowered well in sixty-sized pots or up to a twenty-four, by judicious feeding. Fumigate the plants frequently to keep mite in check, as no plant will thrive if this pest is present.

Repotting old Cyclamens.—Where these have been saved for growing on another season they should now receive attention with regard to being placed in their flowering pots. In these gardens we select a few of the best colours for growing on the second season; these give a succession of flowers to those that are raised from seeds, and in most cases a wealth of bloom is secured. After potting, place them in a cold frame which should be shaded and kept rather close for a short time to encourage root action. Water them sparingly for several weeks, but the plants may be sprayed frequently to encourage growth. Cyclamens are subject to attacks by aphis, mite and red spider; the first two may be kept in check by light fumigations with XL All compound, while the latter may be kept at bay with Volck, used strictly according to directions.

Souvenir de la Malmaison Carnations.—These delightfully-scented Carnations are not grown nearly so much in these times as in the past, partly owing to the popularity of the perpetual-flowering kinds. They undoubtedly make a welcome change to these latter sorts and can be timed to fill in the gap between the first and second crop of flowers of the same. Where they were propagated by layering during July they will soon be ready for lifting and potting, but several days before proceeding with this work, the layers should be severed from the old stock and the soil well watered, so that they can be lifted with all their roots attached. Those that have rooted freely may be placed in three or four-inch pots, while those that have made less roots should be potted in sixties. The potting compost may consist of good, open loam, with plenty of old mortar-rubble and coarse sand added, and it should be moderately dry to allow it to be made fairly firm by ramming. After potting, stand the plants in a cold frame, which should be kept close for a few days and shaded from bright sunshine. When it is found the plants have established themselves in the new soil, admit air freely and grow the plants under the coolest conditions possible.

Pelargoniums.—Varieties of the Show and Regal Pelargoniums that have been kept out-of-doors should now be cut hard back and laid on their sides for a week or so to ensure a complete rest before repotting them into smaller receptacles. It is always advisable to root a few cuttings of these each year to keep up a vigorous stock, and the best shoots should be selected for this purpose. These will soon form roots if stood in a cold frame and protected from heavy rains. The required number of old plants should be repotted into smaller receptacles so soon as they show signs of breaking into new growth; they should then be stood in a cool house, in a light position close to the roof-glass, and allowed plenty of fresh air. Cuttings should be potted singly into small pots when well rooted, and treated in the same manner as the old plants.

Caladiums.—As these finish their growth they should be gradually dried off, but in doing so it is not wise to subject them to low temperatures.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Turnips.—Encourage the recently sown plants to make quick growth. Thin the seedlings early and stir the soil frequently about them with the Dutch hoe. Should the Turnip fly be troublesome, dust the plants with soot or fine wood-ashes.

Leeks.—Fill any vacant ground with this vegetable, for although the season is getting late for planting, Leeks make rapid growth in autumn and come in for spring use, when other vegetables are scarce. Early plants may have assistance with applications of liquid manure. The tips of the maincrop plants should be cut off and soil drawn up around the necks of the plants to assure a good length of blanched stem.

Lettuces.—Prick out further batches of Lettuces in sheltered corners, using hardy varieties which will withstand the winter.

Spinach.—More Prickly Spinach may be sown to provide plants for spring use. When large enough, thin the seedlings to a reasonable distance apart. A dressing of soot between the lines will assure well coloured foliage.

Potatos.—Second-early varieties may now be lifted and placed in store, thus clearing the ground for spring Cabbages. Manure the ground and dig it well, and after digging, give a dressing of slaked lime, working it well into the ground with a fork before planting the Cabbage crop.

Seakale Beet.—Where this crop was sown late, the seedlings should be thinned to a suitable distance apart. The thinnings may be transplanted.

Beetroot.—Early Beetroots should be lifted and stored in ashes in a cool place, for if left in the ground they become too large for use.

Carrots.—Early Carrots may be lifted and stored in sand, for if left long in the ground and heavy rain occurs they will split and will not keep any length of time in store. Lift this crop when the weather is dry.

Chicory.—The Chicory plants will now be growing fast, and later-sown plants which have not yet been thinned should receive attention in this respect at once; allow plenty of room between them to encourage the formation of large crowns for forcing.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Hardy Perennials.—Border plants raised from seeds should be planted out in their flowering quarters so that they may have time to establish themselves before the winter. Such subjects as Aquilegias, Delphiniums, Pyrethrums and Primulas of all kinds should be so treated except in the most uncongenial circumstances, when it may be advisable to defer the planting until March.

Chrysanthemums.—Early-flowering Chrysanthemums in pots should be housed when the flowers show colour, as rain soon does irreparable damage. After removing any unsightly leaves the plants should all be sprayed with a one per cent. solution of lime sulphur to prevent attacks by mildew after housing. A good dry day should be chosen so that the plants become quite dry, before being placed indoors, after which abundant air should be given night and day. Feeding should cease as the flowers show colour, but on no account must the plants be allowed to become dry at the roots.

Violets.—Plants which are being grown for frame culture should receive encouragement by frequent hoeing, the removal of all runners, and a good dressing of manure—dried blood for preference. Where possible, copious watering and spraying in hot weather should be practised, and should red spider appear, spraying with lime sulphur should be carried out.

Roses.—The surface of Rose beds should be hoed, and many of the smaller buds removed to increase the size of the flowers retained. Feeding of Roses, either with natural or artificial manures, should now cease, or the growth may be rendered too soft to withstand the winter. Where the growth is very luxuriant a dressing of potash, either as wood-ashes or sulphate of potash, will help to firm it up; the latter fertiliser should be used at not more than one hundredweight per acre.

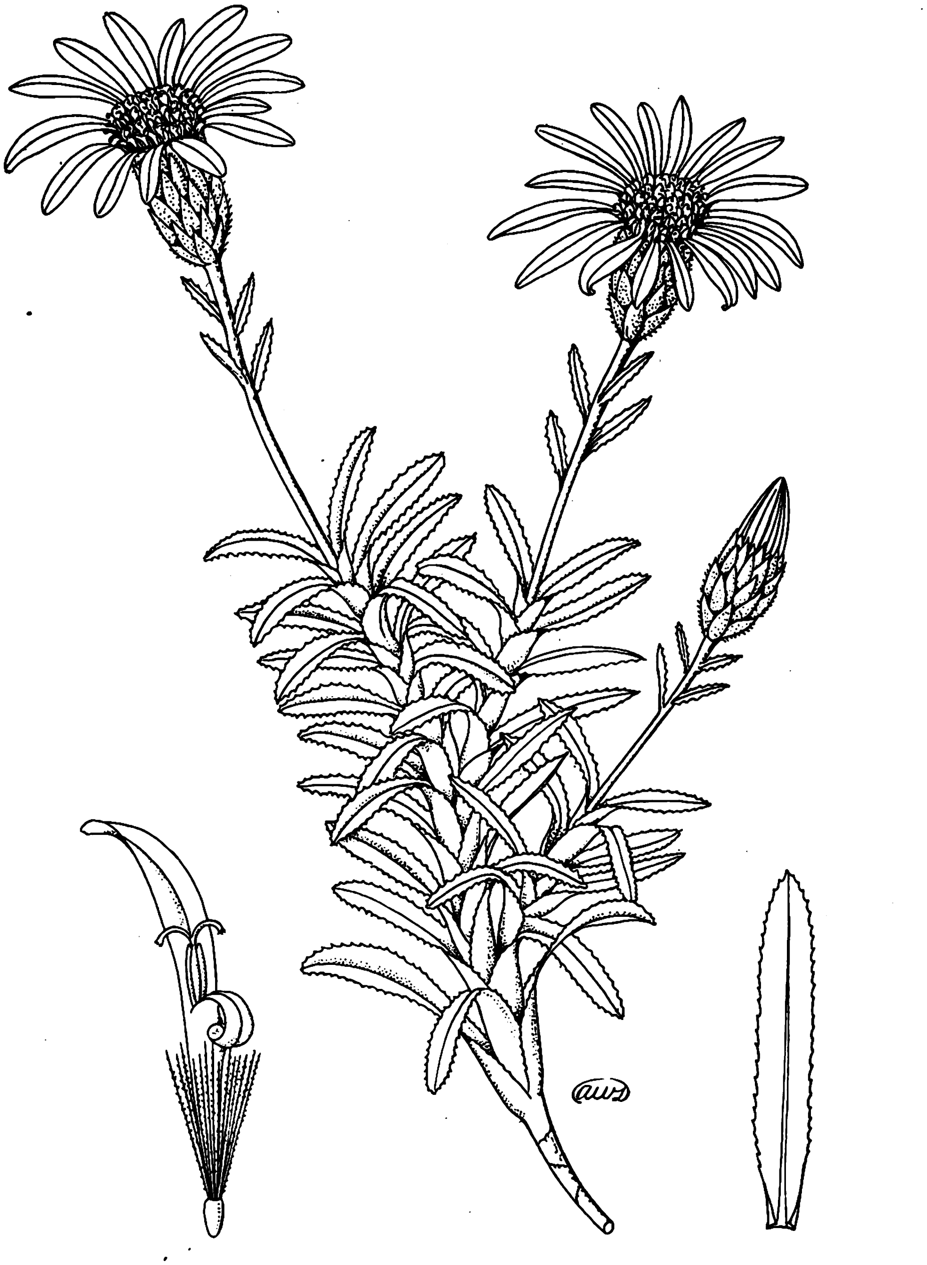

FIG. 80.—PEREZIA RECURVATA.
(see p. 165.)

Propagating Herbaceous Plants.—Many of these can be increased by cuttings put in now in cold frames, and plants so raised give finer results than old clumps. Anthemis, Achillea, Phygelius, Centranthus and many others of like growth lend themselves to such treatment. Others, such as Crambe, Anchusa, Verbascum, Oriental Poppies and so forth, are easily increased by root-cuttings, which may be secured at any time now. Short pieces of the moderately thick roots should be cut into lengths, not over two inches, cut square above and pointed below, tied in small bundles and buried in sharp sand in odd corners out-of-doors. These will form calluses in a short time, when they may be potted singly and grown on in frames until large enough for permanent planting. Others, such as Salvia pratensis, Heucheras, Lychnis, Viscaria, etc., soon deteriorate if left in large clumps, and in our northern climate it is not judicious to break them up in autumn, for planting in the open, so that it is well each year to plant a few of the better-class things in frames of light soil where the slight protection so afforded allows them to become established and ready for planting in March, or later, as may be found convenient.

Strawberries.—When sufficient stock has been secured and heeled in in nursery lines, either on a south border or in a frame, the latter for preference, the beds should be cleared of runners and the surface broken up between the rows. On heavy soils shallow "pointing" is the best and speediest way of getting the work done. If the soil is poor, a good soaking of liquid manure, or a dressing of dried blood, should be given to build up the crowns before growth ceases.

Morello Cherries.—These have again been a heavy crop, and as the fruits are gathered all old wood should be cut away, retaining sufficient young shoots to replace them. Stone fruits suffer less from pruning when the leaves are present than when in a dormant state. Shoots which have reached the top of the wall should be cut away, as spurs are not required on Morellos. On no account should young shoots be tied to older growths so as to form layers of growth, as one sometimes sees, or the vitality of the trees may suffer.

ALPINE GARDEN.

ROSA ROULETTII.

It was with a considerable amount of trepidation that I consigned my solitary plant of the tiny Rosa Roulettii to the open rock garden without any protection last autumn, and had I known of the ordeal of an almost arctic winter which was then before us my hesitation would have been greater still. However, any fears I had were dispelled when this wee Rose came into leaf, and in the third week of June this miniature "Queen of flowers" gave several of its delightful little warm pink flowers. I observed last year a note upon it to the effect that the blooms were crimson, but this is an error, unless there are two or more forms.

These flowers, unlike what one expected from a Rose bearing a botanical specific name, are double, and this year my plant produced them on a tiny bush, some four or five inches high. Now that the hardiness of R. Roulettii seems to be established beyond reasonable doubt it will surely find its way into many a rock garden. One has a vision of thirty, forty or fifty plants forming a group. To the writer this vision will probably remain a phantom indeed, but the possibility will present itself to some who might make a feature of this "smallest Rose in the world," as it has been called, probably with truth. It is not plentiful in the market as yet and one can only hope that over-propagation may not render this little gem less hardy than it has been.

SEDUM EWERSII.

This Sedum is classed by Mr. Lloyd Praeger in his classification of the Sedums in cultivation in what may be called his third group, the first being those very common in cultivation, the second those common, and the third, eleven species which follow in frequency. I think this will be the general experience of those who have worked to any extent upon the Sedums. Mr. Lloyd Praeger classes S. Ewersii in "Series II, Humiliores," and in "Group I, Arctuatae," and gives in his review of the genus, which appeared in the R.H.S. *Journal* for May, 1921, full particulars regarding S. Ewersii, and I must acknowledge my indebtedness to this admirable contribution for much information regarding the plant.

It is a native of the western Himalayas to the Altai, Soongar and Mongolia, is hardy, and flowers in August and September. As Mr. Lloyd Praeger states, it is distinguished among the purple-flowered Sedums by its semi-trailing habit and opposite pairs of clasping leaves. It is a true herbaceous perennial, dying back in winter to a branched, twiggy root-stock. The fleshy, glaucous leaves are entire or faintly toothed, and the flowers are purplish-pink, in cymes. It is a most distinct species and is easily identified after being seen once or twice. Offered as S. Ewersii var. turkestanicum or simply as S. turkestanicum, what is stated to be a darker variety of S. Ewersii appears in some catalogues; Mr. Praeger states: "None of the plants which I have seen under the name were in any way distinct, or worthy of varietal rank."

I had at one time a plant sent as S. turkestanicum, but so far as I remember, it did not differ from S. Ewersii as I then knew it, or what I at present cultivate.

There is, however, a distinct variety, now described by Mr. Lloyd Praeger, which he calls var. homophyllum, and which is to be found in gardens as S. cyaneum, quite a different plant, the name cyaneum being usually wrongly applied to S. E. var. homophyllum. It is a curious little plant almost identical with the type, but dwarfer and with the flowers not borne on the clasping-leaved shoots of the type, but on what answer to the barren shoots.

As a garden plant S. Ewersii is of considerable value. Its late-flowering habit renders it of considerable worth for the rock garden, and it looks well there, but better still on the face of a double wall with earth between, or on a retaining wall. I am growing it at present under the former conditions, and a good plant proves quite a pleasing addition to the attractions of such a wall, associated with other Sedums, encrusted Saxifrages, Gypsophila repens and other rock plants. S. Ewersii may be raised from seeds or propagated by cuttings. *S. Arnott.*

CAMPANULA ARVATICA.

If this delightful Campanula is not one of the easiest, it can hardly be classed among the "difficult." I have had it for a good many years, during which it has not only proved its perennial nature, which was once doubted, but has shown itself capable of surviving some of the most trying winters experienced in our generation. Here it prospers on a sloping, westerly edge which is thoroughly well-drained, the soil being stony with a dry retaining wall immediately below it.

Campanula arvatica is exceedingly dainty in growth, its slender stems trailing lightly over the ground for the space of a few inches and emitting throughout the middle of summer a succession of lovely, wide-rayed stars of a soft purple. The small, pale green leaves, which are rounded and slightly notched, are few, the entire plant suggesting a model of fragile delicacy. This charming little Bellflower is, of course, an ideal rock garden plant and one that should never be omitted from the choicest collection. It is stated to grow on limestone in its native Spain, but it has never had more than a little old mortar with me and even that it could probably do without. *N. Wales.*

CORONILLA CAPPADOCICA.

This essentially sun-loving plant obviously enjoyed the tropical conditions which prevailed during the early part of the season, for it is seldom that one sees it so florally effective as it has been this year. From a perennial rootstock, the annual stems creep along the surface, branching, and forming a thicket of prostrate, terete growths, the tips of which may rise six inches from the surface. It flowers as it creeps along, the umbels nestling in a glaucous mat formed by the long, narrow, imparipinnate foliage. The seven to nine individual blooms in each umbel are in a single row, of one plane, forming a ring one-and-a-half inch in diameter. They appear to be clear yellow, until, looking closely, it is seen that dark rays pencil the standard petal of each flower.

The method of propagation recommended is by division of the roots, in early spring, but, as with other members of the Leguminosae, this operation requires to be carefully performed. It may also be raised from seeds, which should be sown so soon as ripe. The young plants should be planted in light, calcareous soil in their permanent positions the following spring, choosing, for preference, a warm, sunny, well-drained pocket in the rock-garden. *Jonathan Fiona.*

SOME DECORATIVE ALLIUMS.

Mr. Arnott's note on Allium triquetrum (p. 29), followed by *M. W.'s* on A. narcissiflorum in your issue of July 27 (p. 67), brings to mind a crowd of other excellent plants belonging to this huge Liliaceous race, from wee A. Purdomi to giants like A. albopilosum, and giving flowers in many shades of colour—yellow, white, blue, lilac, pink and crimson. There are about 350 species known. Of those in cultivation, it is only possible here to "select out a few for this our garden whose flowers for their beauty of stateliness, form or colour are fit to be entertained and take place therein," as Parkinson states in his *Paradise in Sole*, omitting such as "will hardly abide the extremity of our sharpe winters." They are mostly of easy culture, given a light soil and a sunny place, although many do equally well in half-shade, and some can fend for themselves under almost any conditions, even becoming weeds.

To this latter class belongs A. Moly, the golden Lily Leek of Pyrenean woods. This has been long in English gardens. Parkinson knew it well and, describing it in pre-Linnean fashion as Moly montanom latifolium luteo flore, remarks upon its quickness of increase. The leaves are glaucous, "neare the bignesse of a reasonable Tulipa leafe" and like one in shape. The large flowers are gathered into broad, flat umbells upheld by sturdy nine-inch stems, and make a brilliant show of yellow for the front of the border. The plant multiplies rapidly and is one of the most useful Garlics we have, being cheap, easy, vigorous and beautiful. It flowers in early June.

About the same time comes the huge and globular, dull purplish heads of A. karataviense, a Turkestan species for any odd corner, where its paired, glaucous leaves will be very attractive during April and May. Also June-flowering, and from Turkestan, A. Ostrowskianum is an alpine of great merit indeed, capping its six-inch stems with umbels of bright rosy flowers. These are more or less triangular in shape the three inner segments being much smaller than the outer three, and their colour is a beautiful warm pink, very different from the "rich dark red violet" of Farrer's description. The leaves are narrow and channelled, and about four inches long. A. Ostrowskianum is not difficult, although too choice and small for anywhere but a sunny position on the rock garden.

A. albopilosum brings us back to the herbaceous border, where its massive balls of lilac are always sure of attention, however spidery the individual flowers may be with their six long and narrow segments radiating from the ovary like the spokes of a wheel. This Persian Garlic is a plant of astounding size, its head measuring about nine inches across, and the stem towering to five feet. A. Rosenbachianum is another border plant with lilac flowers, more graceful than A. albopilosum and not so tall.

Coming to English gardens from Siberia, A. azureum (A. coeruleum) sends up in June, from its narrow, grassy foliage, slender stems of eighteen inches, each tip-clustered with a ball of bright blue flowers. These "drumsticks" are very handsome, but their stalks are so liable to snap in the wind that it is advisable to give them a sheltered position. Flowering with A. azureum, but possessed of, as yet, no official title, A. sp. Thibet, is a neat Garlic, which grows about nine inches high, and has narrow, linear leaves. Its flowers are tubular and small, forming a drooping umbel of reddish-purple.

A. cyaneum and A. kansuense resemble A. sp. Thibet, in general habit, bearing their blue flowers in graceful, pendant clusters at a time when colour on the rock garden becomes daily more precious, and when all of their kindred, except A. roseum and A. sphaerocephalum, have finished flowering. The latter has big, conical heads of crimson flowers, with a few leaves sparsely sheathed around the base of its two-feet stalk. It makes a fine border plant and can be used with effect on the rock garden, in association with Thymes. A. cyaneum and A. kansuense are smaller than this, A. kansuense, swinging its bells on stems from nine to twelve inches high while A. cyaneum rarely rises above six inches. They both come from the steep hillsides of Kansu and are so closely allied that Regel at one time considered them forms of the same species, A. cyaneum being distinguished as A. cyaneum var. macrostemon by the way its stamens project beyond the cup of the perianth, and A. kansuense as A. cyaneum var. dasystemon, since the stamens here remain within the permanently tubular flower. This is the Allium illustrated as A. cyaneum var. macrostemon in Farrer's *English Rock Garden*. It has tapering, channelled leaves and starts flowering a week or more ahead of A. cyaneum. Its flowers are coloured a clear and delicate blue, like that of Agapanthus umbellatus; there is no dark line of green or blue down the middle of each segment, such as in A. cyaneum, and the flowers do not open so widely. In A. kansuense the membranous spathe, which covers the buds, drops off as the buds begin to develop. A. cyaneum, on the other hand, retains its spathe, and has much daintier foliage, its slender, rolled and needle-like leaves suggesting a tussock of Festuca ovina, while its flowering stems are shorter than those of A. kansiense. For growing in the sunk garden of choice alpines, A. cyaneum is the more suitable plant; on the rock garden it must always yield to A. kansuense, with its larger heads and brighter colour, winsome and precious as it is. Both of these Alliums seed freely, but separation and replanting of their small bulbs offers the readiest means of increase. It is best to buy them as established plants in pots, as these may be put in at any time.

A. kansuense is figured in the *Botanical Magazine*, t. 7,290, not t. 6,451, as Mr. Edwards states in his article on A. Beesianum (*Gardeners' Chronicle*, April 13, 1929). That plate shows A. karataviense! *W. T. Stearn, Cambridge.*

TREES AND SHRUBS.

AZARA GILLIESII.

THE better known species of Azara—A. dentata and A. microphylla—are justly popular shrubs or small trees, but A. Gilliesii is assuredly deserving of greater prominence than it receives. It is not, perhaps, quite so hardy as its congeners, although A. dentata sometimes resents severe weather, and will appreciate the protection afforded by a wall, where the reddish-tinted branches and somewhat Holly-like leaves will prove an attraction. The yellow flowers are produced in winter or early spring, the axillary panicles being densely crowded with the small blossoms; the ovate, coarsely-toothed leaves of this evergreen subject are very smooth and are coloured a cheerful green.

This interesting shrub grows well in good loamy soil, and considering that it was introduced from Chili so long ago as 1859, it is surprising that it is not found more frequently in gardens; A. Gilliesii is figured in the *Bot. Mag.*, t. 5,178. *Ralph E. Arnold.*

CASSINIA VAUVILLIERSII.

THIS species of Cassinia, although not rare, is much less grown than the allied C. fulvida, with its golden, Heath-like foliage, which is so pretty in winter. C. Vauvilliersii, on the other hand, has silvery foliage, which is also exceedingly attractive in winter. In addition to the usual form, which is inclined to droop over, there is a variety named C. V. var. erecta of erect habit of growth. I am writing this note on C. Vauvilliersii in view of its hardiness here, it having survived here (Dumfriesshire) during the past two seasons against a south-west wall without protection. *A.*

HARDY FLOWER BORDER.

OTHONNOPSIS CHEIRIFOLIA.

SOME works of reference class Othonnopsis cheirifolia, the Barbery Ragwort, as a "greenhouse sub-shrub." In reality, however, it may be more correctly called a hardy plant, as it is rarely that it suffers in winter, even in a cold district, if in a dry position. It has been known in British gardens many years, as it was introduced in 1752. It has long been called Othonna cheirifolia, but has now been recognised as being the representative or possibly sole member of the genus Othonnopsis, signifying "like an Othonna." It was figured in the *Botanical Register*, t. 266. It is a member of the Natural Order Compositae.

O. cheirifolia owes its attractions mainly to its foliage, which is flat, broad, and of a glaucous appearance. It more resembles in respect to its foliage a Sedum than anything else in the way of outdoor plants. The flowers, which are bright yellow, are disappointing when seen on a small plant. They are more like a small-flowered single African Marigold than any other well-known flower which the writer can recall. The whole plant is about a foot high when in flower. It is best suited to the large rock garden but may also be employed in the front of an herbaceous border. It ought to have a very dry, well-drained soil and a sunny position. In a mass it presents a much better appearance than when grown as a single plant, and last summer the writer saw a big group in full flower in an extensive rock garden, which gave him a better idea of the worth of the plant than he obtained from having grown a few plants for a number of years. It was quite a satisfactory plant for the good position it occupied, and covered a space of about three feet each way. It was quite hardy there, and the writer has grown it in a fairly exposed position for a number of years, and it was only slightly injured in a specially hard winter. It is easily increased by cuttings and seeds, if the latter can be obtained. It flowers from May onwards, but, as already suggested, its principal value is because of its foliage, which is quite attractive all the year round. *S. A.*

ROSE GARDEN.

ROSE WICHURAIANA.

I HAVE read with pleasure the note by Mr. A. Osborn, in "Notes from Kew" (p. 129) upon Rosa Wichuraiana, and its value as a trailer over banks and rockwork. It is strange that the typical R. Wichuraiana is so rarely seen, even in gardens where the Rose species are largely cultivated. It deserves all that has been written in its favour by Mr. Osborn, and one can only add that it looks very attractive over slender arches. I once had it growing over such an arch, and it was highly pleasing, with its glossy leaves and good, single, white, fragrant flowers. After removing from this garden, when it was left, I resolved to plant the type in rather greater numbers, and to grow it over a trellis. With this in view, I purchased a dozen plants, but all were inferior to the one I had before. They seemed to be seedlings, and varied considerably in freedom of growth, glossiness of foliage and in size and form of the flowers. Hence, I think, it would be advisable for any one procuring the typical R. Wichuraiana to see the plants in flower and to select only good forms. *S. Arnott.*

FLOWER GARDEN.

GAZANIAS.

THIS strictly South African genus has revelled in our hot dry summer. Fig. 79 (p. 159) shows a hot dry border in St. James's Park containing about one thousand plants. While the major portion consists of the well-known G. rigens (syn. splendens), there is a sprinkling of the more recent introductions from South Africa, including the wonderful G. Pavonia, with its almost scarlet flowers and pinnate leaves, and also white and yellow self-coloured varieties.

Thanks to the renewed interest in South African plants there are now in cultivation many varieties and species of Gazanias, and although in limited quantities at the moment, it will be but a short time before they make their bow to the public, and it may confidently be expected that this one-time favourite is about to enjoy another spell of popularity.

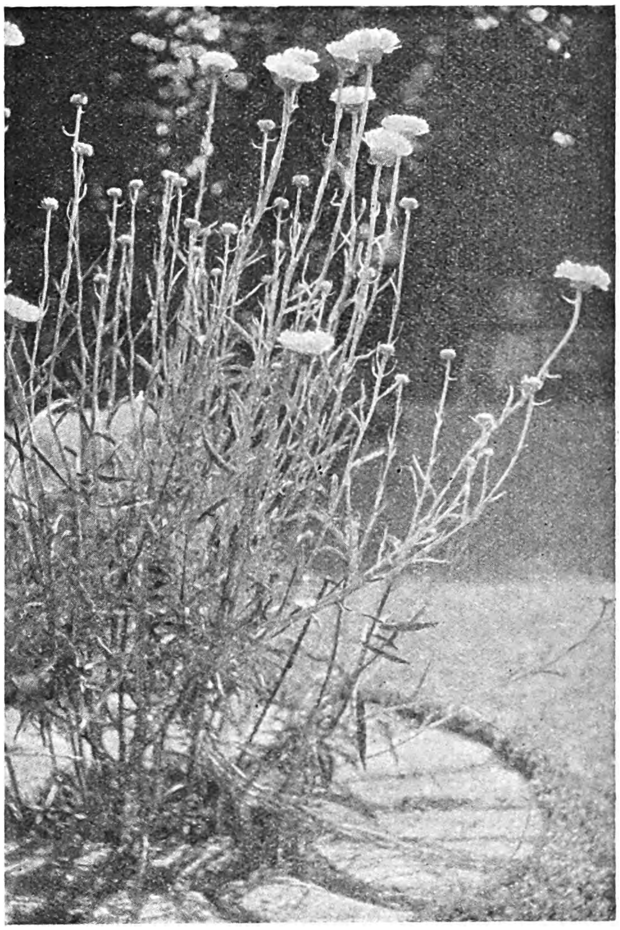

FIG. 81.—GRINDELIA SPECIOSA.
(see p. 165.)

The number of varieties now in cultivation is far more numerous than in pre-war days, when it was possible to secure several varieties raised on the continent. These seem to have been lost, but the best of them could not compare with what South Africa has now provided. The newcomers are endless in their shades of colour, markings and size, and have great diversity of foliage.

The identification of Gazania species is by no means easy, and the layman, even with both the French and the English Monographs before him, would have great difficulty in deciding which are hybrids and which are species.

No doubt it will be found that the species cross readily in their native habitat. Gazania seeds may be purchased from South Africa and possibly some British seedsmen. They are easy to raise and whether sown in spring or autumn, will give plants that flower within the year from seed-sowing. They are fascinating subjects to grow from seeds, and one day that much discussed purple-flowered species may be hoped for. *T. Hay, Hyde Park.*

INDOOR PLANTS.

COMBRETUM PURPUREUM.

This handsome evergreen climber, of moderate growth, is splendidly adapted for covering the pillars or the rafters of a warm house; it is most effective in the latter position, as then the purplish-crimson, almost scarlet, blossoms are seen to the best advantage. The flowers are produced in July, in large racemes, and present a brilliant spectacle; the plant thrives in peat, and is easily propagated from side-shoots obtained with a heel and inserted in sand, or very sandy soil, in a propagating case over bottom heat. The minimum summer temperature should range from 60° to 65° F. and the minimum winter temperature from 50° to 55° F.

A native of tropical America, Combretum purpureum will enjoy a humid atmosphere and sufficient shade to prevent scorching. It should be more widely grown, for it is a plant of striking beauty and considerable charm; its wreath-like sprays are invaluable for high-class decorative work. *Ralph E. Arnold.*

PHYSOSTELMA WALLICHII.

This beautiful, although rather peculiar, flowering stove climber is the only one of a genus of two species in cultivation. P. Wallichii is sometimes known under the name P. campanulatum; a native of the Malayan Archipelago, it was introduced from Singapore in 1845.

The waxy, cream-coloured flowers, tinged with purple, are broadly campanulate, and are borne, numbering a dozen or more, in a pendulous, umbelliform cyme. The individual blooms are between three-quarters-of-an-inch and an inch in diameter, and smell faintly of Lemon, reminding one of Lippia and Eucalyptus citriodora. The calyx is small and insignificant and finely parted.

The cultivation of this beautiful plant presents no great difficulty. It prefers a well-drained, peaty soil, and will thrive best trained against a wall, from whence it will derive additional moisture. It produces an abundance of blooms, too, when grown on peat pillars. These are made by procuring a large pot, crocked in the usual way. A stout, Oak post, three or four feet long, is firmly fixed upright in the centre of the pot by means of ramming peat tightly round about it. Peat is fixed around this post to the top and flush with the outside edge of the plant-pot. Some support is necessary to hold the medium together; this is given by putting a piece of good, close-mesh wire-netting round the outside of the pillar, It may be found best to fix this support first and ram the peat in afterwards. The young plants are placed in and trained around the pillar. It is advisable to make the top saucer-shaped to facilitate watering.

P. Wallichii belongs to the Natural Order Asclepiadeae. *F. H. Wright, Cambridge Botanic Garden.*

TRACHYMENE COERULEA.

Nicholson, in his *Dictionary of Gardening,* does not refer to Trachymene (Didiscus) coerulea in very complimentary terms, and yet it is an uncommon and highly decorative subject when grown in pots for a summer display in the cool greenhouse. It is a half-hardy annual, and when grown for cool greenhouse decoration the seeds should be sown in mild heat in early spring. The large, flat seeds should be spaced about half-an-inch apart to allow the seedlings room to develop before pricking them off into three-inch pots. It is a thin-growing plant and from three to five seedlings should be placed in each receptacle. The young plants should be kept growing in a warm greenhouse and potted on into five-inch pots, and later into the flowering pots, six or seven inches in diameter.

Trachymene coerulea starts to flower when about eighteen inches high, and continuing growing and flowering, eventually attains a height of over three feet. The individual, five petalled flowers, each a quarter-of-an-inch in diameter and pale blue in colour, are borne in umbels of fifty or more blooms. The umbel opens flat, but by the downward lengthening of the outer rows of flowers is, when fully expanded, globular in outline. After fertilisation the usually sterile, outer flowers assume a perpendicular position, closing over the mass of seed-bearing, inner flowers. *Jonathan Fiona.*

FLORISTS' FLOWERS.

BORDER CARNATIONS.

If an annual show of any flower only served to define clearly the superiority of certain varieties for show purposes, both as regards pot and border culture, it would achieve its object, for there is always a class of amateur growers who prefer to wait and see what is likely to prove a sound investment, mistrusting their own ability to make a discriminating choice, although this takes away a great deal of the pleasure one obtains in having a novelty which has to justify its reputation. Certainly there is always the chance that new varieties will not fulfil their early promise, some very soon degenerating or showing traits not at first apparent, reversion to an inferior type sometimes happening, but if the majority of gardeners reasoned in this manner it would be a very small band of the elect who tried out the many lovely things put on the market, season after season.

Two varieties especially may be mentioned as having been much decried, and yet are probably now more universally grown than most—Mary Murray and Mrs. E. Charrington—the former being dubbed coarse and deficient in layers in its first seasons, while it seemed as if the latter was one great mistake, but time has proved it to be the most acclaimed white-ground Fancy, which, when grown as shown by Miss Shiffner at Vincent Square, in July, no one could dispute. I agree that Mary Murray may be very chary as regards layers, but I believe this to be only a matter of soil and position. I have grown the variety in many aspects, in soil on the light side, but it requires, as all classes of Carnations do, except the yellow-ground Fancies and Picotees—which will do well in much lighter soil than the others—a fairly heavy medium and a south-west aspect, which seems quite as necessary as the soil, and is at all times the ideal position for these flowers. Given these, the beautiful yellow Self will be at its best, and this is very good, including a stem which is second to none, and ten to a dozen strong shoots where the stock has been grown from healthy plants. This, again, raises the question as to how far it is safe, or even permissible, to layer from plants which have had to be heavily fertilised for show purposes.

To assume that because a variety gives large blooms after being treated in this way, especially if chemicals are used, that the shoots, when layered, will not show the weakness which is, in the first instance, caused by drugs administered to give a fictitious strength, is to shut one's eyes to what will speedily prove a very obvious fact, for when propagation is thus systematically effected from show stock, the result will be that the shoots become so poor and weak that in many instances, if one requires to perpetuate the variety, the layers have to be grown on for a year, nipping out the flowering stems, before they are of any use whatever. Only by having sufficient stock to enable one to keep for that purpose alone the plants intended for the showboard, layering from the remainder which have been fertilised sparingly in the ordinary manner, can healthy plants be assured, and by this means most of the losses caused by stem-rot, would, I am confident, be eliminated. Those who grow from stock which they know has never been used for exhibition purposes are rarely troubled by this disease, and if one or two plants do occasionally succumb, it is generally traceable to an entirely different cause, soil pests being liable to breed, however careful one may be.

Weakness and delicacy of constitution are not natural to the hardy border Carnation, and the very fact that the ravages caused by stem-rot and other diseases (one of which is a gradual hardening of the stems, with sapless conditions, which I am trying to elucidate, and which seems to puzzle all who have observed it) have become much more serious, especially in certain districts, point to the opinion that the cause must, in the first instance, be induced by Carnationists themselves, for the pioneers who were so careful to note and examine any defect do not make any particular reference to what is fast becoming a menace to the border Carnation.

On light soil, I have found that sand is quite unnecessary where old mortar-rubble, which contains sand in abundance, is used freely, also an occasional dressing of pulverised limestone is preferable to lime, which renders the ground too friable, and where wood-ash is used, which on light soil I deprecate, an excess of potash, in addition to that in the soil already freed by the lime, may very easily result in an attack of rust. Carnations will grow in any good soil, but will thrive all the better if a knowledge of what to avoid, and the requirements of different soils, are kept in view.

To return to the flowers themselves, two other varieties which unfailingly appear on the show-board are Highland Mary and Bookham Scarlet. That the latter is a very excellent Carnation is granted, and there are now about five more scarlet Selfs which may be grown with advantage—Red Gauntlett, E. Lyall Sweete, Flambeau, Fusilier and Regina, the last especially good in the border. Flambeau and Fusilier are novelties. The former, of a brighter colour than most, will become popular on that account, if it is a strong grower in the open.

A new French lavender-grey Self, Misty Morn, should, according to its reputation, supply a long-felt want in this shade, being a variety with stiff stems, good shape and habit of growth, and suitable for exhibition from pot or border—a rare combination where this colour is concerned. It certainly is a charming thing, and together with Kate Seton, a white-ground Fancy, heavily marked with rose-pink, gained a First Class Certificate at Vincent Square in July. The latter promises to be a great success when put into commerce.

Other quite new varieties are Fancy Free, a very dainty flower of Fairy Clove colouring, but with rather thin petals; Coldstreamer, buff-ground Fancy, heavily marked and suffused with scarlet, which recalls other varieties of very similar colouring; Homer, a rose-madder Self, with exceptionally stiff stems; and a Fancy, Prince John, in colour a cross between Ebor and Verdun, but very unevenly marked, some of the petals being entirely of one colour, placed here and there in the bloom. It is a large flower, and, if a strong grower, would add gaiety to the border.

Three Fancies shown as seedlings last year, and which I noted in a former article, are being sent out this autumn, *i.e.,* Aspasia and Luki, yellow-grounds; and Egeria, white-ground with deep crimson edging. The first-named is a seedling from Highland Mary, and somewhat of that colouring, with denser markings; Luki is of a somewhat unique deep yellow with maroon and crimson markings, the nearest to it in these shades being Allan-a-Dale, but it is a curious fact that if an outstanding flower is raised there will, very shortly, be several of similar colouring, although nothing approaching it had previously been seen; Kelso is a case in point.

A yellow Self named Undine, another novelty for this autumn, is stated to have a Clove scent—surely the only one in existence—but it looks strong, if somewhat cupped. As these are all still to be proved, amateurs must take their choice.

Many varieties sent out during the last few seasons have justified themselves by growing freely and strongly, without any protection, in the open border; four white-ground Fancies which are very similarly marked, but in different colours, are Bookham Beau, Fred Archer, Flora McIvor and Alice Forbes; Monica, Yenton, May Morning and Evelyn White are also of exhibition form. So far as their habit is concerned, there is nothing to choose between them, and I can recommend all, the first-named having a flat type of bloom like St. Clair Amos, but it is most floriferous and lasts well.

So far as new yellow-ground Fancies are concerned, there is none better than Florence Grisby, a beautiful, strong, lasting variety, while Idwen will please amateurs who want the Kelso colouring in the border. Plant this facing south-west in firm loam. Another of the type, and a giant in growth, is King's Jester. I do not think either Highland Mary or Viceroy can be bettered, but to these I would add J. J. Keen, a perfect flower, Kathee Moore and the newer varieties Radio—worth a trial as being decidedly noticeable as to colouring—Vega, deep yellow, heavily marked with brightest rose, a very fine flower, and Vesta, heavily marked with maroon.

In Selfs, the purple Majestic, certificated last season, a strong grower of excellent shape and size, and of outstanding colour, and the dark lavender Jim Dalton, will prove good for any purpose, the border suiting both varieties to perfection. Others of equal merit are St. Joan, "Ashes of Roses" shade; Ibis, an older variety, lovely salmon-scarlet; Bookham Pink, a really good rose-pink, of exhibition form; and Teviotdale, a distinct and telling shade of ruby-rose, strong and floriferous. St. Joan is rather inclined to be cupped, and the Dianthus blotch of deep rose is very marked at the base of the petals in some of the blooms. I do not recall any other variety which has this trait, but it is of perfect shape, and so strong and unique in colouring that it is a universal favourite.

The Cloves are enriched by Breckenborough Hall, the seedling from Mrs. A. Brotherston, not only on account of perfume, for it is of strong, compact growth, and its colour, a charming salmon and pale pink, ticked with red, marks it out very distinctly; and Edenside Clove, a heavily-marked white-ground in the style of Ravenswood; this latter, exhibited at Vincent Square, is not yet in commerce.

Other varieties and points of interest to Carnation lovers must be included in a future paper. *J. B. Wells.*]

PLANTS NEW OR NOTEWORTHY.

PEREZIA RECURVATA.

PEREZIA recurvata, Loss., is a desirable dwarf, sub-shrubby perennial. It is a member of the great Natural Order Compositae, and hails from the far distant Falkland Islands, where it grows in peaty and sandy soil, usually among rocks on, or not far distant from, the coast line. It forms a compact, densely leafy tuft of evergreen, grey-green foliage, usually well under a foot in height, frequently only three or four inches in exposed places, in nearly pure sea-sand.

The branched stem (Fig. 80) is clothed with tough, strap-shaped, recurved leaves, usually not more than an inch long, with sharply-toothed margins; their tips are rather pointed, or blunt, and the base is dilated into a sheath which clasps the stem. The blossoms are terminal, on the ends of slender, woody stalks one inch or two inches long, clothed with a few reduced leaves just under the involucre, which is composed of about three rows of overlapping bracts, furnished on their edges with stiff, spiny hairs. The florets are sometimes lilac, or white, but are usually of a beautiful deep rich blue colour and are very fragrant.

In its native habitat, where it is known as "Lavender," the blossoms of Perezia recurvata are produced during the months of December and January. As the climate of the Falkland Islands resembles that of western Britain, the plant should prove quite hardy in such localities, in sandy peat, in an open spot in the rock garden, where it should prove attractive even when out of flower by reason of its uncommon-looking greyish foliage. *A. W. D.*

CALCEOLARIA VALDIVIANA, COMBER, No. 790.

THIS herbaceous Calceolaria (Fig. 82), raised from seeds collected by Mr. H. Comber in the Andes, has proved a plant of considerable garden merit. The purple-coloured, branched flower stems, of which there are a dozen or more to each plant, rise to a height of two feet six inches, and bear beautiful flat, clear-yellow flowers, of good lasting quality. The plant seems to be quite hardy, having withstood last winter without injury. Other Calceolarias from the Andes are doing equally well and self-sown seedlings are growing freely.

GRINDELIA SPECIOSA, COMBER, No. 33.

THE flowers of this plant are four inches in diameter and are borne singly at the end of a stiff stalk three feet in length. The foliage is sparce. The flower buds are covered with a white, sticky gum for some weeks before they open. (Fig. 81.) *K. McDouall, Logan.*

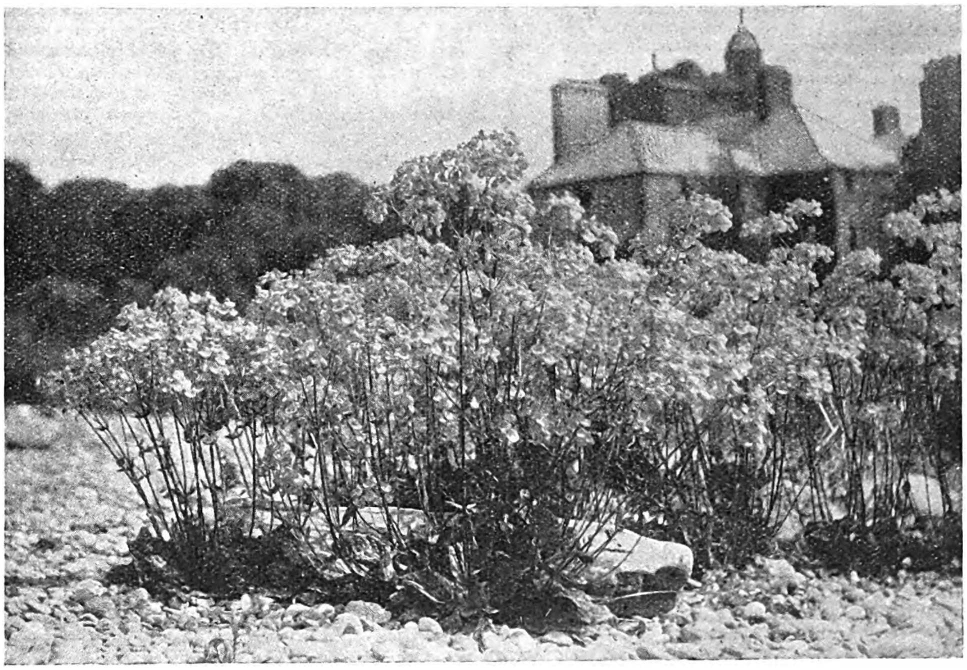

FIG. 82.—CALCEOLARIA VALDIVIANA.

GARDEN NOTES FROM SOUTH-WEST SCOTLAND.

PLANTS of one genus differ very widely from those of another genus in the degree by which they reveal or disguise kinship. It requires, for instance, close scrutiny with a lens to show that Olearia Lyallii, with its leathery leaves eight inches long, belongs to the same genus as O. virgata, which bears small, linear leaves set in fascicles along the slender branchlets. On the other hand, no species of St. John's Wort can deceive the most superficial observer about its genus, although centuries of a marshy environment have imposed a feeble camouflage on our native Hypericum elodes. Most, if not all, of the shrubby species make their chief display in August, and very fine it is. Among the patulum group, I incline to give the palm to H. patulum var. Forrestii, which, as it is not included in the Kew *Hand List*, may, like H. patulum var. Henryi, be no more than a geographical form of H. patulum.

Both H. patulum var. Forrestii and H. patulum var. Henryi are perfectly hardy, whereas H. patulum type is frost tender, and need not be attempted except in very mild districts, unless against a wall. Moreover, the two varieties concentrate their splendour, covering their shapely mass with golden blossoms during a full fortnight, while H. patulum is never so effective, flowering less profusely, but continuing to do so after the others are passed, until stopped by frost. The gold of H. Hookerianum is quite as pure as that of others in the group, but it has not the compact habit which contributes such decorative effect to H. p. var. Forrestii and H. p. var. Henryi. It inclines to be leggy and flowers later than they. I well remember my first introduction to this species. Full fifty years ago, when strolling through that tangled treasure field of good things—Messrs. Cunningham and Fraser's nursery, in Edinburgh (now, alas! no more), I came upon a single plant among some Gooseberry bushes. I secured it and have never since been without its progeny.

I am grateful to the kind friend who last year sent me a plant of Rudbeckia flava, which, I suppose, is a new species, as it is not entered in the Kew *Hand List*. It bears a general resemblance to the North American R. speciosa; but the yellow rays are flatter and rather broader than in that species. Moreover, it begins to flower in June, a full month earlier than R. speciosa, and is still putting forth fresh flowers—in mid-August.

We ransack mountain and plain all over the world for furnishing our borders, and no doubt secure a rich reward; but sometimes it is brought home to one that some of our native herbs, if relieved from the struggle for existence to which they are exposed in their natural environment, prove lusty rivals in beauty to many a high-priced exotic. My eye was attracted lately by a mass of blue in a border of Roses, where no such colour had been assigned a place. It proved, on near approach, to be a cluster of Bluebells—not the English, but the Scottish Bluebell (Campanula rotundifolia), which, self-sown from the fields, had grown into a dense clump fully eighteen inches high, and thickly hung with its pretty flowers. In the wild it would have had to compete with grass and other herbage, and could never have borne the profusion of flowers which attracted me.

The Indian Strawberry—Fragaria indica—is one of Nature's most successful practical jokes. Its bright yellow flowers are succeeded by Strawberries of the richest crimson, but totally devoid of succulence. Rambling as it does here on a retaining wall, goodness knows how many children—nay, adults also—have been deceived and disappointed by what have all the semblance of refreshing fruits. *Herbert Maxwell, Monreith.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London, W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER ; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar, 7818.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

CURIOUS OLD BELIEFS ABOUT MEDICINAL HERBS.

FEW things are more pleasant on a warm, summer day than to lounge in an old-world garden, enjoying the blaze of colour and the fragrance of the flowers, and so let one's mind wander idly in the realm of fantasy which our forefathers built up around plants.

Hardly a flower in the garden but has some curious legend or belief attached to it, evidence of the important part plants played in the life of primitive men.

From plants the first medicines were obtained —no wonder the ancients endowed them with magical properties and invented marvellous legends to account for these.

One of the most curious beliefs about the medicinal virtues of herbs is that known as the Doctrine of Signatures. No one knows who invented this idea. It seems, indeed, gradually to have been built up. Way back in the thirteenth century, Roger Bacon, in a book dealing with the Cure of Old Age and the Preservation of Youth, wrote that " Wheresoever God hath placed an admirable virtue, he hath added a certain similitude, that every man, who is of a clear and vivacious wit and understanding, may conceive its operation." There are, however, many earlier intimations of the same idea, which was vigorously championed in the sixteenth century by the great Paracelsus and gained almost universal acceptance.

By their form or by some peculiar mark in them, plants, it was thought, revealed their uses to mankind. Sometimes it was said that the mark was impressed upon the plant by a star, for in those days everyone believed in astrology. The stars were the means Divinity used to shape our ends, and the herbs of the field bore their signatures.

In some cases, no doubt, the " signature " was discovered after the herb had been found to be of real medicinal value. But not infrequently, quite useless herbs were prescribed because of some peculiar mark they bore. Thus, both Wood Sorrel (Oxalis Acetosella) and Spotted Medick (Medicago maculata, syn. M. arabica) were used medicinally for heart diseases, the first because of its heart-shaped leaves, the second for the additional reason that its leaflets bear, in the language of an old herbalist, " the perfect icon of a heart in its proper colour."

Many other examples of this quaint old belief could be given, and, in quite a number of cases, plant names bear witness how widespread it was. Thus Euphrasia officinalis, a little plant with a dark-coloured, pupil-like spot on its corolla, was used for improving the sight, and is still called Eyebright. Lungwort (Pulmonaria officinalis)—a favourite plant in old-fashioned gardens—is so named because its spotted leaves were thought to resemble lungs and to indicate its utility in pulmonary complaints. The Lesser Celandine (Ranunculus Ficaria) is still known as Pilewort in some parts of the country, because the curious character of its roots stamped it as a cure for hemorrhoids. Aristolochia Clematitis gets its name of Birthwort from the peculiar shape of its corolla, which, it was thought, indicated the usefulness of the plant in maternity cases. And a whole family of plants derives its name of Scrophulariaceae from the fact that the roots of the Figwort, Scrophularia nodosa, have gland-like tubers attached to them, which indicated that the plant was to be used in treating scrofulous glands of the neck.

A whole book could be written about Mandrake (Atropa Mandragora), so many are the legends attached to this plant, whose forked roots somewhat resemble a little man in shape. In Old Testament times, Hebrew women used it as a cure for sterility. A belief in the magical powers of Mandrake can even be found to-day in some villages in England—roots of the White Bryony (Bryonia dioica), trimmed to shape, usually masquerading as the real article.

The Doctrine of Signatures has been called " the most absurd and preposterous hypothesis that has disgraced the annals of medicine." This is too harsh a criticism of a poetic fancy, which, if it contained little or no truth, at any rate caused men to examine plants more closely and to study their medicinal uses. We may still amuse ourselves in our gardens to-day by examining our plants for " signatures " and letting our imaginations wander for a while in the pleasant region of fantasy. *H. S. Redgrove.*

A FEW NEW ZEALAND OURISIAS.

THE genus Ourisia, which is distinctly of sub-antarctic origin, extends from Andine South America to Tasmania, showing a partiality for mountains wherever it is found. There are some twenty-five species and the genus is well represented in New Zealand, where ten species—all endemic—are found in habitats ranging from sea-level to 6,000 feet. Many of these desirable little gems have not yet come under the care of horticulturists, although they are comparatively easy to establish and all are of pleasing habit, extending into colonies of varying heights and sizes by means of creeping rhizomes. The majority are members of the plant communities which hail from the alpine meadows and, therefore, they should be quite hardy and prove themselves to be popular additions to the rock gardens of the British Isles.

There are two distinct types of Ourisia, but that need not worry anyone unfamiliar with the New Zealand species, because the types may be readily identified by their habits. One group, of which O. macrocarpa is a typical example, is erect in habit, sometimes decumbent at the base, with more or less tender, broad green leaves, usually radical. The blossoms are borne after the fashion of the "Candelabra" Primulas, which is probably the reason why these Ourisias are sometimes termed the " Native Primroses." Members of this big-leaved group are usually found in shady places by the edge of the forest, or in the scrubland immediately adjoining, because, seemingly, they prefer the cool, moist places where forest and moorland meet, where they can get all the light they require but are suitably placed to receive the benefit of the cool shadows of the forest to shield them from the hot sunshine.

The leaves of the various species decrease in size and become more stiff and leathery the farther they emerge from the forest or the higher the altitude to which they climb.

Those belonging to the second group are of more robust constitution and prefer to make their home in the wide, open spaces of the alpine meadow lands, instead of leading the comparatively sheltered life by the edge of the forest, or in the straggling shrubland just above—which often resembles a miniature forest. They refuse to be hemmed in by the tangled life of the forest or scrubland, and so they migrate to the open moors; not content with this some of them climb upwards until they reach the limit of vegetation and there they, perforce, settle down to become pioneers in the colonising of glacial moraines and other uninviting-looking places.

Here they flourish with their bright little faces revelling in the sunlight while their toes and ankles are bathed in the ever-moving moisture which is percolating down the mountain side, beginning its long journey to the ocean. These pioneers, which sometimes reach 6,000 feet altitude, have a very different habitat from their kinsfolk of the lower levels, and, therefore, they tend to become carpet-forming plants of low, creeping, usually closely-matted habit. This growth-form seems to be most suited for enabling them to shelter as best they may from the severe climatic conditions of such a site.

Ourisia macrocarpa (Fig. 83) is one of the very few New Zealand plants which are suitable for cultivation in the herbaceous border. It is the hardiest species of the erect-growing group and when it reaches full development it is a remarkably fine plant, with a quiet charm which is all its own. The stout stems are produced from short, creeping rhizomes and under favourable conditions they rise to as much as two feet in height. The leaves are chiefly radical, three to five inches long, broadly-oblong and more or less sub-cordate at the base. The leaf is dark green above and paler beneath, with dark purple veins and petioles which stand out in bold relief. The dainty, white, Primula-like flowers are borne in from four to eight super-imposed whorls on stems some twenty inches high. The whole plant is glabrous or nearly so, characters which, along with the large sepals and purple veins and petioles, are the chief marks of distinction between this and the following species.

O. macrophylla is rather a tender plant, although closely allied to O. macrocarpa. It belongs to the same group and in its full glory it is really a highly ornamental subject. It may be readily distinguished from specimens of O. macrocarpa by its smaller size, less robust habit, the comparatively large, tender green leaves which have green veins and petioles, and the fact that it is generally provided with a covering of soft, spreading hairs.

These two species have a range of from sea-level to 3,500 feet, and the only means of linkage between the higher and lower levels is the banks of rivers and streams. The Ourisias are all typically mountain plants, and probably the explanation of a few having been found near sea-level is that these have been washed down from higher altitudes by floods and afterwards been left stranded, some of them being successful in finding rootholds and thus becoming established. As a rule, the species are much more abundant at the higher limit of their distribution than at the lower.

O. sessilifolia is an attractive little plant of rather striking habit. The lower portion of the stem is of the creeping and rooting type with the partially distichous leaves lying flat and pressed closely to the surface of the soil. The ovate-spathulate leaves are all radical, some two inches long, densely hairy, and forming very shapely rosettes of a beautiful olive-green. The tiny flower stem, which at most barely reaches six inches in height, bears from four to eight blossoms which are of exquisite beauty. The individual flowers are quite small, three-quarters-of-an-inch in diameter, white at the margin and shading into a fine deep violet-purple at the throat. This charming little plant is fairly abundant in the southern Alps, where it inhabits moist, shady places—never in full sunlight—

at altitudes ranging from 3,000 to 5,000 feet. This little fellow likes to perch in shady places on rocks, etc., and during the months of January and February the plant-hunter who is fortunate enough to come across it must be *blasé* indeed if he is not thrilled with his find. Unfortunately, O. sessilifolia seems to be rather impatient of civilisation, and seems to prefer the seemingly uncongenial surroundings of its natural habitat to a shady nook in the rock garden.

This group of Ourisias is distinctly shade-loving, and therefore must have at least partial shade when cultivated in the garden. Like the majority of plants from high altitudes, they have developed a remarkable thirst, which can only be dissipated by fresh water. If they are planted in an open soil, with good drainage for surplus water, and are not allowed to become too dry, they are, mostly, comparatively easy of cultivation.

Of the mat-forming group, O. caespitosa (Fig. 84) is probably the best-known species. It forms broad, dense carpets of small, shining, bright green leaves which are almost one-third-of-an-inch long, fleshy and glabrous. The delicate, white flowers, which shade away to a fine golden-yellow at the throat, are borne on frail little stems which are giants if they reach four inches in height. In early spring each stalk will be laden with a beautiful burden of blossoms; sometimes so many as five flowers succeed in crowding themselves on these frail-looking stems. In their native habitat, between 3,000 and 6,000 feet, on the southern Alps, they are often very abundant, and within a short time after the winter snows have receded they are out enjoying the sunshine. Owing to their extensive altitudinal range they may be found in flower from the end of November until the end of February. If one goes in search of this charming little wilding one sees it ripening its seeds at the lower levels, while as one ascends the mountain the brownish capsules become greener and greener until ultimately one reaches within a short distance of the snows, and where the snow lay a week or two ago a white carpet of the delicate little blossoms of O. caespitosa will be found.

The closely related O. modesta, to all outward appearances seems to be a tiny edition of O. caespitosa. It is much smaller in all its parts and thrives under the same conditions as the foregoing species. Of very local distribution, it is found near sea-level on Stewart Island, which lies some twenty-five miles south of New Zealand.

O. glandulosa s a quaint little species which may be readily identified by the long-jointed hairs on the leaf margins, which give the plant quite a hoary appearance. Being a member of the patch-forming fraternity, it is in several respects somewhat close to O. caespitosa, being very similar in habit and having the same altitudinal range, although its distribution is much more localised. Although in nature it is an inhabitant of peaty soils, it will flourish when cultivated in ordinary garden soil.

The cultivation of the genus Ourisia falls under two heads. Those species which normally inhabit more or less shady places should not be planted where they will be subjected to the full force of the sun's rays, although the majority of the species are capable of withstanding, and may even enjoy, a few hours' sunlight. Probably most of the misconceptions which have arisen in the cultivation of these beautiful plants have been due to imperfect understanding of their needs.

It is of great assistance in the cultivation of garden plants if the cultivator can go back to nature and observe how and where the plant chooses to grow when beyond the influence of man's interfering hand. That is not always possible, and the next best thing is to keep on moving plants which do not seem to be happy in their surroundings. If unhealthy plants, and those which produce too much growth and refuse to produce flowers, are periodically moved to different environments, many which are ordinarily classed as "very mediocre" will, when placed in conditions similar to their normal surroundings, become fine specimens of their kind and may sometimes develop into quite beautiful subjects.

The mat-forming Ourisias inhabit bleak, upland moors, where they have to battle through all sorts of adverse conditions, and, therefore, they develop a low and compact habit to help them counteract the effect of intense isolation and biting winds; during the winter months they can rest safely covered from all harm by frost, by a heavy blanket of snow. They will thrive and even flourish in the rock garden when exposed to wind and sunshine, but they must have plenty of moisture because they hang their heads at the mere suggestion of drought.

All the New Zealand Ourisias may be propagated with remarkably little trouble. The plants lend themselves to division, which is best done in autumn, while the seeds usually germinate freely. They are not plants which are difficult of cultivation when one knows which are shade-lovers and which are not, and, therefore, they should become popular plants for the alpine garden. Although Hooker knew most of the above-mentioned species in 1864, only two of them seem to have reached the gardens of Great Britain, and even they seem to be far too rarely met with. *A. W. Anderson, Dunedin Botanic Garden, New Zealand.*

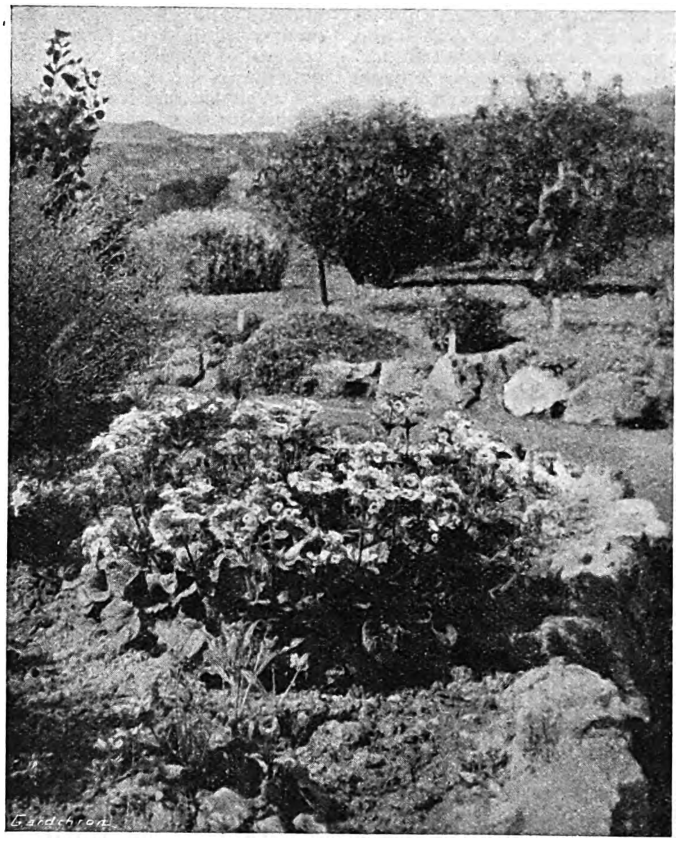

FIG. 83.—OURISIA MACROCARPA IN THE BOTANIC GARDEN, DUNEDIN.

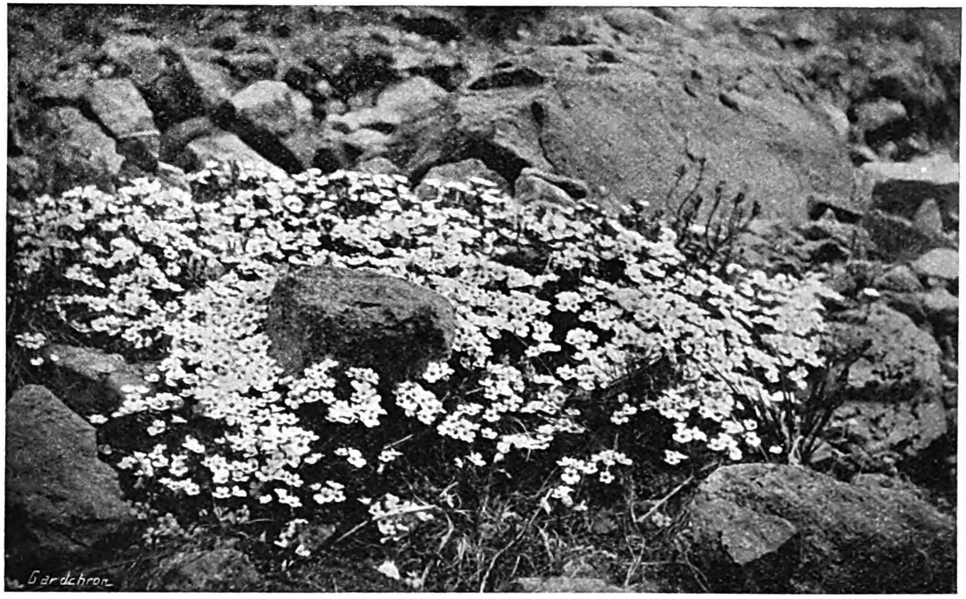

FIG. 84.—OURISIA CAESPITOSA IN ITS NATIVE HABITAT.

AN INTERNATIONAL GARDEN OF PEACE.*

When the members of the National Association of Gardeners decided to hold their 1929 Convention in Canada, they established a precedent, for never before had the Association held its Convention out of the United States. It took courage to do this, but progress is made by the application of courage and the establishing of precedents. This great international meeting is the result. It is, however, but the first result, for out of it will surely come progress to our beloved horticulture, and in the creation of friendly international relationships which will stand out as examples to the world for all time.

We are glad you came! We desire to work with you, to consummate International Plant Registration and the Patenting of Plants, but it is not of this I am authorised to speak this evening. Your worthy President, Mr. D. L. Mackintosh, has accorded me the great honour to introduce the project of an International Peace Garden. For many years I have wondered what could be done to help to maintain the goodwill which exists between our nations and, as one interested in horticulture, to bring about a better understanding and a closer co-operation between the horticultural organisations of both countries. Therefore, when at Greenwich, last October, I looked into your faces and partook of American hospitality, the feeling that we must be brought closer together was intensified. Could there be a more fitting medium to this end than an International Garden, a common meeting ground, and a great and beautiful symbol of peace and goodwill? Could any other memorial be so good as one full of life and beauty, or appeal more to the heart of mankind? How wonderfully educational would this garden be, and how helpful!

On returning to Canada, I thought what a mighty influence for good were the people who love flowers and trees and the beauty of God's great outdoors. How opposed are they to those who glorify war—hellish war, with all its horrors. They will have no dealings with these enemies of civilisation, rather their ideal is to build and uphold civilisation. Then the thought that we, the horticulturists of the United States and Canada, could show the man who speaks without love of his fellow man in his heart, that it is time for the madness to end. We will do it by example, and the example we intend to set with the permission of our Governments is to lay out a magnificent garden at a point on the International Line, a beautiful and living memorial to everlasting peace between our two nations, a thing of supreme beauty, and an inspiration to the hearts of all men; a reminder that the greatest ideal and aim that nations can have is love of their fellow men, and enduring peace on this earth. Such an example to the people of all the nations of the world will this memorial be!

The Garden of Eden is no more; God made it for man. Now man will honour God and make a garden and dedicate it to Him, and somewhere along the International Line will rise a second Eden, and the nations of the world will shed tears of joy. Every time we visit this garden, every time it is mentioned, we will be reminded of its purpose—goodwill between nations. We believe our Governments will help! We believe Great Britain and the whole British Empire will rejoice, and that will help to establish the garden, for it will be a memorial to more than a hundred years of peace between Britain and the United States. The whole world will help and rejoice.

The world is looking to North America for a vision, even although it be but the effort this Convention is putting forth. Its heart is aching for an expression of that goodwill which brings nations together, and is that for which we strive. In this meeting all nations are interested. The people will be glad that we, the horticulturists of two great nations, have arrived at a stage in our existence where we realise that although it is a big thing to bring about a national reform, it is a greater to bring about an international reform, which has for an object service to all mankind. It is such movements as these which break down the barriers of reserve and which largely offset the insidious and dangerous propaganda of those who delight not in cementing relations between nations, but in destroying, through the agency of bloody war, the economic and moral structures which our civilisation has raised.

Men who encourage war have no love for their fellow men. They are the scourge of civilisation and righteousness is foreign to them. They would tread over the dead bodies of men and the sorrows of women and children to attain their ends, and amid the ruins of the most beautiful things the ages have reared would chuckle at the monstrous thing they have wrought. Jealousy, prejudice and hatred dominate the lives of these men. Their way is that which tends to destroy the highest ideals of humanity. Thank God the majority think the other way, included among whom are the representatives of the greatest horticultural organisations on this Continent present to-night. The influence of your lives is the barrier against which hard feeling will beat itself and break as harmlessly as waves upon a rock-bound shore. It will be this influence which will help to establish the Garden of Everlasting Peace, wherein prejudice and hatred will soften and blossom, like the flowers, into love.

Thank God for your influence. You have lifted your eyes unto the hills, and have seen the wondrous beauty of the creation. You are a credit to our two great countries. You love the beauty of the universe and your neighbour as yourself. The things you work with and enjoy signify your love. Your love expresses your character. It stamps you as leaders in your communities, and as nation builders. The example of your lives may be likened to that of the lowly Nazarine who "went about doing good."

Wonderful memorials have been erected between our countries. We have the Peace Bridge between Buffalo and Fort Erie; the Ambassador Bridge between Windsor and Detroit, and other splendid projects are being considered. We, as horticulturists, desire, however, to establish an International Peace Garden, a great horticultural and botanical centre, and in which may be grown and tested all the newer originations, and which may become the international clearing station under an international committee, and the authority to recommend registration or otherwise to the Registration Bureaux of both countries.

Financing the Project.

How to finance this great project is a matter for the consideration of an International Committee, which, may it be suggested, could be organised during this Convention. We, in Canada, have thought that it would be better to state a small sum as a minimum, say 25c., so as to make it possible for practically every family in the United States and Canada to subscribe and to accept subscriptions of larger amounts from individuals and organisations inclined to give them. Thus it would really be the people's garden. A thing they help to establish they would revere. Every child in every school could contribute at least five cents to the endowment, and as the children of today will be the voters and legislators of tomorrow, the fact of having contributed to the Peace Garden would have a great influence for good in later life. They would never seek to destroy the thing they helped to create. In these and other ways an endowment of at least $5,000,000 could be raised, which, properly invested, would yield an annual revenue large enough for capital and maintenance charges.

We have approached several hundred Canadians and Americans, among them the heads of large industrial companies, and in all cases the movement has met with approval and promises of financial help. We have a considerable sum in view as a result, and which will be deposited as a nucleus of the endowment.

In my hand I hold a priceless document. It tells a story as deathless as that of the origin of the first garden. It tells that Canadians and Americans did, in the year 1929, in their love for each other, promise to subscribe to make possible the project. Their names, along with those of the millions yet to sign, will be printed in volumes and be handed down to the generations yet unborn, as the authentic historical record of the origin of the Garden of Peace.

The United States Ambassador to Canada, the Hon. William Phillips, the highest representative of the American Government; and the Governor-General of Canada, Lord Willingdon, the direct representative of the King and of Great Britain, have endorsed the project. The Prime Minister of Canada, the Hon. William Lyon Mackenzie-King, kindly sent a representative to this meeting. The Hon. George S. Henry, a Minister of the Ontario Government, is present. The Hon. John S. Martin, Minister of Agriculture of Ontario, and the Hon. William Motherwell, of the Dominion Government, are in accord with the project. What better endorsement is possible?

Mr. President, with your permission, I will read the letters of Mr. Phillips and Lord Willingdon.

Legation of the United States
of America, Ottawa, Canada.
July 18, 1929.

Henry J. Moore, Esquire,
Chairman, Canadian Committee,
National Association of Gardeners,
Box 61, Islington, Ontario.

Dear Mr. Moore,

I regret exceedingly that owing to my absence from Canada during the month of August, I cannot have the pleasure of attending the Convention of the National Association of Gardeners. Especially do I regret that I shall not be able to be with you on "International Night" when it seems possible that reference may be made to the proposed International Peace Garden to be situated somewhere along the border between Canada and the United States. Such a project appeals to me immensely, and I should like to identify myself wholeheartedly with it. I can think of no finer memorial to the lasting friendship of our two countries than a garden or park where the beauties of nature are revealed and augmented by the skill of Canadian and American horticulturists.

I wish to express to the great concourse of gardeners assembled my cordial regards and best wishes for the success of their Convention, and my fervent hope that their inspiring ideal will come to pass and be an historic shrine for pilgrims from both countries.

Sincerely yours,
(Sgd.) William Phillips.

La Citadelle,
Quebec.
July 19, 1929.

Any scheme which has for its purpose the promotion of peace, of friendship and co-operation between the people of our two nations will always have my cordial approval.

I therefore send my greetings to all members of the Convention of Canadian and American Horticulturists which is to meet in Toronto next month, and trust that the result of their discussions may bring about a further development of the charming idea of starting a Peace Garden somewhere on the boundary between our two countries.

(Sgd.) Willingdon.

To this garden all mankind will come, for all eyes will long to see its beauty. Every heart will yearn to visit it, and the question which will greet the homecomer of every nation will be:—"Did you see the International Peace Garden?" and the reply, "Yes, it is the greatest and most beautiful memorial ever conceived by friendly nations; beautiful because of the love of one nation for another, and because the things it contains all live and are God's most wonderful expression of His love for mankind. The greatest and most beautiful memorial because, in the garden, love has removed every barrier. It is truly a land without a line."

---

* An address delivered by Mr. H. J. Moore at the Convention of the National Association of Gardeners of the United States, at Toronto, Canada, August 7.

Mr. H. J. Moore, an old Kewite, is Forester of Provincial Highways and Lecturer in Horticulture in the Province of Ontario. His portrait and an account of his work appeared n *The Gardeners' Chronicle* of July 3, 1926.

To the ladies and gentlemen from the United States, may I, in the following lines, extend the friendship of Canada. It is the spirit of the garden, and is entitled:

A Land Without a Line.

You came to the land of the Maple Leaf
And we met you with a smile,
We took your hands in a friendly grasp
And hoped you'd stay awhile.
Though you live 'neath the Stars and Stripes
And we 'neath the Union Jack,
We speak the same old mother tongue
Uncle Sam and Jack Canack.

Between us runs three thousand miles,
A line from coast to coast,
Where never a fort and never a gun
Is seen; we proudly boast
No bayonet with its murderous steel
No sentry anywhere,
And we live in peace on either side
As though no line were there.

Side by side for a hundred years,
May it be a thousand more!
With never a word to cause us grief
Nor any to make us sore.
We have lived and still the Union Jack
And Stars and Stripes unfurled
Have flown together on the line
The wonder of all the world.

Please God 'till earth's last Sun shall set
And earth's last tears be shed,
May we two nations still be friends
When to heaven Thou call'st the dead.
Until on that eternal morn
As its glorious sun shall shine
Thy nations meet around Thy throne
In a land without a line.

THE GENUS PRIMULA.

(Continued from p. 152).

PSEUDOMALACOIDES (L. B. Stewart). False Fairy P.
(Malacoides).

This perennial is a sub-species of P. malacoides. The rootstock produces several sparsely-leaved rosettes of rather fleshy foliage with broadly oblong-elliptic or elliptic, blunt blades about one-and-a-half inch long, usually abruptly contracted into a distinct, fleshy, downy stalk about two inches long; margins lobed and furnished with sharp, saw-like teeth terminating in a horny tip; both surfaces clothed with short, white hairs, underside coated with white meal. Flower stems numerous, slender, decumbent, twelve to sixteen inches long, sparsely coated with white meal and bearing several superposed umbels of numerous pale lilac, yellow-eyed blossoms. Corolla about half-an-inch across; segments flat, egg-shaped, deeply notched and slightly recurved; tube cylindrical, about a quarter-of-an-inch long, white at the base, yellow towards the mouth, sparsely mealy outside. Introduced in 1908. *Gard. Chron.* 1908, Vol. XLIV, p. 396, Figs. 164 and 165, under P. malacoides.

This plant is a native of Yunnan, western China.

Culture: As for P. Forbesii.

PSEUDOPETIOLARIS (Pax et K. Hoffm.). False Petiolate P.
(Petiolaris-Sonchifolia).

A dwarf, non-mealy, moderately hairy perennial with a tuft or rosette of membranous leaves, three-quarters- to one-and-a-half-inch long, including the stalk, with diamond-shaped-oblong, pointed blades half-an-inch to one-and-a-quarter-inch long, and five-eighths-of-an-inch to one inch wide, gradually tapering to a winged stalk; margins furnished with irregular teeth as though gnawed by insects. Flower stem obsolete or up to a quarter-of-an-inch long, bearing several blossoms on thread-like stalks about five-eighths-of-an-inch long. Corolla about half-an-inch long and three-eighths-of-an-inch across, with heart-shaped, notched lobes sometimes edged with small, rounded lobes or coarse teeth; tube cylindrical below, dilated and funnel-shaped at the throat, about a quarter-of-an-inch long, exceeding the calyx in length. Not in cultivation.

The plant was discovered near Matturu (Missurie ?) in the Himalayas, but the colour of its blossoms and the conditions under which it grows have not been recorded.

Culture: As for P. petiolaris would probably prove suitable.

PSEUDOSIKKIMENSIS (Forrest). False Sikkim Cowslip.
(Sikkimensis).

A very beautiful sub-species of P. sikkimensis, (Hook.). It is a deciduous perennial with a tuft of thin, somewhat flaccid, oblong-spathulate, blunt leaves, tapering to a broadly winged stalk, in all two to eight inches long; margins edged with small, sharp teeth; both surfaces more or less smooth. Flower stem five to eighteen inches tall, bearing a terminal umbel of many nodding, fragrant, bright canary-yellow blossoms on down-curved stalks. Corolla concave, from five-eighths-of-an-inch to nearly one inch across, divided into five rounded, notched segments; tube cylindrical below, funnel-shaped above, longer than the calyx. Flowers in June and July. In cultivation in 1913. *The Garden*, June 14, 1913.

Grows in damp, stony, alpine meadows and in crevices in limestone cliffs, on the Lichiang range, in Yunnan, western China, at 11,000 to 15,000 feet above sea-level.

Culture: Good calcareous loam, in an open spot well supplied with underground moisture when the plant is in growth, should suit it.

PUDIBUNDA (W. W. Sm.). Tibetian Cowslip.
(Sikkimensis).

This plant is a sub-species of P. sikkimensis (Hook. f.); it produces a large rosette of smooth, non-mealy leaves with narrow, obovate-spathulate blades two-and-a-half to three-and-a-half inches long, rounded or blunt at the tip, generally tapering at the base to a wedge-shaped stalk from two to three inches long; margins edged with sharp, saw-like teeth; upper surface conspicuously veined. Flower stem six to twelve inches tall, slightly mealy among the flowers, bearing an umbel of three to four somewhat nodding, pale yellow, fragrant blossoms, on slender, curved stalks under half-an-inch in length, covered with meal. Corolla funnel-shaped, concave, under half-an-inch across, with rounded, notched lobes; tube cylindrical, about half-an-inch long, slightly longer than the calyx. Flowers in July.

Grows in damp, open alpine situations near streams on the mountains of south-eastern Tibet (where it reaches an elevation of 15,000 feet above sea-level), north-western Yunnan, western Szechuan and the Sikkim Himalayas, near the Tibetian border, at nearly 14,000 feet.

Culture: Fibrous peat and sandy loam, abundantly supplied with water when the plant is in growth, with drier conditions when it goes to rest, are the conditions indicated.

PULCHELLA (Franch.). Pretty P.
(Nivales).

A very delightful perennial species with a rosette of rather thin leaves from two to four inches long, with narrowly lanceolate, pointed or blunt blades tapering to a narrow stalk; margins revolute and finely toothed; upper surface more or less smooth, underside coated with yellow meal. Flower stem six to twelve inches tall, erect, bearing a many-flowered umbel of rich violet, purplish-blue or mauve blossoms with a yellow or orange eye. Corolla about three-quarters-of-an-inch long and three-quarters-of-an-inch across, divided into five heart-shaped, notched or entire lobes; tube cylindrical, about twice as long as the calyx, with a little, ball-like tuft of white hairs in the throat. Flowers in June. Introduced in 1908.

Grows in dry, stony, calcareous mountain pastures, frequently in shade, in the Tali region of Yunnan, at about 7,000 feet above sea-level; also in south-eastern Tibet at Tongkyuk, at 10,000 to 11,000 feet, on shady banks of loose soil, and also in dry, stony meadows on the mountains around Muli, in south-western Szechuan, at 11,000 to 12,000 feet.

Culture: Good, gritty, calcareous loam in a well-drained, half-shady spot well supplied with water during the growing season, with protection from wet in winter, should suit it.

PULCHELLOIDES (F. K. Ward). Orange-throated P.
(Nivales).

A beautiful, perennial species with a tuft of blunt, linear-lance-shaped, somewhat thick leaves, about one-and-a-half inch long and three-eighths-of-an-inch broad, narrowed into an obscure stalk; margins slightly revolute and furnished with broad, regular, triangular teeth; upper surface emerald-green, underside densely covered with yellow meal. Flower stem six to fifteen inches tall, often sprinkled with yellow meal and bearing a terminal umbel of about eight pale violet, purplish-blue or mauve, fragrant blossoms with a yellow or orange throat, on rigid stalks about one inch long, sparsely coated with yellow meal. Corolla flat, about three-quarters-of-an-inch across, divided into five broadly heart-shaped, or oblong-egg-shaped, bilobed segments, mealy on the outer surface; tube cylindrical, slightly longer than the calyx, with a ten-lobed ring in the mouth. Flowers from June to August. Introduced in 1911.

Grows near Atuntsu, in north-western Yunnan, at about 13,000 feet above sea-level, also in south-eastern Tibet, at Kong Peri, and on Nyima La, under the shade of dwarf Oaks, also on the ledges of cliffs and on dry rocky slopes on the mountains east of Yungning, in south-western Szechuan.

Culture: As for P. pulchella.

PULCHRA (Watt). Dainty P.
(Petiolaris-Tongolensis).

A beautiful, dwarf, perennial species with a tuft of nearly smooth, non-mealy leaves from one to one-and-a-half inch long, with oblong or oval-oblong, undulate, pointed blades, heart-shaped at the base, abruptly contracted into a stalk from one to one-and-a-half inch long sheathing the rootstock; upper surface rich green, underside glaucous. Flower stem about one-and-a-half inch tall, bearing an umbel of two to ten purple blossoms. Corolla about one inch across, with broadly heart-shaped, cleft, seemingly more or less toothed lobes; tube longer than the calyx, funnel-shaped, with an obscure ring in the throat.

Grows near Jongri, in the Lachen valley, in the Sikkim Himalayas, at 12,000 to 13,000 feet above sea-level.

Culture: Grow it in good fibrous loam in a damp, open spot, well-drained in winter.

PULVERULENTA (Duthie). Dusty P.
(Candelabra).

The type of this well-known deciduous, perennial species has a short, stout rootstock and tufts of membranous, pulverulent leaves from six to eighteen inches long, with obovate or oblanceolate, blunt blades tapering to a long, winged stalk; margins edged with irregular teeth and at times obscurely lobed. Flower stem from eighteen to forty inches tall, mealy, bearing numerous superposed umbels of many deep rosy-purple or violet blossoms with an orange-brown eye; the spreading, mealy stalks are half-an-inch or more long. Corolla about one inch across, deeply divided into five broadly heart-shaped, notched lobes; tube cylindrical, longer than the calyx, with a ring in the throat. Flowers from May to August. Illustrated in *Journal* Roy. Hort. Soc., Vol. XXXIX, 1913. Introduced in 1905.

This beautiful plant, of which there are white, pink, rose and orange-coloured forms or hybrids in cultivation, grows in marshes on the mountains of western Szechuan, at 8,000 to 10,000 feet above sea-level.

Culture: It delights in good, rich loam in a damp, open or half-shady position, and is seen at its best on the banks of a stream or pond. *A. W. Darnell.*

(To be continued).

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, Ante pp. 112-118.)
(*Continued from p.* 154.)

CHESHIRE.—All fruit trees flowered profusely. Apples set well. The foliage on all the trees, on the whole, is clean. Strawberries were a good crop with healthy foliage, but owing to such dry weather, the fruits were soon over. Gooseberries, and Black and Red Currants have carried heavy, clean crops. Raspberries are very promising. Morello Cherries are a good average crop, but sweet Cherries never do well here. Plums are also poor. They set well, but owing to the dry weather they failed to stone. Apples are a splendid crop, the best varieties being Tylers' Kernel, Bramley's Seedling, Sandringham, Golden Winter Pearmain, Beauty of Bath, Emperor Alexander, Irish Peach, Warner's King, Frogmore Selected, Ecklinville, Mr. Gladstone, Beauty of Kent, Cox's Orange Pippin, King of the Pippins, James Grieve and Schoolmaster. The best Pears are Beurré Capiaumont, Catillac, Marie Louise d'Uccle, Pitmaston Duchess, Emile d'Heyst, Beurré Diel, Conference and Louise Bonne of Jersey. The weather, at the time of writing, is very dry and hot. The soil is a medium loam, on a subsoil of sand. *James R. Allan, Tirley Garth Gardens, Tarporley.*

—— It is many years since we experienced frosts of such severity as those that occurred in February. The cold north-east winds which prevailed after the frosts were over did much damage to fruit trees in flower; on April 26, ten degrees of frost were registered. Plums and Cherries suffered most. The most promising Apples are Beauty of Bath, Irish Peach, James Grieve, King of the Pippins, Wealthy, Dumelow's Seedling, Ecklinville, Keswick Codlin and Lane's Prince Albert, while Pears which are carrying good crops include Beurré Hardy, Beurré Superfin, Clapp's Favourite, Jargonelle, Marie Louise and Louise Bonne of Jersey. Small fruits have carried record crops, especially Black Currants and Gooseberries. The soil here is a sandy loam, over a stiff clay subsoil. *H. J. Thomas, Birtles Hall Gardens, Chelford.*

—— The majority of the Apple trees here are growing in a mixture of light clay and sand, with a sub-strata of sandstone. On the west side we have the Welsh hills, and on the south-east the Cheshire hills. The position is, therefore, rather exposed. The Apple crop is a good average one; the trees are clean, and after the recent rain the fruits are swelling well. Some of the flowers were damaged by frosts, in a very early stage, but the remainder opened clean and strong. The Strawberry crops, while very disappointing in some parts near here, in others were better than they have been for a number of years, and this in spite of the severe frost, and keen winds which brought every leaf down to the ground in the spring. Plums are a failure, owing to frost, but there was plenty of bloom. While Cheshire is not a Pear county, there appears to be quite an average crop. We spray our Strawberry plants regularly from an early stage, and are getting much improved crops thereby. *N. F. Barnes, Eaton Gardens, Chester.*

DERBYSHIRE.—Apples are a good average crop, but Pears suffered severely from frost when in flower. The recent rain will greatly benefit all hardy fruits after the long drought. *William Parks, Whittington Hall Gardens, Chesterfield.*

—— The general condition of the fruit crops here is, in most cases, satisfactory, although the Plum crop is more or less a failure, considering the number of trees here of a bearing age. This, however, is more than counterbalanced by the returns of small fruits, Black, Red and White Currants being overladen with fruits which, despite the drought, have been of first class size and of very good quality. Raspberries, also, have done well, both the red and yellow-fruited varieties yielding abundantly. Taking all points into consideration, the returns of Apples are very good, the best varieties being Worcester Pearmain, Keswick Codlin and Bramley's Seedling. Cox's Orange Pippin seems to do well here also. The soil in these gardens is of a heavy loam. *George H. Lightfoot, Smalley Hall Gardens, Smalley, nr. Derby.*

HERTFORDSHIRE.—The fruit crops in these gardens are below the average in some respects. Apples are very poor, as these suffered considerably through cold north-east winds and late frosts. We experienced twelve degrees on May 1 and six degrees on May 2. Pear crops are about average; Strawberries, Gooseberries and Black Currants are average, but Red Currants poor, while Plums also are very much under the average. The soil here is on the clay side, and in early spring very cold. *Wm. Jas. Penton, The Node Gardens, Welwyn.*

—— The hardy fruit crops in this district are quite up to the standard, in spite of the dry weather. Trees are very clean and free from aphis and are making quite good growth, Apples and Pears especially so. The bush fruits also are looking remarkably well and carrying crops above the average. Raspberries also are bearing very good crops. The soil here is a heavy loam and all fruits do very well in it when once they become established. Old orchard trees are bearing crops much above the average, such varieties of Apples as Warner's King, Blenheim Pippin and Dumelow's Seedling being exceptionally good. *William Stephenson, Hyde Hall Gardens, Sawbridgeworth.*

—— The fruit crops generally are quite disappointing, for although there was a generous amount of bloom, much of it failed to set, the frosts and generally adverse weather conditions doubtless being responsible. Blenheim Pippin Apples are almost a complete failure, but Lane's Prince Albert is carrying a good crop. Gooseberries, Currants and Raspberries have borne heavy crops of fruits. The soil is a good marly loam, overlying a bed of gravel, so that the effects of drought are soon felt. *E. F. Hazelton, Laurel House, Cravells Road, Harpenden.*

—— The fruit crops in these gardens are, on the whole, very good. Apples on young trees have had to be severely thinned, and standard trees, in most instances, are carrying very good crops. Pears are fruiting well, the fruits of some varieties having had to be thinned. Gooseberries, Black and Red Currants, and Raspberries are all bearing excellent crops, the last-named having been well supplied with water and a good mulch. Strawberries have been excellent both with regard to quantity and quality of the fruits. Peaches and Cherries are good but Damsons are scarce. *T. Pateman, Brocket Hall Gardens, Hatfield.*

—— The hardy fruit crops this year are not up to standard. Plums set well, but 22° of frost on April 14 did a great deal of harm. Plum trees on a north wall, being late to blossom, set their fruits well and are now carrying good crops. Apples are variable, but bush fruits, in general, have carried exceptionally heavy crops. *Richard Staward, Ware Park Gardens, Ware.*

—— The fruit crops here are not very satisfactory. Apples, especially, suffered from the prolonged drought, and many of the fruits have fallen. The fruits are much smaller than is usual at this time of the year. Pears are not an average crop, but the trees have not suffered so badly through lack of moisture as the Apples, and the fruits will be better than last year. Plums are very scarce owing to severe frosts when in blossom and after setting. Peaches and Nectarines are a light crop, but the fruits are good in quality; the trees are healthy and growing vigorously. Strawberries were almost a failure. Raspberries are a good crop, but the fruits are lacking in size and flavour. Gooseberries were of good quality and plentiful. *George H. Hill, Caldecote House Gardens, Bushey Heath, nr. Watford.*

(*To be continued*).

HOME CORRESPONDENCE.

Two good Day Lilies.—At the R.H.S. meeting on July 30, Mr. Amos Perry showed two excellent Day Lilies of his own raising. Hemerocallis George Yeld has "large open flowers nearly six inches across, outer petals rich orange, inner petals flushed and mottled orange-scarlet." This very handsome plant was recommended for trial at Wisley. The other, Margaret Perry, had already obtained the A.M. I should describe it as a brighter and more refined H. fulva. I have grown them now for two years and can strongly recommend them. *G. Yeld, Orleton, Gerrard's Cross.*

Apple Tree Stem Gnawed by Mice.—The following may interest your readers. We have, growing in our orchard here, an Apple tree of the variety Lord Grosvenor, the stem of which is about four inches in diameter at one foot from the ground. During the severe frost in the early part of the year mice attacked the tree and stripped off every particle of bark for about nine inches from the ground, making a complete ring. I confidently predicted the death of the tree, but as far as I can see, the stripping has not made the slightest difference to it. The leading branches have made from nine inches to twelve inches of growth, and the tree is carrying a bumper crop of fruits. *A. Howell, Park Hatch Gardens, Godalming.*

Best Dessert Gooseberries.—I submit a list of the best dessert Gooseberries of my experience, in the four recognised colours, in the hope that someone may suggest some better ones, or at least others whose merits should not be overlooked in the multiplicity of large berries for exhibition, for commerce, or unusually large ones designated Lancashire prize varieties. Among red varieties, I would place Red Champagne, Ironmonger, and Red Warrington (much used for making jam); yellow, Golden Gem, Langley Beauty, Yellowsmith, Yellow Warrington; green; Early Green Hairy, Glenton Green, Lancer, Pitmaston Green Gage; white, White Champagne, and Langley Gage. Of the above the Red Warrington can be grown to a good size, also Yellow Warrington and Golden Gem. Glenton Green is of medium size but is somewhat given to fungus diseases in the south, so that Early Green Hairy could take its place. Glenton Green has been known in England for sixty years or more. Yellowsmith lacks the tough skin and dense downiness of Whitesmith. *J. F.*

Rosa gigantea.—It may interest some readers to know that the name of this Rose, given by Collet and Hemsley, has undergone a new combination in America. Mr. Rehder and Mr. E. H. Wilson have concluded that R. gigantea is only a variety of the climbing Tea Rose. They have resuscitated R. odorata, Sweet, for this, so that the new combination is Rosa odorata var. gigantea. They describe it as climbing to a height of ten metres, that is, over thirty feet. The creamy-white flowers are four to six inches in diameter. The native countries are given as south-west China and Burma, and the date of introduction is 1889. R. odorata var. erubescens, Rehd. and Wils. is also described as a form of the preceding variety, with blush or pale pink flowers, often smaller, and native to western China. Curiously enough they do not know the date of introduction of the coloured variety, but add the note: "This form or the preceding variety is probably the phylogenetic type of the Tea Rose."

Viola cornuta.—The two varieties of the above, namely, V. cornuta var. Lavender Gem, and V. cornuta var. White Gem, shown at the meeting of the Royal Horticultural Society, on August 13 last, by Messrs. Watkins and Simpson, Ltd., and selected for trial at Wisley, might well have been accorded Awards of Merit, if only to emphasise the value of this truly perennial species and encourage the raising of even better varieties. Sometime in the sixties of last century, the late Mr. John Wills, of South Kensington, showed how valuable the old V. cornuta var. Perfection was for bedding purposes. This immediately became so popular that it found its way to the north of Britain in the beginning of the seventies, and was extensively cultivated as edgings for walks, for beds, and in ribbon borders, during the vogue for that style of flower gardening. At the end of the season the plants were more or less cut back, lifted and heeled in thickly in any open border. There they remained until they were required again for the above purposes, and by that time they were flowering freely. This showed their extreme hardiness, while they flowered freely until the end of the season. Three varieties came under my care, including the above, the other two being Enchantress and Magnifica. Both these had larger flowers than Perfection, which was about the size of V. cornuta var. Lavender Gem, but was a darker and more decided blue. *J. F.*

Lilium auratum.—The instance mentioned by *W. A.* (p. 126) of forty-eight flowers on a stem of this Lily is not the highest number known; as a stem—also fasciated—produced 110 flowers at Linton Park, Maidstone, in 1873; the late Mr. John Robson was gardener there at that time. He took great interest in the Maidstone Gardeners' Society, of which he was President, and exhibited the stem at one of its meetings. The plant was growing among Rhododendrons in a peat bed, and in a warm position, and had been there for several years. Some very fine stems from Scotland were exhibited at one of the autumn shows at Holland Park a few years ago, but I have no record of the number of flowers. It is a pity this fine Lily is so short-lived under outdoor cultivation; there are some fine stems with twenty-four flowers apiece at Kew at the present time in a Rhododendron bed; probably they are lifted every year. Kew is fortunate in having a good quantity of the variety platyphyllum, which is more vigorous than the ordinary form. *W. H. Divers, V.M.H.*

FRUIT GARDEN.

AUTUMN PRUNING OF FRUIT TREES.

Although the pruning tools are little used at this season of the year, there is good use to be made of them in the fruit garden just now. Most people cut out the old canes from Raspberries and Loganberries so soon as fruiting is over, and even Black Currants often receive timely attention, but, beyond this, pruning is considered to be essentially a winter job. It is evident that some pruning must be left until the dormant season, but that cutting out which may be more definitely be called thinning, can, with great advantage, be undertaken at once. Bright, sunny weather is often enjoyed in autumn, and nothing but good can accrue from allowing the sunshine full access to the wood which is to be retained for fruiting.

Red Currants may have all the growths but the terminals shortened considerably. Any branches needing removal from Gooseberry bushes may be cut out. Old bushes seem to need annual treatment in the removal of branches which touch the ground, and others which close the centre of the bush. The final winter pruning of the bush fruits will then consist merely of spurring back and tipping.

Among the Apple trees, branch thinning may be carried out where no crop is on the trees. It is surprising how different a tree appears now from what it does when leafless. One may wander around in winter with pruning saw and find little use for it, but, at the present time, it is easy to detect overcrowding which should have been prevented. One may state that it is almost impossible to thin out a tree satisfactorily when it is dormant. Many trees of both Apples and Pears which have reached considerable age are crowded with spurs which give abundant flowers and few fruits. The removal of one half or even two-thirds of the spurs often results in cropping. This work is rather tedious and not very pleasant on a cold, wintry day, and may be undertaken under more comfortable conditions now. *E. Brown, Hillside, Doddington, Sittingbourne.*

SOCIETIES.

ABERDEEN HORTICULTURAL.

August 15, 16 and 17.—The Royal Horticultural Society of Aberdeen held a fine show on these dates in the beautiful public park at Hazlehead, again kindly lent by the Aberdeen Town Council. The show must be reckoned one of the best held under the auspices of the Society in its 105 years' history. Additional interest was added to the occasion by the fact that this year the Scottish National Sweet Pea, Rose and Carnation Society held its provincial show in conjunction with the event. Unfortunately, the weather was not too kind on the second and third days. The Marchioness of Aberdeen and Temair gave the show a happy send-off, in the course of which she stressed the importance and delight to be derived from window gardens. Sir Thomas Jaffrey, Chairman, and Mr. W. B. Clark, Superintendent of Aberdeen's public parks, Vice-Chairman, were at their posts, while Mr. J. B. Rennett, Secretary, as is his wont, had all arrangements carefully carried out. The entries numbered 1,192, compared with 1,140 last year, and despite the strange weather experienced in the north this year, the quality of the exhibits was well up to standard.

Pot Plants.

These were very good generally. Mrs. W. A. Leith, Brackenhill, Aberdeenshire (gr. Mr. Alex. Gordon), had a notable win for the best group of pot plants arranged for effect on a space twelve feet by nine feet; second and third places were awarded the entries from the gardens of Morkeu and Balmedie. The Brackenhill entry was far and away the best, comprising finely-grown, healthy, beautifully coloured plants. For four specimen plants and Ferns, the honours went to Captain E. F. Lumsden, of Balmedie (gr. Mr. William Morrison); Mr. A. E. Benzie, Morkeu (gr. Mr. William Henderson) was first in two classes for Pelargoniums. Fuchsias, of which we hear so little nowadays, were finely shown from Brackenhill Gardens. Begonias, single and double, were outstanding, the leading places being taken by Sir Thomas Jaffrey, Edgehill (gr. Mr. James Cook), with exquisite specimens. The honours for the best four plants for dinner table decoration also went to Edgehill. Petunias and Gloxinias were best represented from Brackenhill Gardens.

Sweet Peas.

As is always the case nowadays, this section formed a great attraction and the competition was very keen. There was a stiff tussle between Annie, Lady Cowdray, Dunecht, Aberdeenshire (gr. Mr. William Smith), and Mr. John A. Grigor, Woodlands, Banff, for the best dozen vases of Sweet Peas, but the Viscountess won. Her entry included finely-grown and richly-coloured specimens of What Joy, Mrs. A. Searles, Grenadier, Sunkist, Jessie, Pinkie, Lassie, Magnet and Powerscourt. Mr. Grigor, however, with his fine blooms of Youth, Wizard, Hebe, Chieftain, Susan, Purple Monarch, Magnet and Grenadier, had little cause to be discouraged. Mr. Grigor also led for lavenders, with Powerscourt; pinks, with Pinkie; and purples, with Olympia.

Mr. A. S. Dow, Darnaway Castle, Forres, also did remarkably well in this section, being first for a vase blended for effect; for whites, with Victor; and for crimsons, with The Prince. Captain J. W. Guy Innes, R.N., Kirkville House, Aberdeenshire (gr. Mr. T. C. Gardiner), led for creams, with lovely specimens of What Joy. Mr. John D. Paton, Grandhome House, Aberdeenshire (gr. Mr. Cyril Cox), had a fine win for the best three vases (distinct), with fine blooms of Mermaid, Mrs. A. Searles and Olympia.

Cut Flowers.

Outstanding in quality and wealth of colour, this section is always a favourite at Aberdeen. For the best twelve ten-inch vases of hardy herbaceous flowers (distinct), Mr. Cox, of Inchmarlo, Kincardineshire (gr. Mr. Alex. Duncan), led finely, followed closely by Lord Sempill, Fintray House, Aberdeenshire (gr. Mr. W. D. Anderson). Chrysanthemums were best shown from the gardens of Stoneywood House, Aberdeenshire (gr. Mr. G. Meldrum); Grandhome House, and Fintray House. Mr. D. Whitelaw, Laurencekirk, was first for Gladioli. Decorative Roses were well shown, the honours being shared by the entries from the gardens of Grandhome House, Stoneywood House and Brackenhill. Balmedie Gardens sent the finest three vases of Roses (distinct). Dahlias formed a very fine class, the leading honours for Collerette, Cactus and Single Dahlias all going to Grandhome entries. Stocks were well shown, the Inchmarlo exhibits taking pride of place. For twelve vases, distinct varieties, of cut flowers, the Darnaway Castle entry left little to be desired. Carnations and/or Picotees made a pleasing display, Balmedie House leading. The Zonale Pelargoniums from Dunecht were well shown, as also were the eighteen Rose blooms from the same gardens. Begonias made a capital display; Sir Thomas Jaffrey, Edgehill, had all his own way here for both single and double varieties. They formed a really fine feature of the section. He also won leading places for sprays and buttonhole bouquets.

Fruits.

The weather this season has not been just all one would like, but this did not prevent a wonderfully good display. To Fintray House went the leading place for the best collection of hardy fruit, which included fine specimens of Diamond and Victoria Plums; Bramble (cultivated), Moor Park Apricot and Worcester Pearmain Apple. The Strawberries from Grandhome Gardens were fine specimens, but, unfortunately, this fruit has been far from a success from a commercial point of view in Scotland this year. The best specimens included Sir Joseph Paxton and Tardive de Leopold. Blackberries, Raspberries, Gooseberries (yellow and green), and Red and Black Currants, made a good display, the outstanding entries coming from the gardens of Kirkville House, Brackenhill, Inchmarlo, Stoneywood House, Linton House (gr. Mr. A. Ferguson), R. Duncan, Old Montrose, and Mr. J. H. Gait, Oddjest, Stonehaven, Kincardineshire.

The entries of Grapes were more numerous than has been the case at Aberdeen for some years. Lord Sempill and Sir James Burnett, Bart., of Leys, Crathes Castle (gr. Mr. William Grant), shared the leading honours with nicely-grown bunches. The best dessert and baking Apples came from Annie, Lady Cowdray, with finely grown samples of Lord Rosebery and Rev. W. Wills, and she also provided the best Peaches. From Balmedie Gardens came the best Melons, Nectarines, Plums and other Pears. Jargonelle Pears were best shown from Darnaway Castle.

Vegetables.

The " north-east neuk " of Scotland has always been famous for the fine quality of vegetables grown there. There was no exception to the usual rule this year, some remarkably fine, shapely, and clean-grown produce being forwarded. For the best collection of vegetables arranged on a table space four feet by three feet, and consisting of eleven kinds, viz., Pea, Cabbage, Cauliflower, Potato, Turnip, Carrot, Onion, Parsley, Beetroot, Celery and Tomato, the entry from Colonel Blair Imrie, Lunan House, Arbroath (gr. Mr. R. Harper), right worthily carried off the premier honours. It was a remarkably fine exhibit, and reflected the highest credit on all concerned. Colonel Blair Imrie also led for Cucumbers and Onions.

The other leading awards went to Stoneywood House, for Tomatos, Leeks, Celery and Parsnips. Edgehill House sent the best basket of salads, Carrots (stump-rooted) and Turnips (yellow); Kirkville House provided the leading Carrots and Cauliflowers; Colonel Stewart, Banchory House, Kincardineshire (gr. Mr. R. McQueen), had the best Peas and Beetroot (long), the best globe variety coming from Linton House. Crathes Castle led for Broad Beans, and Darnaway Castle for French Beans. The vegetable Marrows from Grandhome House were easily the best.

Potatos have always a special section at

Aberdeen, as northern growers take a great pride in this valuable tuber. For the best collection of six varieties, the Stoneywood House entry was first; and for a collection of four varieties the premier honours went to Sir **Thomas Jaffrey**. He showed also the best round, white (Arran Comrade). Inchmarlo Gardens had the best round, coloured (Climax). Mrs. **Wood**, Camphill, Aberdeenshire (gr. Mr. Charles Murray) with Duke of York, led for kidney-shaped, white, and Stoneywood House led for kidney-shaped, coloured, with Exhibition Kidney.

The model gardens were also much admired, and the wild flowers sent in by boys and girls under fifteen years of age formed a pleasing feature.

Nurserymen and Florists.

The leading feature in this section was the fine Roses exhibited by Messrs. **Adam and Craigmile**, Aberdeen, and for which the firm was awarded the Silver Challenge Cup. Their winning entry comprised superb specimens of the finest sorts now in commerce.

Messrs. **Allwood Bros.** had an exhibit of a new race of Dianthus, for rockeries, in which were fine specimens of Titania, Oberon, Tinkabell, Puck and Ariel. They also showed the new Carnation (1930 novelty) Peter, and Molly, Roger and Barbara.

Non-Competitive Displays.

An outstanding feature of the show was the fine displays made for exhibition only by leading nurserymen and florists. Space will not permit a detailed account of these. The firms deservedly worthy of mention were Messrs. **Allwood Bros.**, Messrs. **Ben. Reid and Co.**, Messrs. **Knowles and Sons**, and Messrs. **W. Smith and Son**, of Aberdeen.

Amateur Section.

Some capital produce was shown in the various classes in this section. The Silver-gilt Medal awarded by *The Gardeners' Chronicle* for the best amateur exhibit was worthily won by Mrs. L. **Harper**, Fernbank, Insch, Aberdeenshire, for six vases of Sweet Peas. This lady was also first for the best collection of vegetables with an entry that would have done credit to any show. Altogether, the amateurs did splendidly, and none were more hearty in their admiration and congratulations than the experts and professional men who understood the care and attention that must have been bestowed before such fine results could have been produced.

SHROPSHIRE HORTICULTURAL.

August 21 and 22.—On these dates the Shropshire Horticultural Society celebrated its fifty-fifth year of useful existence by holding a wonderfully fine exhibition in the famous Quarry, at Shrewsbury. For half-a-century or so, the Shrewsbury Floral Fete had few, if any, serious competitors in the English provinces, and it was the desire of every ambitious young gardener to attend the show, if only once, because outside London there was nothing to compare with it. In recent years, however, the great Salopean Floral Festival has not occupied the solo position it held for so long a period, but, fortunately, the small amount of serious competition the show has experienced has only served to enhance its reputation and increase its brilliance, while now, as ever, the "young gardener" makes the pilgrimage to the picturesque old town of Shrewsbury, to add to his knowledge and broaden his outlook. But, nowadays, he will find not only many like-minded young fellows of his own age there, besides the many veteran exhibitors and representatives of well-known seed and nursery firms, but he will find in the crowd many other people from many other countries, for there are usually visitors from Holland and Germany, India and the United States, as well as from Scotland and Ireland, while the tone of their voices will betray the many who come across the Severn from "Gallant Little Wales."

Mr. Ward, the Superintendent of the Shrewsbury Parks, has this year provided one of his very best floral displays in The Dingle—that pretty hollow endowed with a large rock garden and a brilliant flower garden, set amid the trees that are so fine a feature of the Severn-bordered Quarry.

The Schedule for 1929 included one-hundred-and-seventy-eight classes, and the prizes offered amounted to about £1,550, in addition to Challenge Cups, trophies and Medals, while no fewer than three special trophies—real works of art—together with thirty medals, were at the disposal of the judges for award to non-competitive exhibits, which, as a whole, were never finer in quality than on this occasion. The artistically-beautiful, brilliantly-coloured display of finely-grown vegetables from the Hon. **Vicary Gibbs**; the splendid array of vegetables from Messrs. **Sutton and Sons**; the fruit trees in pots from the **King's Acre Nurseries**; the rock and water garden from Messrs. **Bakers**; the Dahlias from Messrs. **Dickson and Robinson**; the Roses from Mr. T. **Robinson**, and from Messrs. **Alex. Dickson and Sons**, were a few exhibits of outstanding excellence and attractiveness.

Throughout the competitive section the exhibits were generally of high quality and the competition good. There is not now the keen excitement that used to attend the big class for Grapes, but in almost every district the level of quality has been raised.

A host of judges was needed to adjudicate on this occasion, and they commenced business at 9 a.m., and most of the sets had finished and the awards were placed on the prize-winning exhibits by the time the public were admitted at 10.30.

As usual, the organisation of this great show was carried out capably by Mr. Brazier and his staff, and his efforts were ably seconded by the Chairman of Committee, who had a reception on the eve of the show, at which judges, leading exhibitors and pressmen were entertained.

Groups.

The Silver Challenge Cup, valued at fifty guineas, presented by the Shrewsbury Chamber of Comerce, is offered as a first prize, plus £45, in the class for a group of miscellaneous and fine foliage plants "arranged to produce the best effect, and occupying a space of 300 square feet." This handsome award was won by Sir **George M. Kenrick** (gr. Mr. J. V. Macdonald), Whetstone, Edgbaston, with a fine effort that was well worthy of this veteran exhibitor. The whole arrangement was graceful and bright, and Mr. **Macdonald** had made the best use of Palms, Ferns, Selaginella, Humea elegans, Lilium speciosum, L. auratum, Clerodendron fallax, Begonias, Fuchsias, Codiaeums, Nandina domestica, Laelio-Cattleyas, Oncidiums, Brassias, Ixoras and Francoa ramosa. Second prize was awarded to Messrs. **James Cypher and Sons**, Cheltenham, whose display, while good, lacked something of brightness. It contained fine Palms, Humeas, Codiaeums, Haemanthus carnea, Vallotas, Lilium speciosum, L. Henryi, Ixoras, Francoa ramosa, Dracaenas and Cypripediums. Mr. W. R. **Manning**, Dudley, gained third place, and Mr. T. M. **Petch**, Bradford, fourth.

Messrs. **James Cypher and Sons** led in the less attractive class where ornamental foliage plants only were allowed in the production of an artistic group arranged on a space of 250 square feet. The premier award in this case was £35, and it was worthily won by the Cheltenham firm with a very pleasing association of Palms, Ferns, Codiaeums, Dracaenas, Acalyphas, Alocasias, foliage Begonias, Caladiums, Nandina domestica of fine colour, and an edging of the dainty little Caladium argyrites. Highly-coloured Selaginella was also used effectively. Sir **George Kenrick** won the second prize, but his display lacked the colouring seen in the first prize display. Third and fourth prizes were awarded, respectively, to Mr. W. R. **Manning** and Mr. T. M. **Petch**.

Mr. H. **Howells** won first prize for a group of flowering plants of one kind only, and his exhibit was a very attractive one of well-grown Fuchsias, some of them trained in fan-shaped style.

The best group of aquatic and bog plants was arranged by Mr. W. **Taylor**, Grinshill, who had a pleasing water garden, with a pool of Water-Lilies set amid Funkias, Trollius, Carex, Poteriums and Lythrum roseum, backed by giant Maces, Reeds and tall Thalictrums. Messrs. **Bowell and Skarratt** were placed second and Mr. P. **Gardner**, Addingham, third.

J. **McCartney**, Esq. (gr. Mr. C. Potts), Bolton, was the only exhibitor of a table group of Orchids, and was awarded the first prize for a contribution that included Odontoglossum grande in good form, Odontioda Charlesworthii, Vanda coerulea, Cattleya gigas, C. Hardyana, Epidendrum vitellinum var. majus, and Odontoglossum Lilian.

Mrs. **Fielding** (gr. Mr. G. Reynolds), Marshbrook, was the premier competitor in the class for a group of Begonias.

In the Shropshire County Class, for a group of plants arranged for effect on a ground space of 100 square feet, Mr. H. **Howells** led with a pleasing exhibit of Coleus, Trachelium coeruleum and Campanulas; Mr. J. **Savage**, Kitley, was second, and Mrs. **Fielding**, third.

Sweet Peas.

These popular flowers were shown extensively and in surprisingly good form considering the long period of drought experienced in most parts of the county.

It was a little unfortunate that in the particularly attractive class for a display of Sweet Peas, to be arranged on a table space twelve feet by six feet, the exhibits were far too close together. The competitors must have had considerable difficulty in arranging their displays at such close quarters, while the fine effect the class could have produced was entirely lost to the general public. The first prize of £15 and a trophy of the value of fifteen guineas was won by Messrs. E. **Leigh and Sons**, Tittenson—the firm that showed so well at Bakewell Show—whose exhibit was much admired by Sweet Pea specialists and those other folk who had the patience to examine it as closely as possible. Leading varieties shown were Royal Purple, Powerscourt, Mrs. Horace Wright, Sunkist, Mrs. A. Searles, Mammoth and Magnet. The flowers were allowed to be arranged in baskets, vases and any other kind of suitable receptacle, therefore the exhibitors were able to produce a fine effect. Wires or other supports for the flowers, or the exhibition of spikes with haulm attached, were not allowed. Messrs. **Herd Brothers**, Penrith, won second place, and Mr. R. **Challinor**, third.

The best dozen bunches of Sweet Peas, distinct, in a trade-excluded class, were shown by Miss K. A. **Hughes** (gr. Mr. J. Hughes), Gresford, who won with fan-shaped bunches of fine flowers of Pinkie, Model, Olympia, Powerscourt, Mrs. A. Searles, Ascot, Magnet, Bluebell, Youth, Valetta, Royal Mauve and Susan; second, Mrs. M. N. **Richards** (gr. Mr. S. Horton), Denbigh; third, Mr. W. **Weaver**, Mold. Mr. S. L. **Haycocks**, Gyfelia, Wrexham, led for six bunches, distinct, with excellent examples of Jessie, Magnet, Powerscourt, Mrs. A. Searles, Royal Mauve and Gorgeous; second, Mr. A. **Smith**.

Roses and Dahlias.

Messrs. **Gunn and Sons**, Ltd., Olton, secured the fifteen guinea trophy and £20 offered as the chief prize in the class for a collection of cut Roses artistically arranged on a space twenty feet by four feet, with a height limit of ten feet. Their display was an effective one, but the flowers were on the small side, although very bright and clean; Sunstar, Margaret McGredy, Lady Inchiquin, Mrs. Barraclough, Mrs. Henry Morse and Los Angeles were especially attractive varieties; second, Messrs. **Bees, Ltd.**

Messrs. **W. Treseder, Ltd.**, Cardiff, set up the finest collection of Dahlias, arranged on a ground space of twenty feet by five feet. Competitors were limited to a height of eight feet from the ground, and were cautioned that "lightness and effective staging, as well as quality, will be considered the test of merit." The Cardiff group contained fine flowers of several sections pleasingly arranged in stands of varying height; J. M. Davis, Edna Ferber, Dr. Helmut Spath, Emblem and Goldrose were a few outstanding varieties. Mr. H. Woolman, Shirley, Birmingham, came second, and showed H. D. Cartwright, King Tut, Salsbach's White, H. Lawrence and Hebe in great style; third, Mr. E. Clegg, Derby.

Messrs. Bees, Ltd., led for a collection of Gladioli, thus adding another fifteen-guinea trophy to their tale of awards. They had large sheaves of numerous varieties, including Rubina, Brilliant, Fire King, Yvonne, Jacoba van Bieren and Superba. Second, Messrs. Clement Dally and Co., Kidderminster; third, Mr. E. J. Bagley; fourth, Mr. R. Challinor, Balterby.

Mr. Tom Jones, Ruabon—formerly a famous Sweet Pea exhibitor—won premier honours for a dozen vases of Gladioli of the Primulinus section, and showed beautiful, clean flowers and spikes of Exenatte, Orange Queen, Salmon Beauty, Souvenir and Zanthis; Mr. T. Waterhouse, Crewe, second; and Mr. W. Samuel, Wrexham, third.

For a dozen vases of large-flowered Gladioli, Messrs. George Mair and Sons were easy first prize winners, and they showed magnificent, full-flowered spikes of superb varieties, a few of these being King George, Cecil, Ivanhoe, Corisande, Jessie, Mrs. Galbraith, Pimpernelle and Guy Mannering.

Hardy Flowers.

The fifteen-guinea trophy and £25 in cash, offered as the premier award in the class for a collection of herbaceous plants, flowers and foliage, arranged on a ground space of 250 square feet, was won by Messrs. Bees, Ltd., who had a glorious display wherein they had splendid and bold sheaves of Hollyhocks, Gladioli, Lilium Henryi, L. speciosum, L. tigrinum, L. auratum, Kniphofias, Phloxes, Liatris, Scabious, and many other fine border plants. Everything was finely grown, and the bold arrangement and gorgeous colouring arrested attention. Messrs. M. Prichard and Sons, Christchurch, secured second place, and their display was particularly notable for the superb Kniphofias it contained. These were a striking, colourful and stately feature, and some of the outstanding sorts were B. G. Prichard, Volante, Sirius, C. M. Prichard and Ruby. Other good things in this handsome collection were Crinum Powellii, in very fine condition, Lilium tigrinum, Phloxes and Gladioli.

Messrs. Bees, Ltd., secured first prize for a set of eighteen bunches of hardy flowers, and in their collection they had good examples of Gladiolus Yvonne, Cimicifuga racemosa, Yucca filamentosa, Lilium auratum and Phloxes.

Montbretias were best shown by Messrs. M. Prichard and Son, who had a very bright group of these graceful flowers. Prizes for Antirrhinums were won by Mr. A. J. Buston and Mr. E. H. Shorting. Mr. A. D. Picton, Bangor-on-Dee, had the best collection of Phloxes.

Miss Howell (gr. Mr. C. J. Burgess), showed the best set of hardy and half-hardy annuals, and contributed a fine collection of Zinnias, Tagetes, Anchusa, Alonsoa, Candytuft, Calendula, etc.; second, Colonel. T. Decker (gr. Mr. G. Gilbert), Loppington House. The best group of hardy and half-hardy annuals was shown by Mr. H. Clarke, and Mr. E. J. Bayley came second.

Floral Designs.

The various exhibits in this section appeared to be somewhat crowded, and perhaps this led to the impression that, taken as a whole, the display of floral designs was not quite up to the Shrewsbury standard.

Mr. A. Adshead showed the best three bouquets—two of Roses and one of white Carnations, and Mrs. J. Nixon was placed second. The same competitors occupied similar positions in the class for a bridal bouquet, Mr. Adshead, using white Carnations, and Mrs. Nixon, Gloriosa and Abutilon flowers.

Mrs. Nixon led for a basket of flowers, with a bright display of Celosias, Anthuriums and Gladioli; Mr. Adshead, second. For a basket of hardy flowers, Mrs. J. Nixon led with a brilliant design composed of Kniphofias, Gladioli and Chrysanthemums; Miss Newshaw, second. Miss Newsham showed the best bowl of garden flowers.

Decorated Fruit Tables.

Considerable interest invariably attaches to the class for a decorated table of fruits, the latter to consist of twenty-four dishes, in not fewer than nine distinct kinds. Not more than a dozen bunches of Grapes are allowed and these in not fewer than four varieties. The schedule contains a scale of points for judging in this class, and the points awarded (so well as the maximum) are set out on a long card and placed on each table after the judges have made their awards. These points are closely scrutinised by many gardeners who attend the show, and some interesting comments are made where the points awarded do not meet with the approval of these critics, who, of course, have not the opportunity of comparing and even handling the fruits, as have the judges.

The fifteen-guinea trophy and £30 form a handsome first prize, which was won by the Earl of Rosebery (gr. Mr. Lindores), Mentmore, Leighton Buzzard, with capital Muscat of Alexandria Grapes, Sea Eagle Peaches, Pineapple Nectarines, Souvenir de Congres Pears, and Early Transparent Gage Plums, to mention only a few of the sorts displayed. The total points came to 143½. Lady K. Curzon-Herick (gr. Mr. J. McBean), Loughborough, came second, with 140 points; Lord Belper (gr. Mr. J. McCartney), Kingston Hall, Derby, third, with 138 points; and Messrs. J. Webber and Son, Minehead, fourth, with 114½ points.

Dessert Fruits.

T. S. Hall, Esq. (gr. Mr. G. Richardson), Chard, led in the class for a dozen dishes of fruits, winning with pleasing specimens of Muscat of Alexandria and Appley Towers Grapes, Blenheim Orange and Emerald Gem Melons, Royal George and Crimson Galande Peaches, Dr. Jules Guyot Pears, Brown Turkey Figs, Jefferson Plums, Moorpark Apricots, and Pineapple and Spencer Nectarines. Second, Colonel Heywood-Lonsdale; third, Lord Swaythling (gr. Mr. F. J. Rose), Southampton; fourth, Lady Juliet Duff (gr. Mr. H. Weaver), Coombe Court, Kingston, Surrey.

Colonel Heywood Lonsdale (gr. Mr. J. Mills), Shavington Hall, secured first prize for a collection of nine dishes of fruits in nine distinct varieties and not fewer than seven kinds, winning with good Appley Towers and Muscat of Alexandria Grapes, Hale's Early and Royal George Peaches, Hero of Lockinge and Princess of Wales Peaches, Early Rivers' Nectarines and Williams Bon Chrétien Pears. Second, J. H. Jones, Esq. (gr. Mr. W. R. Catt), Buntingdale; third, Captain W. W. Hayes (gr. Mr. A. Maddock), Stanton.

Grapes.

In the principal Grape class a dozen bunches are required, in four or more varieties and no more than four bunches of one variety. The first three prizes offered are £20, £16 and £12, respectively. Here, again, the points awarded are displayed to public view, side by side with the maximum points available.

Chief honours fell to R. J. Corbett, Esq. (gr. Mr. J. Jones), Towyn, who showed Black Hamburgh, Madresfield Court, Mrs. Pince and Muscat of Alexandria in good condition, the bunches being very even and shapely, although not especially heavy. The points awarded were 85 out of a possible 116. Messrs. J. Webber and Sons came second with 83½ points out of 116, and Lady Palmer (gr. Mr. S. J. Robbins), Cefn Park, third, with 73½ points out of a possible 112.

The best four bunches of Grapes were shown by Lord Swaythling; second. Colonel Heywood-Lonsdale; the winning set was composed of excellent bunches of Muscat of Alexandria and Madresfield Court, superbly grown.

Lord Swaythling had the best two bunches of Madresfield Court Grape; Messrs. J. Webber and Sons led for "any other" black variety, and Colonel M. Hughes was first in the class for Black Hamburgh. Lady Hall and G. R. Mellor, Esq. (gr. Mr. C. Price) had the best white Muscats, with the Earl of Rosebery second.

In the Shropshire classes, Viscount Clive (gr. Mr. G. Jones), Styche; J. H. Jones, Esq., W. W. G. Phillipps, Esq., and Colonel Heywood-Lonsdale were prize-winners in Grape classes.

Vegetables.

Vegetables of fine quality filled one large tent, and it is seldom we have entered a tent where the odour of Onions was so strong as in this one. In the numerous single dish classes the produce was exceptionally good and the competition appeared to be very severe.

In the open class for a dozen distinct kinds of vegetables, Messrs. J. Jones and Son, Ammanford, won the Silver-gilt Medal and £7 offered as first prize and, as always, they showed splendid examples of fine produce, clean, fresh and well-arranged. Onions, Peas, Potatos, Tomatos, Leeks, Runner Beans, Celery and Cauliflowers were the pick of a fine set. Second, Mr. W. Robinson; third, Mr. A. H. Hickman.

Lord Riddell (gr. Mr. A. Payne), Tadworth, secured the premier awards in the class provided by Messrs. Sutton and Sons, for nine kinds; second, A. H. Hickman, Esq. (gr. Mr. J. F. Parker), Cookly, Kidderminster. In Messrs. J. Carter and Co.'s class, Mr. T. M. Jones, Llandilo, was placed first, with Mr. Hickman, second, and Mr. J. Jenkins, Aberdare, third.

Mr. W. Robinson, Garstang, led in Messrs. Clibran's class, with Mrs. H. Follard (gr. Mr. H. Watkins), Swansea, second. Mrs. F. Emnot, Lancaster, and Mr. W. H. Jones, Clive, were placed first and second, respectively, for nine kinds of vegetables in Messrs. Dickson and Robinson's class; while in the class provided by Messrs. John Peed and Son, Mr. J. Evans, Llandilo, Mr. W. Robinson and Lord Riddell were placed as named.

In the Shropshire class for nine distinct kinds of vegetables, the produce shown was again excellent; Colonel Heywood-Lonsdale won the first prize, and Mr. W. H. Jones was a good second.

Trophy and Medal Awards.

President's Prize.—This prize, a work of art valued at £25, was awarded to the Hon. Vicary Gibbs (gr. Mr. Edwin Beckett), Aldenham House, Elstree, for a large and unique display of vegetables, this being considered the finest non-competitive exhibit in the show.

Special Trophies.—These two awards—again works of art—valued at £15 15s. each, were awarded respectively to Messrs. Sutton and Sons, Reading, for their effective display of fine vegetables; and to Messrs. Bakers, Wolverhampton, for their rock and water garden, Phloxes and floral designs.

Large Gold Medals.—To the King's Acre Nurseries, for fruit trees in pots, Roses and early flowering Chrysanthemums; to Messrs. Blackmore and Langdon, for Begonias and Delphiniums; to Messrs. John Peed and Son, for stove and greenhouse plants; to Messrs. Dickson and Robinson, for Dahlias, Stocks, Gladioli, etc.; to Messrs. Dobbie and Co., for Dahlias and Roses; to Mr. Thomas Robinson, for Roses; to Mr. W. J. Unwin, for Gladioli; to Messrs. E. Webb and Sons, for annual and other flowers; to Messrs. Alex. Dickson and Sons, for Roses; and to Messrs. J. Kelway and Son, for Gladioli.

Gold Medals.—To Messrs. Allwood Bros., for Carnations and hybrid alpine Dianthi; to Messrs. W. Lowe and Son, for Roses; to Messrs. S. McGredy and Son, for Roses; to Messrs. E. Murrell, Ltd., for Roses and hardy flowers; to Mr. Klinkert, for Topiary; to Messrs. W. H. Simpson and Sons, for Antirrhinums and Phloxes; to Messrs. Dicksons (Chester), for Gladioli, etc.; to Messrs. Daniels Brothers, for hardy flowers and vegetables; to Messrs. Jarman and Co., for hardy flowers; and to Mr. F. Rich (Worcester), for hardy flowers.

Silver-gilt Medals.—To Mr. H. Clarke, Taunton, for hardy flowers; to Messrs. Pritchard and Sons (Shrewsbury), for Roses and hardy flowers; to Mr. W. Wells, junr., for Phloxes; to Mr. H. N. Ellison, for Ferns; to the Rolvenden Nurseries, for Statice profusa var. superba; to Mr. H. S. Woolman, for Dahlias, etc.; to Mr. C. Vickers, for floral designs; and to Messrs. Rich and Cooling, for hardy flowers.

ROYAL HORTICULTURAL.

August 27.—Probably owing to the fact that most of the leading nurserymen were at Southport, the show held in the new hall in conjunction with the meeting of the above Society on this date was a small affair. There were no exhibits of Orchids, but the displays of herbaceous flowers, Dahlias, Roses, Carnations and shrubs helped to fill the central portion of the hall, the aisles of which were not utilised. The Orchid Committee recommended Awards of Merit to two out of the several novelties shown before it, and one Certificate of Preliminary Recognition. The Floral Committee recommended three Awards of Merit, and the Fruit Committee recommended two seedling Plums for trial at Wisley. The Joint Dahlia Committee, which sat for the first time this season at this meeting, recommended three Dahlias for trial at Wisley.

Orchid Committee.

Present: Mr. Lionel de Rothschild (in the chair), Mr. Gurney Wilson (Hon. Secretary), Mr. A. Dye, Mr. J. E. Shill, Mr. J. C. Cowan, Mr. T. Armstrong, Mr. E. R. Ashton, Mr. Stuart H. Low and Mr. S. W. Flory.

Awards of Merit.

Miltonia Bleuana var. Langley Ruby (M. Bleuana var. Reine Elizabeth selfed).—A very charming variety, of velvety ruby-crimson colouring, margined with white. The upper sepals are recurved, while the disc at the base of the large, lobed lip is primrose-yellow. Shown by Messrs. Black and Flory.

Laelio-Cattleya Titymona var. Rotunda (Cattleya Tityus × L.-C. Monus).—An exquisite bloom of grand form and size, the sepals and frilled petals being rose-lilac in colour, while the large, frilled lip is rich, velvety reddish-purple, with a yellow, veined throat. A very handsome Orchid, shown by R. Paterson Esq. (gr. Mr. A. Merry), Stonehurst, Ardingly, Sussex.

The only other award made by this Committee was a Certificate of Preliminary Recognition to Miltonia memoria H. T. Pitt var. Exquisita, also shown by R. Paterson, Esq. The flowers are velvety-crimson, shaded with pale pinkish-lilac, with a small biscuit-coloured eye.

Floral Committee.

Present: Section A.—Mr. H. B. May (in the chair), Mrs. Wightman, Mr. C. E. Pearson, Mr. D. Ingamells, Mr. D. B. Crane, Mr. W. B. Gingell, Mr. J. M. Bridgeford, Mr. W. Howe, Mr. M. C. Allwood, Mrs. Lindsay Smith, Mr. C. F. Langdon, Mr. Hugh Dickson, Mr. A. E. Vasey, Mr. J. B. Riding and Mr. W. D. Cartwright, Secretary.

Section B.—Mr. C. T. Musgrave (in the chair), Mr. E. A. Bowles, Mr. G. Harrow, Mr. G. Reuthe, Mr. A. Bedford, Mr. F. G. Preston, Mr. Reginald Cory, Mr. Mark Fenwick and Lady Beatrix Stanley.

Awards of Merit.

Hedychium Gardnerianum.—An enormous inflorescence of this striking Himalayan species was shown. The stout flower-spike was nearly eighteen inches tall, the numerous slender-petalled, yellow blooms, with long, protruding, reddish stamens, being arranged in perpendicular rows. This species, which has been described as the queen of the genus, is figured in the *Bot. Mag.*, t. 6,913. Shown by F. Kemp, Esq., Hayward's Heath.

Crassula sarcocaulis.—Although not new to cultivation, this attractive little semi-hardy Succulent is not often met with. It succeeds out-of-doors in a sunny position on the rock garden, in light, well-drained, loamy soil, and under such conditions may survive an average English winter, especially if provided with overhead shelter, but it is best grown as an alpine house subject. The specimen shown was a rounded bush about eight inches high, the gnarled branches imparting to it an appearance of old age. The short, young growths are clothed with small, narrow, fleshy, glaucous leaves, and are each terminated at this season of the year with compact clusters of small, pink, tubular flowers, toothed at the mouth to impart a star-like appearance, and reddish on the outside. This plant is sometimes offered by alpine plant nurserymen, and is well worth securing. Shown by The Director, R.H.S. Gardens, Wisley.

Chrysanthemum Winnie Avery.—An attractive Decorative variety which should prove useful for market purposes. The shapely blooms, with incurving petals of good texture, are bright golden-bronze in colour. Shown by Mr. C. T. Kipping, Althorne, Chelmsford.

Groups.

Perhaps one of the most striking exhibits at this meeting was a grand display by Messrs. Sutton and Sons, of Asters in various types and in many shades, from pure white to purple and scarlet, the Mammoth and Ostrich Plume varieties being exceptionally fine.

Mr. H. Hemsley showed a mixed collection which embraced Dahlias in variety, including several splendid Cactus and large-flowered Decorative sorts, with a central mass of Sidalceas in several colour shades. Herbaceous flowers, including several first-class Phloxes, together with Lupins, Delphiniums, Heleniums and Liatris, were charmingly arranged by Messrs. E. J. Redgrove and Sons; the Misses K. and E. Hopkins also had a small group of herbaceous subjects. Coreopsis, Heleniums and other herbaceous flowers were exhibited by Mr. A. Miles, while Mr. S. F. Goodliffe staged Dahlias in variety and of good form, together with Eryngiums, Scabiosa caucasica, Phloxes, Lupins and Delphiniums; a small but very attractive display.

Messrs. Dawkins arranged a group of exceptionally well-grown African Marigolds in two varieties, Improved Lemon and Improved Orange, both of rich colouring, in association with the dainty, dwarf Coreopsis Tom Thumb Beauty.

Messrs. S. Bide and Son, Ltd. showed Sweet Peas in grand condition, their outstanding varieties being Youth, Picture, Magnet, Purple Perfection and Model. Roses were displayed by Messrs. B. R. Cant and Sons, Ltd., Mr. J. H. Pemberton and Messrs. Allens, the last-named firm showing lovely pillars of Emma Wright, Golden Emblem, Charles P. Kilham, Dame Edith Helen and Etoile de Hollande.

Messrs. H. Langridge and Co. were responsible for a small group of Dahlias of various sorts, chiefly of the large-flowered Decorative type, with a background of grand spikes of Gladioli, including such beautiful Primulinus varieties as Alice Tiplady, salmon; Flora, cream; Dawn, Marechal Foch and Orange Queen.

Messrs. Allwood Bros. put up a small collection of perpetual-flowering Carnations, together with their hybrid Dianthus Sweet Wivelsfield, but the display was not up to their usual standard. A much better group of Carnations was set up by Messrs. C. Engelmann, Ltd., who arranged Canadian Pink, Topsy, Blanche, Laddie, Saffron, White Pearl and several other good sorts with charming effect.

In the centre of the hall, Messrs. R. C. Notcutt staged an interesting bank of shrubs, including several forms of Buddleia variabilis, fruiting branches of Cornus alternifolia, Viburnum orientalis and Pyrus cathayensis, together with such late-flowering shrubs as Potentilla fruticosa var. Farreri, Hypericum patulum var. grandiflorum, Cornus paucinervis, Cytisus nigricans, Perowskia atriplicifolia, Spiraea Douglassii, Hydrangea paniculata var. grandiflora and Romneya hybrida.

Messrs. Hollamby's Nurseries arranged ornamental and well-flowered plants of Clematis varieties in association with heavily-fruited pot plants of Pyracantha coccinea and its variety Lelandii, the fruits of which were richly coloured and associated well with the Clematises.

Joint Dahlia Committee.

Present: Mr. H. B. May (in the chair), Mr. J. Cheal, Mr. J. Emberson, Mr. J. B. Riding, Mr. A. E. Vasey and Mr. D. B. Crane.

This Committee recommended three large-flowered Decorative sorts, all of which were shown by Messrs. J. Stredwick and Son, for trial at Wisley. The varieties so honoured were Daily Mail, with large, curled petals, yellow, shaded with orange; Charles A., glowing scarlet, tinged with orange in the centre, the petals being tipped with white, and Magician, with curled, rich primrose-yellow, white-tipped petals, the outer ones being lightly shaded with orange.

Fruit and Vegetable Committee.

Present: Mr. E. A. Bunyard (in the chair). Mr. W. H. Divers, Mr. J. C. Allgrove, Mr. H. Markham, Mr. E. Beckett, Mr. J. Wilson, Mr. J. Cheal, Mr. T. Pateman and Mr. A. N. Rawes, Secretary.

Several interesting novelties were submitted to this Committee, which recommended two seedling Plums for trial at Wisley. These were Plum Black Prince (Kentish Black Diamond × Bradley's King Damson), with dark purple fruits, richly flavoured and of medium size, and thickly covered with "bloom," shown by Messrs. Laxton Bros., and a seedling of Victoria Plum, with enormous fruits richly coloured with red over a greenish-yellow ground, shown by A. Worsley, Esq., Mandeville House, Isleworth.

Mr. J. C. Allgrove exhibited an interesting fruit which was half Nectarine and half Peach, on a tree of Peach Peregrine.

Groups.

An interesting collection of dishes and baskets of Apples was set up by Messrs. S. Spooner and Sons, and included good fruits of Lady Sudeley, Worcester Pearmain, Langley Pippin, Grenadier, Lord Suffield, Red Victoria, Hunt's Early and Lord Grosvenor. They also had fruiting sprays and a dish of excellent fruits of Blackberry Theodore Reimers. Messrs. Daniels Bros., Ltd., showed sprays and chip baskets of their well-known late Black Currant, Daniels' September.

ELGIN.

August 21 and 22.—In no county of the British Isles is the cult of gardening more enthusiastically engaged in than in the fair land of Morayshire, aptly termed the "garden of Scotland." Rich and poor alike all vie in the cultivation of flowers, with the result that the premier show of the county staged by the Elgin Horticultural Society is invariably one of the finest floral events in Scotland. The quality and deep, rich colouring of the exhibits can be bettered nowhere. Of course, Morayshire has a fine climate.

Under the able guidance of Mr. T. L. Mann, this annual event is becoming better and better as the years roll on. He is the scion of an old and highly esteemed gardening family, and his knowledge of everything pertaining to horticulture makes him an ideal Secretary. The Hon. James Stuart, M.P. for Moray and Nairn, opened the show, while the Duchess of Richmond and Gordon added *éclat* to the proceedings by presenting the leading prizes. These included a Silver Rose Bowl for most points in Sweet Peas, Mr. James Macintosh, Aberdeen; Silver Cup for most points in the professional classes, Mr. J. M. Annand, Brodie Castle Gardens; Silver Cup, for most points in amateur classes, Mr. J. McGillivray, Newton Road, Elgin; Silver Medal, for best vase of Sweet Peas in the show, Mr. A. S. Dow, Darnaway Castle Gardens; the Society's award for the best exhibit at the show (confined to members), Mr. T. L.

Mann; and Silver Cup for the best garden of municipal houses, Mr. Charles Petrie, Maisondieu, Elgin.

Pot Plants.

This section, professional and amateur, proved exceedingly good, The Brodie of Brodie (gr. Mr. J. Annand), Brodie Castle, had a fine entry of Adiantums. Begonias (single) were best shown by Mr. Ian K. Thomson (gr. Mr. J. Ferguson), Burgie House, while Mr. Herbert C. Bilby (gr. Mr. J. Short), Blackfriars Haugh, had the finest doubles. The Asylum Gardens (gr. Mr. J. McLaren), while taking only one first (Hydrangeas), had a good place in most of the other classes.

Cut Flowers.

Brodie Castle Gardens provided some excellent specimens of perennials, annuals and Chrysanthemums. Burgie House led for Stocks, Pelargoniums, Cactus Dahlias, Asters and cluster Roses. Darnaway Castle Gardens had the best Antirrhinums and Blackfriars Haugh led finely for Dahlias, Carnations and Roses.

Sweet Peas.

The Sweet Pea section gave unfeigned pleasure to the many visitors, including, as it did, exquisite specimens of this favourite flower. For the best twelve vases, distinct varieties, the honours went to Darnaway Castle, and also for pink and purple varieties. Cairnfield Gardens (Buckie) were best for scarlet, one vase Sweet Peas any other variety, and one vase of a novelty for 1929. Mr. James Macintosh, Rosefield Cottage, Aberdeen, took leading places for three vases of Sweet Peas, distinct, one vase lavender, and one vase white.

Fruits.

Nothing finer has ever been seen at Elgin than the fruit display this year. That doyen of northern gardeners, Mr. Charles Webster, Gordon Castle Gardens, who has been a judge more times than he can remember in such matters, declared that the display was one of the finest he had ever seen, and one that even the Edinburgh show, noted for its fruit display, could not better.

Darnaway Castle Gardens (gr. Mr. A. S. Dow), romped home in fine style for Apples, dessert and baking; Pears, Red Currants, Raspberries, and the best collection of hardy fruits. Mr. F. J. Tennant, Innes House (gr. Mr. John Nicoll) led for Grapes, and Mr. A. A. Dunbar Brander, for Nectarines. Burgie House, Forres, had remarkably fine winning displays of Gooseberries (green or white), Gooseberries (red), and Black Currants. Mr. J. Grant, High Street, Elgin, led for Plums, with remarkably fresh and clean-grown specimens, with the produce of Darnaway Castle Gardens and Brodie Castle Gardens following close behind. The Glen of Rothes (gr. Mr. W. Logan) sent the best Strawberries; Blackfriars Haugh Gardens (gr. Mr. J. Short) led for Loganberries. This section was an outstanding feature.

Vegetables.

They can grow vegetables in Morayshire, and nowhere better than in Brodie Castle Gardens (gr. Mr. J. Annand). The produce from here carried off premier honours for the best collection of vegetables, Potatos (kidney), Turnips, Beet (globe), Parsnips, Celery and Cucumbers. Burgie House (gr. Mr. J. Ferguson) led for the best collection of Potatos (four varieties); round, white Potatos; Broad Beans, and Peas. Glen of Rothes secured premier places for Shallots, Beet (globe), Cauliflowers and Cabbages. Innes House sent the best Onions and Vegetable Marrows. Generally, it was a capital display, and reflected great credit on all concerned.

Trade Displays.

Trade exhibits were well to the fore, Messrs. Allwood Bros., Haywards Heath, Sussex; Messrs. Austin and McAslan, Glasgow, and Mr. T. L. Mann, florist, Elgin, had exquisite displays. Mr. J. G. White, Aberlour Orphanage, showed specimen Begonias in fine condition. Seldom, indeed, have Begonia blooms been seen in such perfect condition.

ROYAL SCOTTISH ARBORICULTURAL.

(Northern Branch.)

The annual meeting of the members of this branch was held in Inverness, the headquarters of the Society, with Mr. Gilbert Brown, Vice-President, in the chair. Mr. David Ross, Secretary, gave a resumé of the past year's work, which showed the finances in a very satisfactory state. His remarks included warm praise for the tree-felling competition held under the auspices of the branch, the details and result of which were given in *The Gardeners' Chronicle*. Eight counties entered the competition, sending eighteen teams. The first of its kind, the results were so satisfactory that the branch determined to arrange another felling competition. The election of office-bearers followed, when the Chairman proposed that Colonel Neil Fraser-Tytler, of Aldourie, be re-appointed President, which was heartily agreed to. Mr. Gilbert Brown and Mr. Frank Sime were re-elected Vice-Presidents. The following were appointed as the Executive Committee:—Mr. Alex. Fraser, forester, Brahan; Mr. George E. Johnston, factor, Novar; Major Scott, Forestry Commission, Inverness; Mr. Singer, Fairburn, Muir of Ord; Mr. Home, Forestry Commission, Fort-Augustus; Mr. Anderson, Inverfarigaig; Mr. Macdonald, Redcastle; and Mr. H. C. Noble, factor, Contin, Strathpeffer.. The following members were added:—Mr. Matthew Feaks, Darnaway; Mr. William Breingan, Aldourie; Captain Macintosh, Kyllachy; and Mr. Murdo Ross, Allangrange. The members resolved to visit Cawdor Woods on Saturday, August 31, having received a letter from Colonel Baillie saying he would be very pleased to show the members over the policies of Cawdor.

READING GARDENERS'.

The final evening meeting of the summer session was held by the kind permission of Mr. H. C. Sutton at Benham Park, Newbury, on the evening of August 19, when between sixty and seventy members availed themselves of the opportunity of inspecting the extensive gardens and grounds of this charming Berkshire seat.

On arrival, the party was welcomed by Mr. Smith, the gardener, who at once conducted the visitors through the houses. Space will only permit of noting some of the principal features. In the vineries (six houses) there were excellent crops of Black Hamburgh, Madresfield Court, Lady Downe's and Muscat of Alexandria Grapes; while in the five houses devoted to Peaches and Nectarines, although several varieties had already been gathered, there were heavy crops of Bellegarde and Dymond.

In the Fig house there is only one tree, but its growths filled the entire structure. It was planted in 1866, the year in which the late Sir Richard Sutton won the Derby with Lord Lyon. Tomatos were a heavy crop, the variety grown being Best of All. Carnations were excellent, the most noticeable varieties being Topsy, White Pearl, Scarlet Carola, Countess of Lathom and A. J. Cobb. In the plant houses, Statice, Browalias, Crotons, Lilies, Phloxes and Salpiglossis made a bright show; there was also a fine batch of Begonia Gloire de Lorraine.

The herbaceous borders, although past their best, contained a large variety of plants still flowering well, notably Phloxes, Verbascums, Salvias and Monarda didyma.

Apples were a fair crop, while Pears, Peaches, Plums and Morello Cherries were excellent.

A walk through the park brought the party to the mansion, where the Italian and Terrace gardens attracted much attention. From the top terrace, which was confined chiefly to Roses, magnificent views were obtained, particularly across the valley to Beacon Hill, Highcliffe. The Yew hedges are quite a feature of this part of the gardens. A pleasant ramble by the lake (sixteen acres) brought to a close one of the most enjoyable evening meetings yet held by the Association.

Before separating, a hearty vote of thanks was tendered to Mr. Sutton for his courtesy in throwing open his gardens and grounds to the members, and to Mr. Smith for the interest he had taken in the visit. Congratulations were also given him for the splendid upkeep of the gardens.

UNITED HORTICULTURAL BENEFIT AND PROVIDENT.

The monthly meeting of this Society was held at the R.H.S. Hall, on Monday, August 12, Mr. Charles H. Curtis presiding. Seven new members were elected. Two members withdrew the sum of £57 15s. 4d. from their deposit accounts, and £169 5s. 6d. was passed for payment to the nominees of four deceased members. Sick-pay on the Ordinary side amounted to £77 9s. 8d., and in the State Section to £65 10s. 4d.; and maternity benefits totalled £5. Grants to the amount of £34 6s. 6d. were made to eight members towards dental and surgical treatment, and several other cases were considered.

Obituary.

Conway Jones.—Through the recent death of Mr. Conway Jones, at the advanced age of eighty-three, Gloucester has lost one of its noted citizens, and a great amateur Rosarian has gone to his rest. Outside the city in which he was born and bred it was as a grower and exhibitor of Roses that Mr. Conway Jones was best known, and in this respect he was pre-eminent, winning, among many other trophies, the National Rose Society's Amateur Champion Challenge Trophy with the Gold Medal of the Society. It was in the 'nineties that Mr. Jones commenced to show Roses from less than a hundred trees, in the days of the Gloucester Rose Society, of which he was Chairman of Committee, but he was enterprising and ambitious, and by the time he reached the zenith of his fame, about 1900, his stock probably exceeded 10,000 plants. In 1895, the National Rose Society held its Provincial Show at Gloucester, when Mr. Jones upheld the reputation of his native city by winning a number of the leading prizes. Mr. Conway Jones was essentially a man of varied activities; in addition to being a keen man of business, a city councillor for some years, and a great Rose-grower, he was a keen angler, a popular member of the Masonic craft, and in the hard winter of 1890-91 he performed the feat, never since repeated, of riding his tricycle for a considerable distance on the frozen Severn outside Gloucester. Owing to ill-health, the genial presence of Mr. Jones has been missed in the city for some time past, and his passing marks the end of a man who really loved Roses, and knew how to grow them.

Theodor Gronenberg.—We learn from the German horticultural press of the death on July 27 of Theodor Gronenberg, at Memel, East Prussia. Born in 1863, at Lindnau, after the completion of his general education and a short training in horticulture, he proceeded to Berlin to perfect himself in nursery work. He obtained a position in the gardens of Potsdam Palace, where he stayed three years or so, and after some further experience, in 1896 he was able to fulfil his ambition by buying a small nursery establishment of his own, in Memel. With the aid of his wife, and by dint of strenuous work, he increased the size and importance of the nursery very considerably, but the war of 1914-18 brought troublous times and the business subsequently suffered severely by the partition of East Prussia. However, by the efforts of himself and his son, who took over the business and had latterly carried it on, the difficulties were surmounted and successfully overcome. Herr Gronenberg will, perhaps, be best remembered by the prominent part he took in organising the growers in East Prussia, and he was always a welcome guest at their re-unions.

Camille Potrat.—We regret to hear of the death on July 24, at the age of fifty-nine, of M. Camille Potrat, a prominent official in the horticultural service of the Paris municipality, and also a Professor of the Horticultural College of Saint-Mandé (Seine). He took a keen interest in all matters pertaining to his profession, and was a Vice-President of the Old Scholars' Association of the Versailles Horticultural College, and of the French Gardeners' Association; he had the distinction of having been created Commandeur du Mérite Agricole and Officier de l'Instruction Publique. His special study was that of kitchen garden cultivation, but he had a very complete knowledge of horticulture as a whole, and had, indeed, been appointed, soon after the completion of his studies at Versailles, gardener to Prince Murat. He was an industrious writer on horticultural subjects, and besides contributing to the press, had written two books, on vegetable culture and on Melon-growing, respectively.

William Edward Slora.—Keen regret will be felt among his many friends by the death of Mr. William Edward Slora, which took place at his residence, Deemount Road, Aberdeen, on Wednesday, August 21. One of the best and most widely-known gardeners and florists in and around Aberdeen, Mr. Slora was trained by his father, also an expert gardener, on the Bloomfield Nurseries, situated then on the outskirts of Aberdeen. When only twenty-five years of age the deceased started out on his own, and for the past forty years has occupied an important place in his profession. Exceptionally well-skilled in laying out golf courses, Mr. Slora was responsible for the three best courses in Aberdeen—Balgownie, Balnagask and Hazlehead—besides many other important undertakings. Unfortunately, during the past five years, Mr. Slora was incapacitated through ill health, his place being filled by a son who has been associated with him in the business. Deceased was sixty-five years of age; he was an ardent admirer of Robert Burns, and leaves a widow, two sons and eight daughters.

ANSWERS TO CORRESPONDENTS.

Apple Foliage Unhealthy.—*L. P.* The Apple leaves show symptoms of leaf-scorch, which is of a physiological nature and arises usually from a deficiency of potash in the food of the plant. The problem is a very complex one, but it is found in most cases that potash manures tend to reduce the amount of scorch. Dress the ground beneath the trees in autumn with sulphate of potash, previously satisfying yourself that the drainage is satisfactory.

Turf in Bad Condition.—*A. P.* The dead patches on your lawn are, in our opinion, due to burning, and there may be various reasons which may account for this, *i.e.*, a leakage of petrol from the mower or roller, applying a fertilizer carelessly in dry weather, and dogs. The condition of the turf submitted is consistent with any one of these reasons. The fibre is quite healthy, but the grass appears to have been scorched, and it is evident the brown patches are the result of some injurious matter applied to the surface. The fact that dogs are let loose on the lawn every morning (particularly females) during this prolonged spell of drought, inclines us to believe that the dogs are responsible for the brown patches. We would suggest a dressing with a fumigant (Terrafumite) well watered in. The fumes of this material will keep the dogs away. Later, scarify the brown patches and, if necessary, add a little loam and sow fine grass seeds. Keep the patches moist until germination takes place. We would also suggest that you discontinue using a five-ton roller. A four-cwt. roller is, in our opinion, of sufficient weight for any lawn, and particularly so on a clay soil.

Remarks.—In this department, the requirements during August are usually very erratic and supplies generally are more than sufficient for the demand. Prices during the past week have not shown any improvement. Carnations show no change, but good Roses are less plentiful, especially red blooms. Chrysanthemums, both disbudded blooms and sprays, are still on the increase, but larger quantities have been moved during the past week; sprays have been greatly welcomed. There is a glut of Asters at the present time, but good Stocks are very scarce. Gypsophila paniculata flore pleno is very scarce. The latest arrival in this department is Physalis, in fine condition.

Remarks.—Business has not been active during the past week. Quantities all round are unusually heavy and generally produce has gone out fairly well, but values, in most instances, are lower. In the hothouse Grapes section business is slow, and the demand for the choicer fruits is not good. Plums are comparatively cheap; the quantities of Czar that have been marketed are on a record scale. Victorias are coming along quickly and values are easier. There are heavy supplies of English Apples on the market, but the proportion of really good-class fruits is small. Second grade Apples, both dessert and culinary varieties, are not selling well. There are increasing quantities of Pears available and on the whole they are cheap. Cucumbers are a really bad trade, and even low prices do not encourage sales. Tomatos are easier all round, quantities being heavy and the demand poor. Mushrooms are a steady trade, with stable values. Salads are variable and in small demand. Green vegetables are meeting but poor support from buyers, and Potatos at the moment are in excess of demand.

GLASGOW.

While cut flowers generally continued cheap last week, Chrysanthemums, which are now arriving in larger quantities, realised satisfactory prices. Selected disbudded blooms were worth 5s. per dozen; Mary Colville and Bronze Early Buttercup, 2s. 6d. for 6's; White Countess, 1s. to 2s. 3d.; Mercedes, 1s. 6d. to 2s.; Holicot Bronze, 1s. 3d. to 1s. 9d.; Holicot Yellow, 1s. to 1s. 9d.; Elsie Headie and Sanctity, 1s. to 1s. 6d.; Phoenix, 10d. to 1s. 6d. for 12's, and sprays, 3d. to 1s. each. Gladioli were again slow to move at prices ranging from 6d. to 3s. per dozen. Carnations fluctuated between 1s. and 1s. 9d. per dozen; pink Roses, 1s. 9d. to 3s.; red, 1s. 6d. to 2s. 6d.; white and yellow, 1s. to 2s.; Richardias, 2s. to 3s. per bunch; Statice, 5d. to 8d.; Sweet Peas, 1d. to 6d.; Dahlias, 5d. to 6d.; Stocks, 3d. to 6d.; Asters, Marguerites and Calendula, 2d. to 3d.; Nigella, 3d.; Smilax, 1s. to 2s.; Asparagus, short, 4d. to 6d.; medium, 9d. to 1s. 3d.; and trails, 1s. 6d. to 3s.

Business in the fruit market was fairly active. Strawberries realised 10d. to 1s. 4d. per lb.; Raspberries, 2s. 6d. per sieve (12 lbs.); Czar and Early Rivers, 2s. to 3s. 6d.; special, 5d. per lb.; Victoria (Middlesex), 6d. to 9d.; home-grown Melons, 3s. 6d. each; Pineapples, 4s.; Canteloupes, 9d. to 1s. 6d.; Peaches, 5s. to 12s. per dozen; cooking Apples, 2s. to 3s. per sieve; American Apples (Gravenstein), 17s. to 20s. per case; Beurré Hardy Pears, 28s. to 29s.; Grape Fruits, 26s. and Oranges, 15s. to 22s.

Tomatos declined to 4d. and 5d. per lb.; Cauliflowers and Cucumbers made 2s. to 4s. per dozen; Lettuces, 1s.; French Beans, 3d. to 4d.; Marrows 6d. to 8d.; and Mushrooms, 2s. per lb.

Coloured Supplement Plate.

Dendrobium Thwaitesiae, Veitch's var.

Average Mean Temperature for the ensuing week deduced from observations during the last fifty years at Greenwich, 58·3°.

Actual Temperature—

The Gardeners' Chronicle Office, 5, Tavistock Street, Covent Garden, London. Wednesday, September 4, 10 a.m. (Greenwich time). Bar. 30. Temp. 70°. Weather, fine.

The "Cut Flower" Garden.

Gardeners pure and simple, and most are one if not the other, grow plants for the sake of seeing them grow. Achievement—although not to be despised—is less to them than the exercise of their art. To such the laying on of hands in the garden is to be resented, fiercely or morosely, according to temperament, and hence it comes that we gardeners sometimes get a truly undeserved reputation for being difficult. As, for example, when we fail to be pleased that a plant brought after much trouble to florescence disappears in the day of its prime to bedeck the dining or drawing room. If only "they" had taken something else—no matter what—we should not have repined, but this, the Apple of our eye! It is too much. Of course, there are stoics among gardeners who can witness the cutting off of their nearest and dearest plants in their prime without a murmur. They cheerfully surrender all the work of their hands for the good of the household, and are rightly held in much esteem. But we more sensitive souls who cannot acquire such indifference or callousness, how are we to save ourselves from loss of plants and loss of temper? Wife and child are dear to us; our domestics have our esteemed consideration, but our flowers are precious also, and the garden which we have been making all these years must have some protection from the ruthless "picking for the house." In large, well-ordered places, all things are provided for, and out of the plentitude of floral and leafy production the needs of the household are easily and smoothly met—or, at all events, they should be. But in the smaller garden, with many indoor devotees of flowers, and particularly in the garden in the making, the cut flower problem is a serious one. In the early days, of course, it does not arise. There is nothing to cut, and all the gardener has to bear is advice on how a garden should be planted in order to yield plenty of flowers, fruits and vegetables at all seasons, and particularly in mid-winter, when such things cost so much to buy. Then later, his day of triumph comes, and the garden is suddenly a garden. That is the dangerous age. The shrubs and trees still require nursing if they are to become fine specimens, and yet in all innocence, of course, they become a lure to the garden depredator intent on house decoration. The wise gardener, of course, anticipates these troubles, and by anticipating, ends them. He creates a "cut flower" garden wherein the household may make free, and in exchange exacts an undertaking that anything elsewhere that may be required may be had only by the asking of himself. The agreement may be honoured, but there is always the difficulty that we want that which we may not have. In any case, the scheme is worth trying, and we ourselves have known it to meet with partial success. The making of such a garden is, moveover, an interesting work. There must be plenty of foliage for spring, summer and autumn effects, and, of course, there must be plenty of flowers in endless succession. Perennials must form the framework and annuals fill the interstices. There are all sorts of curious facts to be gleaned in such a garden. What flowers last longest when cut? How may the life of cut Poppies and the like be prolonged? What colours harmonise best with the rather feverish electric light so often used nowadays? Unfortunately, so popular have flowers become that it needs a large cut flower garden to supply a small household. Seasons will, moreover, play unkind pranks in these and in all other gardens, but the better the gardener the more powerless are the seasons—the garden fates—to embarrass him. Beside the fresh flowers, the cut flower garden should provide large supplies of "Immortelles"—Helichrysums, Acrocliniums, Statice, Eryngiums and Echinops, for the making of bouquets for winter decoration; herbs and Roses for pot-pourri; Lavender and Rosemary, and incense plants brought on indoors and planted out in shelters and warm places. It would, indeed, be worth someone's while to write a brochure on the cut flower garden. If well done it would win much gratitude, both for the member of the household who looks after indoor floral decoration, and the member who takes charge of the garden itself. Although, nowadays, we are all gardeners, our objectives are not all identical. Some love the garden as a source of supply and some love it for its own sake. The cut flower garden might help to bridge the gulf between them.

Our Coloured Supplement Plate.—Probably no hybrid Dendrobium is more richly coloured than D. Thwaitesiae, a hybrid raised many years ago by Mr. Richard Thwaites by crossing D. Ainsworthii var. splendidissimum grandiflorum with D. Wiganiae. Several forms of this brilliantly coloured hybrid have appeared, but that known as Veitch's var. is certainly one of the best. It is this form that is depicted in the Coloured Supplement Plate presented with this issue, and the flowering stem figured represents one of many shown by the late J. J. Bolton, Esq., of Claygate Lodge, Claygate, Surrey, whose collection of fine Orchids was cultivated so splendidly by Mr. S. Lyne.

John Cypher Memorial.—Our readers will remember that letters have appeared in this journal from November 24, 1928, onwards, suggesting that a fund should be raised for the purpose of providing a permanent memorial in memory of the late Mr. John Cypher, V.M.H. The idea of such a memorial originated with a few exhibitors who had been in many ways and places associated with Mr. J. Cypher, who was one of the foremost competitive exhibitors of modern times, especially of Orchids, stove and greenhouse plants, and artistically arranged groups. The letters referred to did not bring the response anticipated, and the many friends of Mr. Cypher felt that the memorial fund should be launched at some important gathering of horticulturists. Chelsea Show offered no opportunity; moreover, the atmosphere was not congenial to the product, as Chelsea is a non-competitive exhibition. Shrewsbury also did not afford an opportunity, and it was left to the large and important gathering in the Town Hall on the eve of the Southport Show to launch the scheme. The Mayor of Southport and the Show Committee provided the necessary opportunity for Mr. C. H. Curtis to set forth the views already expressed by Sir Jeremiah Colman, Bart., Mr. N. F. Barnes, Mr. F. Jordan, Mr. R. Greenfield, Mr. Allan Falconer and others; he asked that if those present were in agreement with the general principle of a memorial, a Committee should be formed to materialise it. Mr. Alderman Wood, Chairman of the Southport Show, expressed approval of the scheme, and stated that his Committee would donate £25 to the fund. After Mr. Barnes and others had spoken, a Committee was appointed as follows: Mr. N. F. Barnes, Eaton Gardens, Chester; Mr. H. E. Alexander, Westonbirt, Tetbury; Mr. J. S. Brunton, *Horticultural Trades' Journal*, Burnley; Mr. N. J. Macself, *Amateur Gardening*, 148, 149, Aldersgate Street, London, E. C.; Mr. David Cuthbertson, of Messrs. Dobbie and Co., Edinburgh; Mr. R. F. Felton, Hanover Square, London, W.; Mr. Robert Greenfield, c/o Messrs. John Peed and Son, West Norwood; a representative from the Southport Show Committee; a representative from the Shropshire Horticultural Society; a representative from the Royal Caledonian Horticultural Society; a representative from the Glasgow Show; and Mr. Thomas Hay, representing the Royal Horticultural Society; with Mr. Charles H. Curtis, Managing Editor of *The Gardeners' Chronicle*, as Hon. Secretary and Treasurer, to whom, at 5, Tavistock Street, Covent Garden, W.C., subscriptions should be sent. Mr. Curtis's appeal for donations met with a ready response at Southport, where a total of about £117 was promised, in amounts ranging from 4s. to £25. We hope to publish a list of donations in our next issue; meantime, every subscription, however small, will be acknowledged through the post. The exact form the John Cypher Memorial will take will be determined by the Memorial Committee in accordance with the amount received and after due consideration of the views expressed by subscribers.

Elm Disease in Germany.—The Elm disease which has attacked and killed so many fine street and park trees in Holland and England during the past few years has found its way to Germany, where two forms of the disease, the acute and the chronic, have made their unwelcome appearance. The result in each case is the same, that the tree perishes, the difference being only in the time taken for the disease to have its fatal effect. It is remarked that up to the present, only trees in the streets and parks have been attacked, those in woodlands and coppices appearing free from the disease.

"A Tentative List of Tulip Names."—The publication of *A Tentative List of Tulip Names* is a step towards the fulfilment of a long-felt want among horticulturists in general, and Tulip-lovers in particular, for it is a preliminary attempt to unravel the confusion of nomenclature which now exists among Tulips, and will, therefore, be welcomed by the great bulb-loving community, while it should prove of special value to bulb dealers. This direct attempt to stabilise Tulip nomenclature is the outcome of the work of the Tulip Nomenclature Committee, on which both British and Dutch growers are represented. It is to the General Bulb Growers' Society of Haarlem that the Royal Horticultural Society, and Tulip-growers in general, primarily are indebted for the production of the present list, as this Society kindly undertook the preparation of a provisional list of names, to act as a basis upon which the Nomenclature Committee could work; this list had as its foundation the classification and list of names given in the Report of the Tulip Nomenclature Committee, 1914-1915, but since that Report two new classes have come into existence, namely, "Mendel" Tulips and "Triumph" Tulips. As many cases of synonymity are suspected in these two groups, which can only be cleared up after a series of trials, it has been deemed advisable to omit from the present publication the names of Tulips belonging to these new groups. Therefore, they are not included in *A Tentative List of Tulip Names*, which is published by the R.H.S. at a nominal price of 1s. 3d. post free.

British Mycological Society.—The thirty-third Autumn Fungus Foray and General Meeting of this Society will be held at Bristol from Monday, September 30, to Saturday, October 5. Accommodation is available at the Elmdale Hotel (15s. per day), and the Lyndale Hotel (12s. 6d. per day), but members are advised to book their rooms at once. Applications should in each case be made to the Manager, mentioning the British Mycological Society, and stating whether a single or double room is required. The headquarters for the meetings and exhibits will be at the University and microscopes will be available. Members who intend to be present are particularly requested to inform the Secretary not later than Monday, September 23, and to state whether they wish to be included in the party visiting Long Ashton Research Station on Wednesday, October 2. The programme for the gathering is :—Monday, September 30: 8 p.m., Professor and Mrs. Darbishire invite members to coffee; 8.45 p.m., Council Meeting. Tuesday, October 1: Start from headquarters at 10 a.m., by chars-a-bancs to Cleve Combe, Ball Wood and Corporation Wood; tea probably at Wrington; 8.45 p.m., Annual General Meeting. Wednesday, October 2: It is hoped to arrange a visit to Long Ashton Research Station in conjunction with the visit of the Imperial Mycological Conference. Those who wish to join the party should inform the Secretary. Other members will visit Long Ashton Estate Woods; conveyance probably by chars-a-bancs; 8.45 p.m., Presidential Address entitled "Fungi Exotici; Past Work and Present Problems." Thursday, October 3: Start about 11 a.m. on a visit to Blaize Castle Woods; 8 p.m., Mr. Ramsbottom will deliver a popular open lecture, to the Bristol Naturalists' Society; the lecture entitled "The influence of Fungi on Life in General," will be given in the Museum lecture-theatre, by kind permission of Dr. Bolton. Friday, October 4: Start about 11.30 a.m. for Leigh Woods; 8.45 p.m., comments on the finds of the week by Mr. Carleton Rea.

Begonia Fields in Belgium.—Dutch horticulturists have long recognised the value of propaganda in attracting large numbers of tourists of all nationalities to see the wonderful fields of bulbs which are such a well-known and popular feature of the Dutch landscape in the spring. Begonia-growers in the Ghent district of Belgium are beginning to be aware that the Begonia fields present at least equal attractions to visitors, and are considering ways and means of undertaking some sort of joint publicity which will have the effect of attracting tourists to their nurseries. The initiative is being taken by the indefatigable Comte de Kerchove and already two excursions have been arranged, for September 8 and 15, to the principal Begonia nurseries. The journeys will be made by motor-car, and each party will be accompanied as guide, by a member of the organising committee.

Bagatelle Park, Paris.—In view of the fact that the fee for admission to the Royal Botanic Gardens, Kew, has lately been abolished, it is interesting to learn that the Paris park authorities have decided that for admission to Bagatelle Park, Paris—which has hitherto been open free to the public—a fee of two francs shall be payable on Mondays, Tuesdays, Wednesdays and Saturday mornings, and of five francs on Fridays. There will still be free entry on Thursdays, Sundays, public holidays and Saturday afternoons. Bagatelle, which was formerly a royal estate, is now the scene of the annual trials of new Roses, which are sent from a number of different European countries. English and Irish Roses are always well in evidence, and gain a good proportion of the awards.

Mr. D. MacGregor.—After twenty-five years' service, Mr. D. MacGregor has retired from his position as Superintendent of the Shanghai Municipal Parks and Gardens, and recently returned to Scotland. Mr. MacGregor has accomplished a wonderful task, for when he went to Shanghai gardening there was in its infancy, and the public parks embraced only a few acres; the many fine parks, recreation grounds and open spaces which Shanghai now possesses speak eloquently of Mr. MacGregor's skill as a designer and administrator. During his period of office he was responsible for the introduction and acclimatization of many plants which are now commonly grown out there; this work being conducted in the Park Nurseries, which embrace about forty acres, and were designed by Mr. MacGregor; twelve acres of this area were laid out as an experimental ground for the study of the cultivation of farm and garden crops under local conditions, and the selection of suitable types was carried out to the benefit of the agricultural and horticultural community. Many were the expressions of appreciation and good fellowship which marked Mr. Mac Gregor's retirement from the post which he had filled so admirably. Before leaving Shanghai, he was presented with one of the special medals struck to commemorate the funeral of Dr. Sun Yat Sen, First President of the Republic of China, in recognition of his services in connection with the designing of Memorial Park, Nanking, which embraces about 10,000 acres; he was also presented with a silver shield by his colleagues on the Memorial Parks Design Committee. Members of the Gardening Section of the British Women's Association at Shanghai presented Mr. MacGregor with an engraved antique bronze flower vase, while members of the Shanghai Horticultural Society, of which Mr. MacGregor was Hon. Director for twenty-four years—1905 to 1929—presented him with a handsome silver cup on an inscribed Blackwood stand. An account of Mr. D. MacGregor's horticultural career appeared in our issue of August 16, 1924 (p. 106).

MR. D. MACGREGOR.

London Gardens Guild's Exhibition.—The Exhibition of the London Gardens Guild, on August 30 and 31, was the first this Society has held in the R.H.S. Hall. The outstanding features of the display were corporate groups from horticultural societies and from municipalities in the London area. These, with some very fine trade groups, made a bright splash of colour. Of the displays set up by municipal authorities, that from Camberwell was awarded the first prize, with Bermondsey a very close second. In the corporate displays from local horticultural societies, Bermondsey and Camberwell were respectively first and second, both showing well-arranged groups of hardy herbaceous plants, with Lilium auratum as the *piece de résistance.* Other classes comprised children's displays from school gardens, in which class a Kensington school gained first prize; some very tastefully arranged bowls of flowers and foliage; groups staged by members of Post Office and other Civil Service horticultural societies, and five classes open only to persons residing within five miles of London Bridge. There were photographs of gardens which were awarded prizes in the 1929 Garden Championships, together with displays of flowers grown in them. On Saturday, August 31, there was a distribution of exhibition awards by Lady Seton, which included trophies won in the All London Gardens Championship and the cups awarded in the Brighter Petrol Station contest.

Importation of Fruit Stocks into United States.—The Ministry of Agriculture and Fisheries has been informed it has been decided that Mahaleb Cherry, Myrobalan Plum and other fruit stocks, such as Fig, Nut, Persimmon, etc., which have been imported hitherto in relatively small numbers, will be excluded from entry into the United States on and after July 1, 1931.

Forthcoming French Horticultural Exhibitions.—An exhibition of fruits of all kinds, Orchids, stove plants, Roses, Dahlias, and other garden products and features will be held at Clermont-Ferrand, France, from September 19 to 23. From October 3 to 7, there will take place at Grenoble an exhibition embracing horticulture, agriculture, forestry and biology. The show, which is being held under the auspices of the local authorities, will be in the new exhibition park and buildings created in 1925. The Haute-Vienne Horticultural Society is organising an exhibition of Chrysanthemums and other horticultural products, to be held at Limoges from October 19 to 24, for which the President of the Republic has promised to give a prize. At Lyons, the proprietors of the P.L.M. Railway are to organise, from November 7 to 9, a Forestry Congress, which will study particularly the question of carboniferous products from wood. The Ministry of Waters and Forests is taking part in the organisation of the Congress, which will be accompanied by an exhibition of industries connected with forestry.

The "Botanical Magazine."—The recently published Part I, Vol. CLIII (1927) of Curtis's *Botanical Magazine* contains coloured plates and descriptions of Crinodonna Corsii (t. 9,162), Picea omorika (t. 9,163), Eustephia Pamiana (t. 9,164), Rhododendron haematodes (t. 9,165), Primula vulgaris var. heterochroma (t. 9,166), Carduncellus multifidus (t. 9,167), Corokia macrocarpa (t. 9,168), Salvia superba (t. 9,169), Epidendrum pumilum (t. 9,170), Cotoneaster glaucophylla forma serotina (t. 9,171), and Acacia extensa (t. 9,172). Crinodonna Corsii is a generic hybrid, and appears to have been produced simultaneously in Italy and California. It was described—in *The Gardeners' Chronicle* for January 15, 1921—by Dr. Attilio Ragioneri, of Castello, near Florence, who raised it by crossing Amaryllis Belladonna and Crinum Moorei, the former being the seed parent. Mr. F. Howard, of Los Angeles, California, made the same cross, the first of the four plants which he secured flowering in 1915, but the flowers were badly formed. The second plant to flower, however, produced blooms which corresponded with those of Dr. Ragioneri's plant. Mr. Howard's cross was named Amarcrinum Howardii, which name, of course, is superseded by Crinodonna Corsii. A figure of Mr. Howard's plant was published in *Gard. Chron.* for November 21, 1925, together with comments upon it by Mr. J. Coutts, and these are quoted at length in the *Botanical Magazine.* Picea omorika, the Serbian Spruce, was discovered in 1875 by Professor Joseph Pancic, in the Tara Planina, on the right bank of the Drina. It was introduced to cultivation in 1881, and has since become fairly widely distributed in Europe. It has been figured and described in this journal several times, the first occasion being in 1884 (Vol. XXI, pp. 308, 309, Fig. 58). Eustephia Pamiana is a recent introduction among Amaryllids, the plant figured being one raised by Major A. Pam, of Wormley Bury, Broxbourne, from bulbs received from Tucuman. It is quite distinct from the other members of the genus, its flowers being half red and half green. Mr. George Forrest is responsible for the introduction of the very striking, crimson-flowered R. haematodes to this country, although it was first discovered by Père Delavay in 1885, on the Tali range, Yunnan. It is described as deserving to receive "every consideration on account of its beauty and its hardiness under conditions which provide for partial shade and an ample supply of water." Primula vulgaris var. heterochroma is the Oriental Primrose; the illustration is the white form, but the colours range from pure white to yellow, blue, or rose-purple. Carduncellus multifidus is an attractive-flowered North African species, with lavender-violet flowers; the plant illustrated was introduced from Algeria by Mr. E. A. Bowles a few years ago. The attractive Corokia macrocarpa is endemic in the Chatham Islands, where it was discovered by Dr. E. Dieffenbach in 1840; Mr. G. W. E. Loder has grown it successfully in his garden at Wakehurst Place, Ardingley, Sussex, for more than ten years. The name of Salvia superba is adopted by the *Botanical Magazine*, for the popular summer-flowering border plant known variously as Salvia nemorosa, S. nemorosa var. virgata and S. virgata var. nemorosa. It is suggested that it is a hybrid between S. silvestris and S. villicaulis; it is, apparently, sterile, and has never been recorded in a wild state. Epidendrum pumilum, from Costa Rica, is an attractive little Orchid which was introduced from Costa Rica by Messrs. Sander and Co., about 1890. Considerable confusion has existed as to the identity of the Chinese Cotoneaster raised at Wisley as C. glaucophylla and later identified as C. serotina. It is undoubtedly one of the most attractive of the Cotoneasters, being handsome in flower, fruit and foliage, and it has now been identified as C. glaucophylla forma serotina. Acacia extensa, from the south-west corner of West Australia, is a plant of somewhat straggling habit, but it compensates this by producing a wealth of brilliant yellow blooms; at Kew it is grown in the Temperate House, being too tender for the open garden.

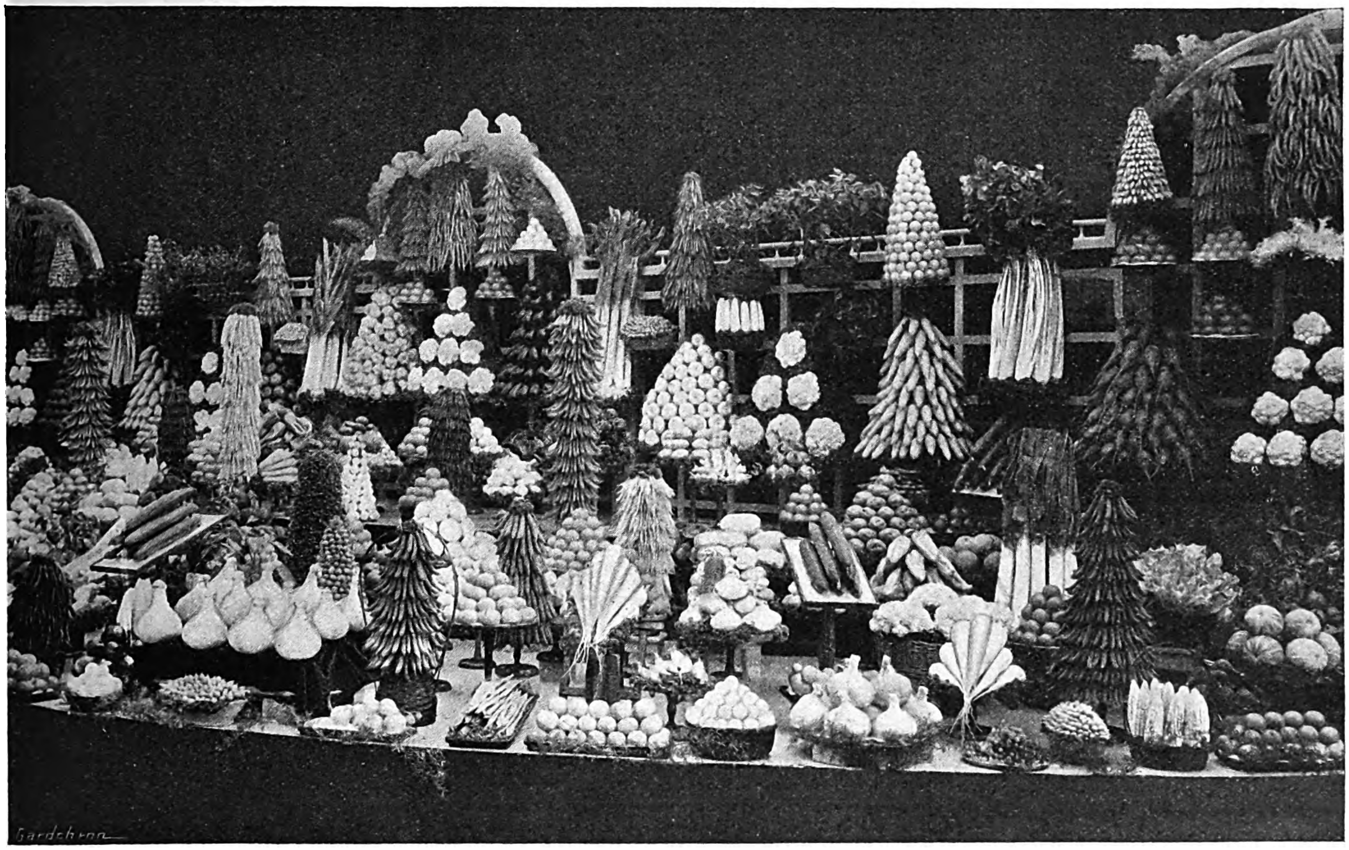

FIG. 85.—SOUTHPORT SHOW: A GRAND EXHIBIT OF VEGETABLES STAGED BY THE HON. VICARY GIBBS (GR. MR. E. BECKETT).
(see p. 193.)

Antwerp International Horticultural Exhibition.—A good deal of the preliminary work, preparation of the ground in front of the hall,—planning of the gardens, etc.—has now been accomplished, and intending exhibitors at the International Exhibition to be held in Antwerp in 1930 are being invited to go over and inspect the various sites available. The first of the sectional or "seasonal" exhibitions is to coincide with the opening of the World's Fair, but up to the present we have seen no statement as to the actual date. It will probably be in April. Another seasonal exhibition is to comprise Roses, Sweet Peas, and Carnations, and will last from June 23 to 26; cut flowers, Dahlias, and market garden produce will be shown from September 13 to 16, and Chrysanthemums and fruits from October 13 to 15. Each of these special shows is to be arranged by an expert, the four mentioned above being undertaken by M.M. John Juchem, Ed. Cools, Josse Goris and G. Wachtelaer, respectively.

Appointments for the Ensuing Week.—MONDAY, SEPTEMBER 9: National Chrysanthemum Society's meeting. TUESDAY, SEPTEMBER 10: Royal Horticultural Society's Committees meet; Jersey Gardeners' Society's meeting. WEDNESDAY, SEPTEMBER 11: National Dahlia Society's Show; Royal Caledonian Horticultural Society's Exhibition (two days); Sheffield Chrysanthemum Society's lecture. THURSDAY, SEPTEMBER 12: Faversham Chrysanthemum Society's meeting. FRIDAY, SEPTEMBER 13: National Rose Society's Show (two days); Royal Horticultural and Arboricultural Society of Ireland's meeting; Leeds Paxton Society's visit to Leeds Allotment Show; Manchester and North of England Orchid Society's meeting. SATURDAY, SEPTEMBER 14: Leeds Paxton Society's Chrysanthemum Show; Royal Horticultural Society of Courtrai's (Belgium) International Exhibition (three days).

"Gardeners' Chronicle" Seventy-five Years Ago.—*Victoria Regia.*—It may not be uninteresting to know that this fine Water Lily can be grown in perfection in a much smaller tank and house than many suppose it possible for it to thrive in. It may now be seen in the most robust health, and flowering profusely at Flitwick Manor, Bedfordshire, the seat of Mr. Brooks. The Gardener, Mr. Hewetson, had a seedling plant of it sent him a distance of more than one hundred miles, on April 12 last he planted it as soon as he received it in a slate tank, nine-and-a-half feet long by nine feet wide, and three-and-a-half feet deep, in a compost of strong turfy loam and decayed cow manure, and I have not seen any plant of this Lily growing so luxuriantly, or flowering so freely. The leaves measure five-and-a-half feet in diameter, many of them hanging over the sides of the tank. Other aquatics are growing in similar tanks with equal vigour, and are flowering abundantly. At present there are many beautiful flowers open on Nymphaea spodiana (?) and others are showing for flower. All were planted in the same compost, and have had comparatively but little fire-heat. *J. F., Luton Hoo Park. Gard. Chron., September,* 9, 1854.

Publications Received.—*Jones' County Court Guide,* by Charles Jones, revised by J. Prys Williams; pp. 391; Messrs. Effingham Wilson, 16, Copthall Avenue, E.C.2., price 10s. 6d.—*A Tentative List of Tulip Names,* pp. 80; The Royal Horticultural Society, Vincent Square, S.W.1, price 1s.—*Curtis's Botanical Magazine,* Part I, Vol. CLIII; Messrs. Bernard Quaritch, Ltd., 11, Grafton Street, W.1., price 17s. 6d. net.

The Week's Work.

THE ORCHID HOUSES.

By W. Gilden, Orchid Grower to Dr. F. Craven Moore, Duckyls Park, East Grinstead, Sussex.

Odontoglossums.—The cool-growing members of this genus, together with Cochliodas, and the many hybrids derived from these two, thrive well when grown in a cool house shaded from direct, bright sunshine, with ample ventilation, and moist surroundings. A buoyant atmosphere should be maintained at all seasons, and during the summer months no fire heat is necessary, unless cold, wet spells of weather occur, when a little warmth in the pipes for a short time will generally help to keep the atmosphere sweet (with plenty of bottom ventilation) and prevent the temperature falling below 55°. The top ventilators should be opened on all favourable occasions, increasing the amount of air admitted during moist, warm weather, but cold draughts should be avoided. During the winter a minimum temperature of 50° should be aimed at, but no harm will accrue should the temperature fall a few degrees below this during very severe weather, rather than use excessive fire heat. It should, however, be realised that many of the occupants of this division are making their growth through the winter months, and should be kept growing steadily, and this requires a minimum of over 48°, when the necessary fresh air is allowed. This year, during the spring and early summer months, the weather conditions were not favourable to the growth of these cool-house Orchids; several weeks of cold, dry, east winds in the spring, followed by the hot, and still very dry, spells of summer weather, made it very difficult to maintain suitable growing conditions for the plants, which suffered a little in consequence. During the past month the weather conditions have been more favourable to the cultivation of these popular Orchids; the moister atmosphere and more subdued light, together with the cooler evenings, have been most beneficial to them, and they have responded quite readily to them. Plants that flowered during the spring and early summer months are now making fine growth.

Repotting.—Odontoglossums that are in need of repotting may be attended to as the required stage is reached. New roots are generally produced in quantity just as the young growths are beginning to form pseudo-bulbs, and this is the best stage at which to repot, provided the soil is not sour, in which case it is best to repot directly the new roots commence pushing forth, when the plants establish themselves more quickly than if done at an earlier stage. Any plant in this stage that is in need of fresh compost, or a larger receptacle, should be turned out and all old compost and decayed roots removed, especially the decayed portion in the centre of the ball. Any leafless back pseudo-bulbs should be cut off, leaving two or three to each lead. A little powdered charcoal should be dusted on the severed portions, to prevent decay. Well-drained pots of a suitable size should be used; it is safer to use pots on the small side than to over-pot them, which often results in decayed roots during the winter should they remain moist for a long period. Keep the bases of the pseudo-bulbs about level with the pot-rim; it is not advisable to bury any pseudo-bulbs or rhizomes beneath the compost, which should be pressed in firmly around and among the roots. A suitable rooting medium consists of equal parts of Osmunda and soft A.1. fibre, and one part chopped Sphagnum-moss; a little extra fresh moss may be used on the surface. Water should be afforded very sparingly until the roots are well established in the soil, strict attention given to shading, and the surroundings and pots sprayed in suitable weather to encourage root action.

Pleiones.—Various members of this genus are completing their growth and will require ample supplies of water at the roots until this is accomplished; any feeding with liquid manure should be discontinued when the leaves are fully matured. As the leaves begin to die off water should be withheld gradually until they fall, when only a limited quantity at rare intervals will be needed until the flower buds appear, when the supply should be slightly increased until the blooms are fully developed, care being taken to avoid any moisture collecting in the young growths, which quickly decay if allowed to remain in that condition.

HARDY FRUIT GARDEN.

By Henry H. Cook, Chief Assistant Lecturer, Reading University Horticultural College.

Early Dessert Pears.—Those who have not grown Pear Laxton's Superb should make a note of it, as it is, undoubtedly, the best-flavoured Pear we have at the end of August. It crops regularly at an early age, and the trees are vigorous and healthy. In common with most early Pears, the fruits should be gathered and eaten before they are quite ripe. Clapp's Favourite is an early September variety of only moderate flavour. Williams's Bon Chrêtien is to well known to need any description, beyond that it is fertile and prolific, and should be gathered before it turns yellow. Dr. Jules Guyot is very similar to Williams's Bon Chrêtien in appearance and quality, and is a regular cropper. Beurré d'Amanlis bears fruits of large size and of good flavour. The skin is a bright green, slightly bronzed on the exposed side, the whole turning yellow with maturity. It bears consistently and is very hardy. Marguerite Marillat is another September variety of quite good flavour. The fruits are very large, orange-yellow with a red flush and patches of russet. Its growth is strong and upright, and it bears freely in warm and sheltered situations. Conference is a dessert Pear of good quality, its fruits being medium in size and very long-necked, yellowish-green in colour and much russeted. Early Pears should not be left too long on the trees and when stored, even for a few days, they decay at the core or become mealy. Examine the trees regularly and gather a few of the more advanced fruits before they are quite ripe. In that way the season of use will be lengthened and the fruits better flavoured.

PLANTS UNDER GLASS.

By T. Pateman, Gardener to Sir Charles Nall-Cain, Brocket Hall, Hertfordshire.

Nerines.—These greenhouse bulbous plants are now pushing up their flower spikes, and from now onwards they should be well exposed to the light in a cool greenhouse. At this stage of cultivation the plants should not be overwatered, but when the flower spikes are moving and the plants are making their foliage, every encouragement should be given them to make as much growth as possible. Nerines resent frequent potting but appreciate an occasional top-dressing of good fibrous loam, leaf-soil, and some decayed, dried cow manure. Some of the surface soil may have to be removed before the top-dressing is applied. Considerable progress has been made in the raising of new hybrid Nerines in recent years, but quite one of the most useful is Nerine Fothergillii var. major.

Annuals.—There are a number of annuals suitable for pot work and for producing a fine display of flowers during the spring. Among the best are Clarkias and Schizanthuses. If sowings of these are made now, the resulting plants should make good flowering subjects by next April, while a second sowing made a month hence will continue the display until June. It is important to remember that cool treatment should be given at all stages of growth, and that the plants' greatest enemy is dampness and coddling. Sow the seeds thinly in boxes or pans, in a light, open compost, and raise them in a cold frame. So soon as the seedlings can be handled with safety, prick them out singly, or three in a three-inch pot. The single plants may be grown on into six-inch pots, while the groups may be potted on undisturbed into larger receptacles. The plants should be pinched back about twice to induce bushy growth. Careful watering and staking of the plants is essential to produce shapely specimens.

Swainsonia galegifolia (coronillaefolia).—This species and its varieties purpurea and alba, are useful for training up pillars in the greenhouse, and are also attractive when trained around sticks or wires to form specimen plants. They grow very quickly and, provided they are frequently supplied with applications of liquid manure, will flower for a considerable period, even when the roots are confined to receptacles of only moderate size. Cuttings of young shoots taken now will form good plants for flowering next season, and will root freely if inserted in light, sandy soil, the cutting pots being placed on a mild hot-bed. This plant will grow in almost any soil, but a mixture of loam, leaf-mould and sand will be found the most suitable.

Humea elegans.—Make another sowing of this graceful plant towards the end of the present month. Cultural details were given in a previous calendar.

FRUITS UNDER GLASS.

By F. Jordan, Gardener to Colonel Spender Clay, M.P., Ford Manor, Lingfield, Surrey.

The Orchard House.—The early and mid-season varieties of Peaches and Nectarines will be over, and very late ones swelling crops freely. The management of these until the crops are cleared will include abundant ventilation, syringings on fine mornings, without wetting the fruits, and careful watering—those nearly ripe with plain water. Late Pears, Apples and Plums should have light stimulants, both liquid and solid, so often as required. If well cropped, the trees will be making very little growth, otherwise all laterals should be kept pinched closely to let in light and air, and to mature the flower buds, which should be ripe by the end of September. When the fruits approach ripeness they cannot be handled too carefully, as the slightest pressure sets up fermentation and the flavour is destroyed; many good growers do not exercise half enough care in gathering and packing fruits.

Melons.—Late plants should now be hastened forward with all possible speed by closing the house early to trap sun-heat, and a more or less moist atmosphere maintained, according to the state of the fruits. If still swelling, the surface of the bed and the floors may be well syringed with tepid water at closing time, but on no account should the foliage or stems be wetted, as moisture about the collars now that the nights are longer and colder, is sure to result in canker. Early closing will greatly economise fire-heat, but the time has now arrived for warming the pipes to maintain a proper amount of heat, with a little night air, and to prevent an accumulation of stagnant moisture in the lower part of the house. Watering will also require careful attention, and here the advantage of having late plants in pots will be apparent, as all the roots are close to the sides, a position favourable to watering without wetting the collars of the plants. A little warm liquid manure may be given until the fruits have attained full size and are netting freely, but of two evils, it is better to under-feed than to try and force the fruits beyond their normal size, especially at this late period, as medium-sized Melons will keep sound longest and carry the best flavour. Another important matter is that of bottom-heat, which should not be overlooked; there is no period when a sharp bottom-heat is of more advantage than at the finish. Frame Melons will now be nearly over, but where fruits still remain unripe, the bottom-heat material should be examined carefully and renovated if necessary. Hot-water pipes have spoiled the majority of modern gardeners for frame culture, but with improved varieties a higher percentage of first-class fruits can be grown by renovating the linings of the hot-beds regularly, by early closing to entrap sun-heat, and careful protection with matting before nightfall.

THE FLOWER GARDEN.

By R. Findlay, Keeper of the Gardens, R.H.S. Gardens, Wisley, Surrey.

Sowing Lawns.—On light soils the best season to sow new lawns is at the end of August or as early in September as conditions permit. The soil is warmer at the end of summer and early autumn than during spring, and the autumn rains and heavy dews are conducive to good germination. Grass sown now has ample time to become well established before the cold weather sets in; it has also been proved that seedling weeds are not nearly so troublesome where lawns have been sown during early autumn as on those where the work has been left until spring. Prepare the site by thorough digging, and manuring if the soil is poor, as much of the future results depends on the initial preparation. The seed-bed should be prepared by treading the ground until it is perfectly firm and level, and when walked on hardly shows the imprint of the foot. To produce a close, dense turf within a year under normal conditions, at least one ounce of seeds should be sown to the square yard, but this amount can be doubled if it is desired to have an early result. Sow seeds of the finest quality only.

Border Carnations.—Those plants which were layered early in the season should now be ready to plant in their permanent beds. To have the plants well established in their new quarters before severe weather sets in is one of the chief points the cultivator of these hardy plants should aim at. Carnations like an open, sunny position and deeply worked soil, which should be moderately rich, and contain a good proportion of lime-rubble and soot. Pinks also should be planted without delay. On some soils all that is necessary with these is to lift the old roots and divide them into small pieces and replant where they are to bloom. Cuttings or pipings of Pinks that were inserted in frames in July ought now to be planted out.

THE KITCHEN GARDEN.

By W. G. Staward, Gardener to Lady Margaret Ryder, Knowle Gardens, Dunster, Somerset.

Cauliflowers.—To secure good, early heads of Cauliflowers next spring, it will be necessary to sow seeds now, and to make a further sowing about a fortnight later. Sow the seeds thinly in a sheltered spot in the open garden, or in boxes. So soon as the seedlings are large enough, prick them out about four inches apart into frames where plenty of air can be given to keep the plants free from dampness. A number may be pricked into four-inch pots for potting on to produce a supply in early spring, but on no account should the plants be coddled; a free circulation of air should be maintained on all possible occasions.

Onions.—Spring-sown Onions will now be ready for gathering, this work being done preferably in dry weather. For this operation place the Onions in full sunshine for a few days to dry them thoroughly, and turn them over every day to ensure they become thoroughly dry before removing them to the store room, which should be airy and dry. They may be bunched and hung up on the rafters. The ground from which the Onions have been cleared may be dug and planted with spring Cabbages, Flower of Spring and Harbinger being two reliable varieties for this purpose, allowing eighteen inches between the lines and twelve inches from plant to plant. Later Onions should be examined and the tops bent over so as to help the bulbs to swell to their fullest extent and quicken the ripening of them; but so soon as they have ceased swelling and are noticed to be on the wane, lift the bulbs with a fork and dry them off.

Lamb's Lettuce.—This salad,—Corn Salad, as it is frequently called—makes an additional autumn and winter salading. The seeds may be sown now in drills, in the same way as for Lettuce, but it is not necessary to thin the seedlings so severely. This plant is very hardy, as a rule, and will generally continue to produce plenty of fresh leaves throughout the winter months.

General Work.—Should further sowings of Spinach be necessary, sow the Prickly-leaved type on any vacant ground. If there are not enough Lettuce and Endive plants to maintain a good supply, further sowings of these salads may be made; also Model White and Veitch's Globe Turnips, for nice Turnips can still be grown before the ground becomes too cold.

FOR NORTHERN GARDENERS.

By John Hill, Gardener to Andrew Arthur, Esq., Rosemount, Monkton, Ayrshire.

Vegetables. — Spring Cabbages which were sown in July should now be planted on the most favourable piece of ground possible. In most districts a border facing due south is necessary, and if ground from which Potatos or Peas have been cleared is used, surface cultivation will suffice. Being of compact growth, twelve inches apart in rows twenty inches apart is quite a good spacing. Care should be taken to keep off slugs for a week or two until some growth has been made, the best plan being to poison the pests with Paris green administered on bran, of which they are very fond. When established, a collar of sifted coal ashes placed around each plant is of great service in steadying the plant, keeping the stem dry, and warding off slugs as well. Mid-season Potatos should now be ready for lifting, and the first dry day should be chosen for this work. Examine the tubers as they are lifted, removing all diseased or small specimens, and leave the sound crop to dry for an hour or two before placing them in pits or a cool shed. A pit or clamp is undoubtedly the best place for storing Potatos, and should not be too deep or broad. Six inches deep by eighteen or twenty broad will allow of sufficient bulk to ensure good keeping. Clean, drawn straw should be placed next the tubers and covered with a six-inch layer of soil, well beaten, to finish off.

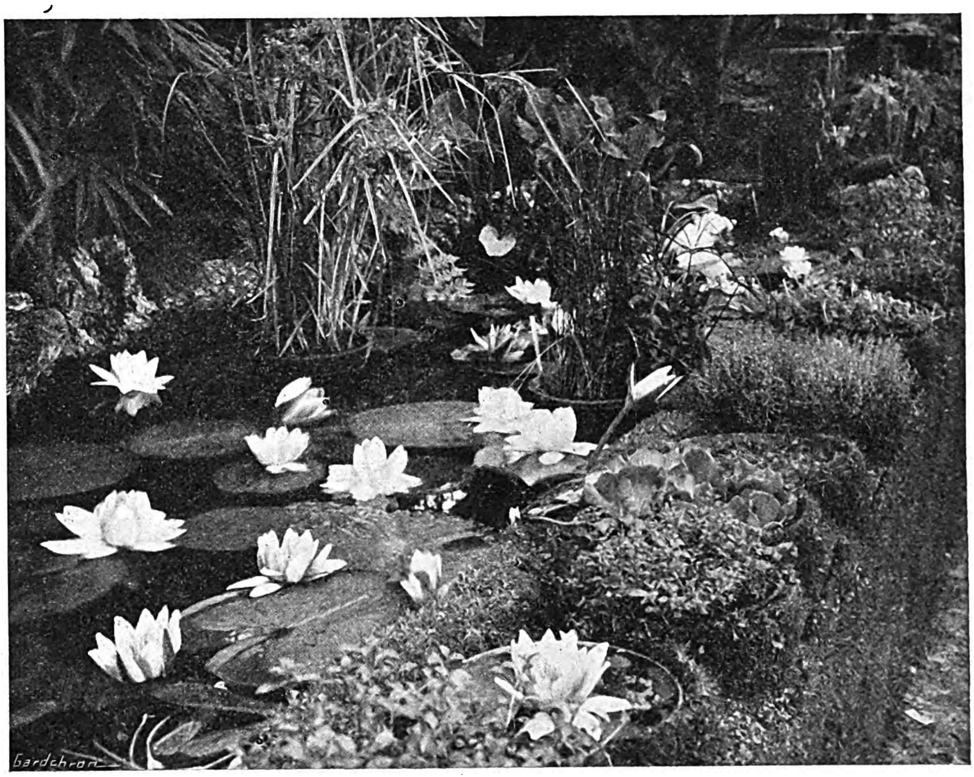

FIG. 86.—SOUTHPORT SHOW: MR. AMOS PERRY'S EXHIBIT OF AQUATIC PLANTS.

(see p. 193.)

The Rock Garden.—When seeds have been saved, all old flower heads should be removed, and any overlapping growths cut away. Some gritty soil should be carefully worked with the fingers among the dwarfer subjects, and the ground stirred with a fork in other cases. Where dwarf Heaths are grown they soon get leggy and overgrown, and if this occurs they should be pegged down and the bases of the stems covered with soil; if this is of a peaty nature, so much the better, but so long as lime is absent it matters little what is used. If this is carefully done, the appearance of the plants will be much enhanced, and their life lengthened considerably. Tree Heaths, as they attain size, should be supplied with stakes, as many of them are very brittle and are often damaged badly by wind or during falls of snow.

Malmaison Carnation Layers.—These should now be ready for potting, and should be severed from the parent plants several days before this operation. Two-inch pots are best for this purpose, and as the compost was in large measure leaf-mould, it should be shaken or washed off the roots, while if the latter are too long to go into the pots without twisting, they should be shortened with a sharp knife. Fine soil, consisting chiefly of good loam with a little sand, lime-rubble and burnt earth added, is the best compost at this stage. Pot each layer only so deeply as to hold it erect, and firm the soil by tapping the pot on the bench. Place the potted layers in a close, cold frame and keep them sprayed and shaded during the day, admitting air at night only for the first week, after which they may receive all the light and air possible.

Chrysanthemums.—Every plant which is well set with buds should be housed, as frosts are quite likely to occur and generally do before mid-September. If housing is impossible, screens will provide sufficient protection for another month, unless the weather be very wet.

Strawberries.—Cultivate between the rows of recently-planted Strawberries and remove all runners as they appear. If further plantings have to be made for next year's fruiting, no time should be lost in getting the work done, as growth will soon slow down, and poor results follow late planting.

INDOOR PLANTS.

REHMANNIA HENRYI.

I KNOW not to what degree of hardiness this plant may lay claim, as all the examples within my experience have been grown in a cold house, either planted out or in pots; the large, somewhat Gloxinia-like flowers are little short of pure white and are splendidly foiled by the dusky, green foliage.

A much dwarfer plant than the well-known R. angulata, R. Henryi is even more beautiful, I think, and, apparently, is a "good doer" in a well-drained mixture of loam and leaf-soil. It is a plant of distinction and is possessed of high merit as a subject to include in a collection of choice and interesting cool greenhouse plants, and what is more interesting than a series selected from the numerous plants which fall just short of hardiness; a well-equipped structure with provision for a little heat during very severe weather, may be rendered a veritable treasure house at little expense.

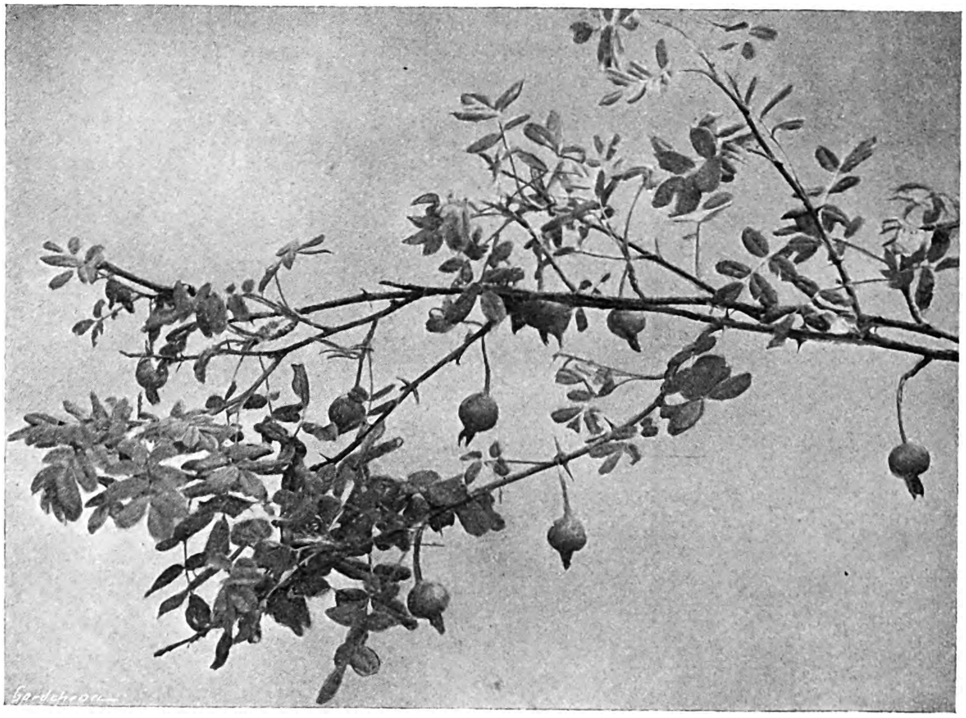

FIG. 87.—ROSA SERICEA: FRUITING SPRAYS.

MORAEA BICOLOR.

THE somewhat large, lemon-yellow or buff-coloured flowers of Moraea (Dietes) bicolor are striking rather than beautiful; the intensely dark spots, brownish-black in colour, accentuate the distinctive qualities of the blossoms if they do not invest them with additional beauty, and the ample, Iris-like foliage provides grace and charm to a well-grown group.

A native of South Africa, this Irid is an ideal plant for the cold greenhouse and will excel under similar treatment to that afforded Ixias; I recently saw a strong group of M. bicolor in full flower, the numerous flower spikes, eighteen inches to two feet in height, arising in delightful fashion from the tuft of Iris-like leaves; planted in rockwork within the greenhouse, the plant created a pleasing feature and evoked considerable interest, and when so grown, a colony may remain undisturbed, with decided advantage, for two or three years.

ANIGOZANTHOS FLAVIDA.

THE tall and branching inflorescence of this plant is most distinctive, and will invest a cool greenhouse with a feature of unusual interest; the flowers are parti-coloured, yellow and green, quite decorative, but not nearly so showy as those of the varietal form, A. f. var. bicolor, of scarlet and greyish-green colouring.

These somewhat uncommon greenhouse herbaceous perennials succeed admirably in a mixture of one part loam to three parts of peat; they are happiest when planted out, although pot-grown plants are quite desirable. Division of the roots in spring affords a ready means of increase, and an ordinary cool greenhouse will provide the ideal environment.

Native of Australia, A. flavida was introduced in 1808, and A. f. var. bicolor, from the Swan River district, in 1837. These summer-flowering subjects should certainly be grown where interesting and uncommon plants of decided beauty are cherished. *Ralph E. Arnold.*

ALPINE GARDEN.

GENTIANA PROLATA.

THIS charming member of the Asiatic group of Gentians has been at its best here during the past few weeks, and is only now beginning to pass into the disreputable, but highly satisfactory stage of fat, brown seed pods, or rather, fat seed pods within the encasings of dead flowers.

It is quite distinct from its nearest confrères among the Asiatics, *i.e.*, G. Farrerii and G. sino-ornata, while combining something of both of them in its appearance.

It is much earlier flowering than either of them, G. Farrerii is just commencing to open its large, Cambridge-blue trumpets as the flowers of G. prolata decay, and after G. Farrerii we shall have G. sino-ornata until almost Christmas, so it all helps in the succession of flowers, especially just now, when things are a wee bit dull in the rock garden.

As we are grateful for anything that gives a bit of colour, how much more should we value this Gentian which seems to be as beautiful as it is virtuous.

Virtue in a plant, of course, consists in its willingness to "do" with us, and from my two-years' experience with it I should say that G. prolata is going to thrive as well as G. sino-ornata (I wish I could write the same of G. Farrerii, which grows quite well, but never with the healthy abandon of "sino," as we call it). We have an old stone sink planted with my original seedlings, which I owe to the generosity of the owner of a famous "Gentian garden" in Scotland; they were planted in a rich mixture of leaf-mould, silver sand and broken sandstone in equal proportions, and they never looked back, but went ahead with a generosity of growth that was beautiful to witness.

Last year I was blessed with but one flower (from which I saved twenty-five seeds, all of which germinated), but this year it has been prodigal of its Cambridge-blue flowers.

I find it very hard to describe colours and almost always have to coin words or phrases to serve my ends and chance whether they convey the same meaning to other folks, so, I may state that the blue of G. prolata seems to me to be a "sybilant blue." I wonder if that will convey anything to anybody? It is a little paler than G. Farrerii, and has not such distinct throat markings; the flowers are smaller but open well, and it is a truly beautiful sight when, as was the case on my sink, there were some two hundred flowers open together.

The habit of growth is somewhat similar to G. sino-ornata, but smaller, stiffer and a darker green, the trailing stems being numerously clothed with the small, sharply-pointed, dark green leaves. It flops around like its larger cousins and the trailing stems will root as they go, with but the slightest encouragement.

As regards propagation I think it is going to be very easy, I have tried seeds, division and cuttings, the latter inserted at various times during the season, and all these methods have met with one hundred per cent. success. Some I treated as we treat G. sino-ornata and split them up when the first growth of the year was about half-an-inch long; these were planted straight out in the granite "Treasure Box" and have all grown and are now flowering well.

In a few years' time I think it will be as well known and grown as G. sino-ornata, itself, which latter I should say surely holds a record for rapid growth of popularity; it seems but yesterday that we were treasuring our few wee pieces, and now we speak calmly even of our tens of thousands. *Will Ingwersen, The Birch, Sharpthorne, Sussex.*

HARDY FLOWER BORDER.

PLATYCODON GRANDIFLORUM VAR. MARIESII.

ALTHOUGH some authorities regard it as a species the plant known in gardens as Platycodon Mariesii appears to be a Japanese form of P. grandiflorum. Indeed, the Kew *Hand List* unreservedly places the whole of the family under that one specific name. There can be few plants in cultivation, especially among the older introductions, whose great merits have been so over-looked as have those of the Balloon-flower. There may be some difficulty with some of the varieties, including the type species, just as there is with its ally, Ostrowskia. But that difficulty does not exist with the subject of this note, not at any rate to an extent sufficient to provide a reason for its exclusion from so many gardens.

I have never had any trouble with P. g. var. Mariesii. Planted in a deep, stony loam, which is never very dry or very wet, a colony of plants covering a couple of square yards has been an unqualified success for years. This variety does not grow above a foot or so. The stems are amply furnished with the rich green, egg-shaped, sharply-toothed leaves. They stand erect—no small concession this in such plants—and bear at each of the tips of their branching summits a loose cluster of the magnificent blooms. These flowers are produced in great abundance from July to autumn, the bulging, balloon-like buds expanding their broad, pointed segments to a diameter of three or four inches. These blossoms are of a fleshy texture with a satiny gloss and while the colour is usually a bluish-purple, rich and clear, the tint varies to powder-blue and starch-white, all kinds being more or less veined with a darker shade. P. g. var. Mariesii is entirely herbaceous, the foliage assuming a brilliant yellow before the stems disappear. Although the spring growth comes with the slugs, these pests do not attack them, at least that is my experience in a slug-infested garden, and the plant is unquestionably hardy. Since plenty of seeds are yielded for increase, division of the roots should be avoided, the plant resenting interference. Indeed, one of the joys of this splendid subject is that it so appreciates being left alone that the longer it remains undisturbed the better it is.

Mr. Ingwersen tells me that the Homestall variety of P. g. var. Mariesii is an even better plant, but as the specimens he was good enough to send me have not yet become fully established, opinions of mine from actual comparison would not be justified. In any event the Homestall form must be a very good thing if it ventures even to equal the typical Japanese at its best. The latter is in every way such an excellent garden plant that it would be doing it an injustice to recommend it on the strength of the fact that it blooms at the "back-end" when there is little to compete with it, for it is able to hold its own and more with the choicest herbaceous subjects of the season. *A. T. J.*

ADENOPHORA FARRERI.

A day or two ago I saw, in a Dumfriesshire nursery, a good plant of this new Adenophora in full bloom, and it struck me as being one of the prettiest of this genus for the border of good hardy flowers. It is of erect habit and about two feet high, and bears a number of beautiful bright blue, bell-shaped flowers. These flowers are more tubular in form than those of most of the other Adenophoras. This species is hardy and is one of the numerous Adenophoras which practically take the place of the Campanulas in the higher parts of Tibet. It does not appear by name in Farrer's great work, *The English Rock Garden*, and I cannot tell from the references in the appendix of that work, whether A. Farreri is one of those given under number and without adequate descriptions.

PYRETHRUM HAROLD ROBINSON.

We have so long been accustomed to regard James Kelway as the finest of the single crimson Pyrethrums that it comes as a surprise to meet with that called Harold Robinson, a recently introduced variety with considerably larger flowers of as fine a colour. This grand Pyrethrum is of splendid habit and has long, strong stems, so that it is very valuable for cutting. When better known it will become a favourite, and will be much appreciated—as much, indeed, as that grand Pyrethrum, James Kelway, has been in the past. *S. Arnott.*

ROSE GARDEN.

ROSA OMEIENSIS AND R. SERICEA.

Considerable confusion of names exists in gardens between the Chinese Rose, Rosa omeiensis and the Himalayan Rose, R. sericea, of Lindley. The confusion would appear to have first begun when the enormous translucent form called var. pteracantha was first introduced to commerce by the late M. Maurice de Vilmorin. This was raised from seeds sent from Yunnan in 1890 by the Abbé Delavay, and named by Franchet R. sericea var. pteracantha. This was ten years previous to the introduction of the Mount Omi Rose, R. omeiensis, from western Hupeh, in 1900.

In *Plantae Wilsonianae*, Messrs. Rehder and Wilson place all the Roses formerly considered Chinese forms of R. sericea by Franchet and Focke under R. omeiensis. The true R. sericea, of Lindley, they consider as confined to India. The two characters cited as most readily distinguishing the two species are the greater number of leaflets in R. omeiensis, and its short, swollen, or fleshy, fruit stalk. The true R. sericea, Lindley, has a long, slender fruit stalk. The differences in the fruits are clearly shown in the two accompanying illustrations, R. sericea, Lindley, Fig. 87 and R. omeiensis, Rolfe, Fig. 88.

Mr. Wilson describes R. omeiensis as abundant in upland thickets, on the margins of woods and in forest glades on the higher mountain ranges of western Hupeh and Szechuan.

R. omeiensis, as cultivated in gardens, is a very variable species. The shoots may be smooth, or densely setose; there may be few, or very numerous, small, or large, spines; the number of leaflets varies from seven or nine to fifteen or seventeen, in the latter case I believe exceeding in number the leaflets of any other Rose. The colour of the fruits is also very variable. The type plant had red fruits with a yellow, fleshy stalk; var. atrosanguinea, Rolfe, has very dark crimson fruits, and in var. fructu-luteo they are golden-yellow; var. pteracantha, Rehd. and Wils., is the form with the enormous blood-red, translucent spines. The fruits of R. sericea are bright red, and have long, slender stalks.

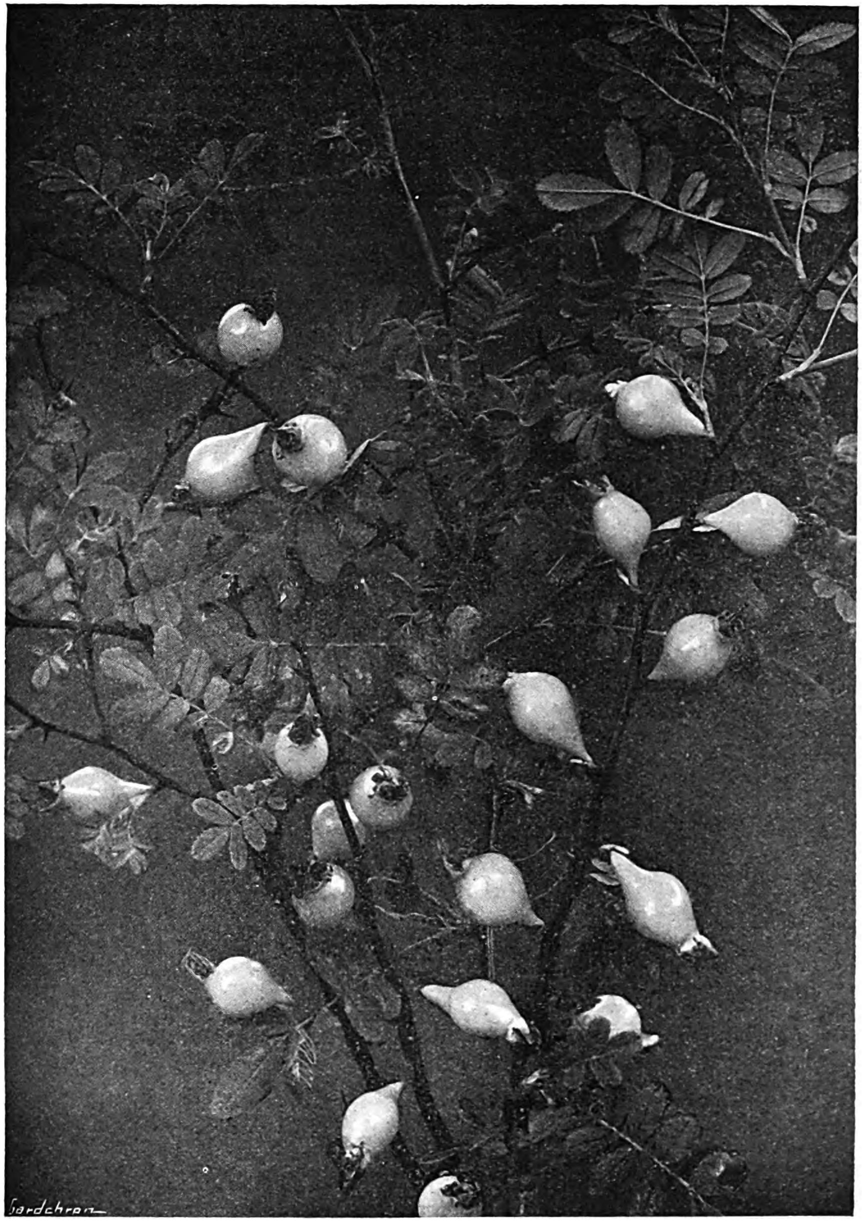

FIG. 88.—ROSA OMEIENSIS: FRUITING SPRAYS.

Among the wild Roses, R. omeiensis and R. sericea are easy to discern because of their long, slender, widely-arching branches freely clothed with the Fern-like foliage. Growing from eight to ten feet or more in height and diameter, the bushes are objects of grace and beauty from spring to autumn. They are among the earliest of the wild Roses to open their flowers—about mid-May. The white, or creamy-white flowers of these two species are distinct in having nearly always four petals arranged in the form of a Maltese cross. *A. Osborn.*

TREES AND SHRUBS.

DRIMYS WINTERI.

Known in its native habitat as El Canelo, this tree is regarded with respect almost amounting to veneration by the Araucarian Indians of the south of Chili. Under its branches were held their councils of peace or war against neighbouring tribes or families in less peaceful times, while its branches are still used as symbols of peace and justice. The Indians believe that anyone who utters a lie beneath its shade will certainly be punished within a very short time. Young Araucarian couples also make their vows under the Canelo, and these are considered to have the same importance as a religious ceremony, binding the parties concerned for the rest of their lives.

The wood of Drimys Winteri is highly aromatic, of little use for fuel even when dry, while if burned green it gives off a dense, acrid smoke very painful to the eyes. It was formerly much used as medicine, the leaves and bark being employed as poultices or in baths for skin affections and to cure scurvy.

It is one of the most beautiful Chilean trees, especially when seen *en masse*; commencing to flower in August, it is at its best during September and October, when the trees are smothered with creamy-white flowers borne in compound umbels. The black, oval fruits are also conspicuous in autumn and are beloved of the birds; they are fleshy berries containing many slightly curved, black seeds.

D. Winteri is, I believe, the only Chilean representative of the Natural Order Magnoliaceae. Growing in marshy woods and river beds, it never seems really happy unless it has its roots in water. It is a rapid grower, reaching, in the south and parts of central Chili (only in certain valleys), as much as forty-five feet in height, but it is comparatively short-lived.

As may be expected of a tree having a poor root system, the plants are frequently blown over, and when this occurs they immediately send up a forest of new growths vertically from the horizontal trunk. Occasionally specimens are found in the valleys of central Chili which are almost dry during the summer; under these conditions they form compact, well furnished trees or shrubs. *G. W. Robinson.*

OLEARIA OLEIFOLIA.

UNDER this name, a remarkably attractive Olearia has proved itself a valuable addition to hardy Olearias at Scarborough. Quite unlike the familiar Olearia Haastii, it has a spreading growth and bright green foliage. The leaves are of considerable width and bright green in colour, so one is at a loss to know how it has gained its name. Its flowers are slightly less pure white than those of O. Haastii and much less abundant, so they contrast very prettily with the green leaves.

Mr. Clark, the Corporation head gardener, is so impressed with its superior merit that he is inserting a quantity of cuttings. The healthy and spreading habit and cheerful colouring of the plant make it thoroughly attractive. If it has proved itself as thoroughly hardy inland as it has by the seaside, it is worthy of a place in every garden. *Edward H. Woodall.*

BUDDLEIA VARIABILIS VAR. NANHOENSIS.

FEW shrubs are more widely grown than Buddleia variabilis and its varieties, with the exception of this one, of later introduction and only just beginning to appear in some catalogues. It was found by the late Reginald Farrer in Kansu, south-west China, in 1914, and its varietal name refers to the Nan-Ho valley, where it was discovered. As in the type, the colour of the flowers varies from light mauve to deep purplish-mauve.

It is the only Buddleia, so far as I am aware, which can be grown in small beds and borders, for it seldom attains a height of more than four feet, even when in flower. It needs pruning in February, the young growths of the previous year being cut back nearly to the point of origin or to the first good pair of shoots. It appears to be rather less hardy than its near relatives, at least, while young, and in that stage should be protected during severe weather. *A. Petts.*

HERBACEOUS PAEONIES.

IN spite of the enormous array of excellent varieties in commerce, Paeonies have not yet become so common in gardens as other well-known border aristocrats. There are, of course, definite reasons for this, although the time is coming when these reasons will no longer exist. Primarily, the delayed production of flowers in newly-planted specimens has warned off those who like to see immediate returns for their outlay; but, owing to a better understanding of the life-history of the Paeony, this tardy production of flowers should soon be overcome.

Unlike the majority of herbaceous perennials, as most readers of *The Gardeners' Chronicle* are aware, the herbaceous Paeony has completed its work above ground by the end of August and the plant then commences to develop its first set of new roots, and it is on this autumn-produced system that a growth of fibrous roots is formed the following spring. It is on this secondary system of roots that the well-being of the plant depends, and it is therefore obvious that the ideal time to transplant Paeonies is during the month of September. All who have had any experience with these plants will readily admit that plants which are put into the ground during that month will flower much earlier than those which are planted at a later season. Nurserymen usually tell their prospective customers that Paeonies may be planted from September to March, and although this is perfectly true, yet it would get the Paeony into better repute if they made a strong point of advocating September planting.

When Paeonies are once established in favourable conditions they give as little trouble as any other border perennial, and they increase to quite large clumps without showing any signs of deterioration. It is worth while studying what these conditions really are. Haphazard cultivation probably accounts for failure to produce good flowering specimens. It is true Paeonies will thrive in most garden soils, but whatever the soil, it is imperative that it be properly prepared by good drainage, deep digging, and liberal manuring. Later on, the ground may be kept in good heart by occasional dressings of bone-meal and by summer mulches of rotten manure. While thriving in positions in full sunshine, I think most gardeners will agree that partially shaded situations are to be preferred, as the stronger colours will not fade so quickly and the flowers themselves will have a longer life.

Perhaps another factor which deters the multitude from growing Paeonies is their relatively high price. New varieties are certainly expensive. They cannot be otherwise when we consider that it takes something like fifteen years to produce enough plants of a new variety for commerce. It takes some years for a seedling to develop into a flowering plant, and many more seasons to propagate a sufficient number for sale. Fortunately, during the forty years that specialists have taken the Paeony in hand there have been evolved a large number of exceptionally fine sorts, and the stock of these is now large enough to enable the raisers to offer them at prices varying from two shillings to five shillings each, and no lover of Paeonies need complain at having to pay these prices for such worthy sorts as Baroness Schröder, a double, flesh-white variety, or the beautiful single-flowered Lady Helen Vincent, which has large, white flowers daintily tinted flesh. Only those who have had the privilege of seeing the valley of Paeonies at Langport in full bloom can form any idea of the wonderful range of shades and tints which are found in these flowers, to say nothing of their most alluring fragrance. When one considers the perfection that has been attained it is a matter for surprise that its numerous admirers have not yet founded a Paeony society to encourage its wider cultivation. The American Peony Society is doing very useful work and when we remember that some of the finest sorts grown in the United States originated in our own land, the formation of an English society might well be seriously considered.

Among the sorts that may be purchased at a moderate price, the following are of outstanding merit. Double-flowering varieties: Boule de Neige, sulphur-white, tipped carmine; Coronation, cream, edged light pink, golden anthers; Lady Alexandra Duff, French-white, fragrant, one of the most popular varieties in the States, and some experts say it is the best sort yet raised; General McMahon, deep purple-crimson; James Kelway, white, very fragrant; Le Cygne, milk-white, early. Single-flowered varieties: Flag of War, crimson; Lady Helen Vincent, white, tinged flesh; Lady Ley, soft rosy-pink, golden centre; Letitia, bright rose; Whitleyi, white, early; Wilbur Wright, deep maroon. The following higher-priced varieties are true aristocrats of the Paeony family; some are of recent introduction, and others are scarce, older older sorts. English Elegance, delicate flesh-pink, single flowers produced in bunches; Kelway's Lovely Lady, large single flowers, flesh-pink, turning white; Nellie, immense blush-pink, single; Wild Rose, white, speckled pink; Kelway's Gorgeous, full double, shining white, stated by the American Peony Society to be the second best Paeony in existence; Joy of Life, double, lavender-pink, very fragrant; Globe of Light, silvery-rose guard petals, pale rose and yellow petaloides; Marion Cran, semi-double, flesh-pink, turning to white. *H. Greaves, F.L.S.*

THE GENUS PRIMULA.

(*Continued from p.* 169.)

PULVINATA (Balf. f.). Cushion P.
(Bullatae).

A DELIGHTFUL dwarf, sub-shrubby, cushion-like, more or less evergreen species with a much-branched, woody rootstock, clothed with the dry, rust-coloured remains of old foliage. The leaves have lance-shaped, blunt blades about one-and-a-half inch long, tapering to pale green or white, glandular, concave, scarcely sheathed stalks, about equalling the blade in length; margins cut into numerous undulate, rounded, tooth-like lobes; both surfaces moderately clothed with capitate, translucent glands emitting a viscid secretion; upper surface intense green, somewhat deeply veined, underside paler. Flower stem about five-eighths-of-an-inch tall, reddish, viscid, bearing an umbel of two to three yellow blossoms, creamy-white on the reverse, on reddish, fragile stalks. Corolla about three-quarters-of-an-inch across, with broadly-heart-shaped, notched lobes, recurved at the tip; tube cylindrical, slightly longer than the calyx, with a ten-lobed ring in the mouth; the whole of the blossom is densely covered with minute, glandular hairs. Flowers in June.

Grows on precipitous, limestone cliffs, west of Atuntsu, in north-western Yunnan, at about 11,000 feet above sea-level.

Culture: As for P. Forrestii.

PUMILA (Pax). Pigmy Arctic P.
(Nivales).

A beautiful, dwarf, perennial species with a rosette of non-mealy, grass-like, pointed leaves one inch to three inches long; margins entire or furnished with remote, blunt teeth toward the tip. Flower stem one-and-a-half inch to two-and-a-half inches tall, slender, erect, non-mealy, bearing an umbel of one to three purple blossoms. Corolla about three-quarters-of-an-inch across, divided into five oval, retuse, slightly notched or entire lobes; tube cylindrical, nearly as long as the calyx.

Grows in damp situations among short herbage near the sea-shore, in St. Lawrence, north-eastern Siberia.

Culture: As for P. nivalis.

PUMILIO (Maxim.). Pigmy P.
(Farinosae).

A dainty, minute, densely tufted, non-mealy perennial species with elliptic or diamond-shaped, somewhat blunt leaves about half-an-inch long, tapering to a winged stalk about equalling the blade in length; margins entire or obscurely toothed. Flower stem short, bearing an umbel of one to seven pale rose-coloured blossoms. Corolla about three-eighths-of-an-inch across, with broadly heart-shaped, notched lobes; tube cylindrical, hardly longer than the calyx.

Grows in moist, alpine pastures, in the alpine regions of western Kansu, north-western China.

Culture: As for P. farinosa.

PURDOMII (Craib). Purdom's P.
(Nivales).

A beautiful, tufted perennial species with few, narrowly lance-shaped, pointed leaves from three to five inches long and half- to three-quarters-of-an-inch wide, tapering to a winged stalk; margins incurved, entire; upper surface coated with white meal, underside very densely so. Flower stem fairly stout, four to seven inches tall, erect, densely covered with white meal and bearing an umbel of three to twelve horizontal or drooping, lilac-mauve or bright violet blossoms with a greenish-yellow eye. Corolla about one inch across, with oblong or narrowly-oval segments; tube cylindrical, about five-eighths-of-an-inch long, almost closed at the mouth. Introduced in 1913. *Gard. Chron.*, 1913, Vol. LIII, Fig. 91.

Grows in damp, mountain pastures near Taochau, in western Kansu, north-western China, at 10,000 to 11,000 feet above sea-level.

Culture: Good, somewhat heavy, calcareous loam in a moist, open situation, well drained in winter, are the conditions indicated. *A. W. Darnell.*

(*To be continued.*)

AN ENGLISH GARDENER IN CHILI.

Chili is divided by its climate into three distinct zones, the northern provinces being dry and mostly semi-desert, and the south wet and well-wooded; however, for the purpose of these notes I propose to deal chiefly with the central provinces (roughly between parallels 31 and 35, S. latitude), where it rains during the winter months only (May-August). The remaining months form one long, continued dry period, which is accompanied by powerful sunshine and frequent winds, the combination of these conditions giving an exceptionally clear, dry atmosphere. From these facts it may easily be understood that the native plants belong to one of two broad groups: (a) Those which spring up with the first rain, grow rapidly, flower, fruit and die, or die back in the case of perennials; and (b) 1, trees and shrubs with thick, coriaceous leaves, extremely resistant to drought; 2, succulent plants and shrubs which drop their leaves and remain dormant; and 3, Cacti and Bromeliads.

Although very variable, both as regards dates and amount of rainfall generally, the first fall is in May. Immediately vegetation springs to life, and the brown, barren, semi-desert becomes clothed with infinite shades of green. Seedlings of all kinds of plants, shrubs and trees fight for supremacy and a place in the sun. One cannot fail to notice among the first and most vigorous many old acquaintances, which are more or less cosmopolitan; Thistles, in particular, have become firmly established, old clumps starting into growth and seedlings springing up everywhere in many areas, to the exclusion of everything else. Incidentally, they are turned to good account, the mid-ribs of the leaves being greatly appreciated as a vegetable, under the name of "Pencas," and the flower stems, known as "Tallos," are cut while young and eaten as salad. Rumex, both annual and perennial species, are common, as are Plantago lanceolata, Convolvulus arvensis, and a great many other "weeds of cultivation" with which we are only too familiar.

However, to come to the indigenous flora; as in most countries, the different authorities vary considerably in estimating the number of genera and species, but for the whole of Chili it is round about 5,000 species, many of which are endemic. The vast majority of these are only of botanical interest, and not worthy of consideration for purely horticultural purposes. From the point of view of plant ecology, there are three perfectly distinct types of vegetation in the central provinces:—1, The coastal flora, which might be conveniently sub-divided into (a) the sand-dunes, and (b) maritime flora of the rocky headlands and cliffs; 2, the dry plateaux and hills inland; and 3, valley bottoms and river beds.

The sand hills which extend along parts of the coast possess a strictly limited, but characteristic flora; a certain number of shrubs and stunted trees manage to exist in the hollows, but the majority of plants are low-growing perennials and bulbous plants, reinforced in spring by millions of annuals which have, indeed, a short life but a gay one! The shrubby perennials, which rarely attain more than a foot or two in height, are represented by Margyricarpus setosus, Colletia (hystrix ?), Ephedra americana (andina), and Acaena trifida. Another common plant is a small evergreen belonging to Asclepiadaceae. It has greenish-white, wax-like flowers, borne in closely-packed umbels, the habit of the plant closely resembling a low-growing Ivy. The leaves are triangular or linear, with auricled leaf-bases and in opposite pairs, but the short peduncles always twist to bring them to the light on the one side. All these subjects, and especially the Ephedra, have enormous root systems in proportion to the size of the plants.

It is largely among these clumps that the annuals find security and shelter during the seedling stage. One of the most drought-resisting shrubs which is found here belongs to Leguminosae; it has lemon-yellow flowers which are more tubular than is usual in this family, only opening sufficiently for the stamens and stigma to project. The foliage is dark greyish-green and imparipinnate, usually having about fifteen pinnae. About three feet high, it is slow-growing and apparently produces few seeds, for I have never been able to find one; it seems to increase largely by underground stems.

The family best represented among the herbaceous perennials is Compositae; there are at least a dozen species, one of these, with large, bright yellow ray florets, is one of the earliest spring flowers to bloom; and another which has spherical inflorescences, near Bidens, without ray florets, flowers right through the summer and dies back to a few inches of stem in autumn. A shrubby Compositae, with small, leathery leaves and compact habit, covering itself in summer with white, downy inflorescences, is one of the commonest plants along the coast.

Solanum crispum, a plant well-known in gardens at home, grows here like a weed, and makes big clumps; in summer, the leaves die off and the succulent stems remain dormant, again breaking into leaf and growth with the first rain. A compact-growing Linum, L. Chamisonis(?) is a showy plant; it has an enormous woody root-stock and an erect habit, typical of its family. The flowers are in terminal corymbs and bright gold in colour.

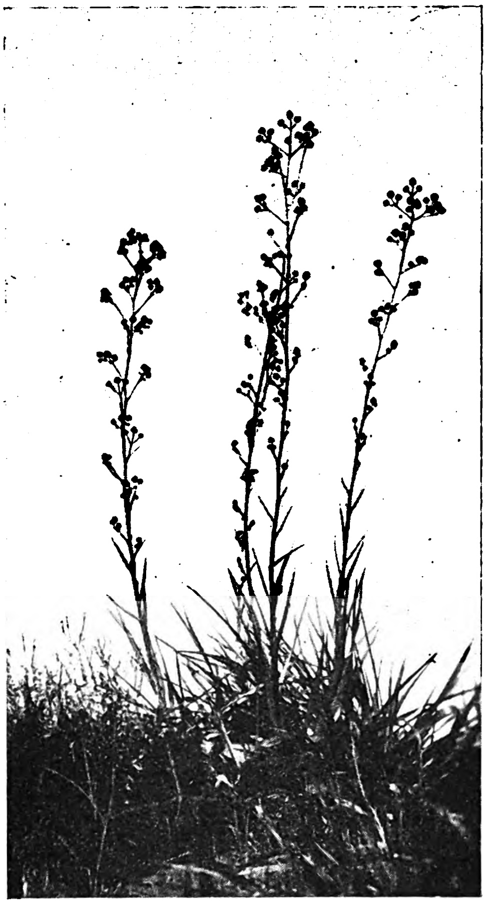

FIG. 89.—ERYNGIUM PANICULATUM.

Two species of Cactaceae are found here, one Echinocactus Ceratistes, "El Sandillon," rarely attains three feet in height by six or eight inches in diameter, and has numerous, small, rosy-carmine flowers, followed by red fruits, arranged around the growing point. The other, Cereus chilensis, known as "El Quisco," reaches so much as ten or twelve feet tall by about four inches in diameter and branches freely, forming numerous parallel stems. This species has white flowers, produced from the sides of the stems, and round, green fruits rather larger than a golf ball.

It is interesting to note that two widely different genera, botanically, Cereus and Euphorbia, remarkable for their similarity of habit, or as it is called, "Parallelism of Development," are here found together. However, there is no similarity between the individual species. The Euphorbia grows almost prostrate, with freely branching, fleshy stems, the growing shoots bearing linear or slightly obovate leaves about an inch long, and fleshy, black bracts.

Four species of Loasa are common here, all interesting as regards structure; three are annual and trail among the shrubs, often covering them; while the fourth is perennial and sends up an erect, stiff inflorescence with curious green, although rather insignificant flowers and equally curiously twisted seed vessels. The most vigorous grower, L. tricolor, is a rank weed, and possesses violent stinging hairs in profusion; the flowers form a beautiful colour contrast in scarlet and orange, and a similar but smaller species, equally as objectionable, has white flowers with gold and orange centres. Loasa artemisiaefolia (?) climbs by twining stems and covers large areas; it has fairly large orange flowers, each petal having the hollow, pouch-like form peculiar to this family.

A plant which, seen without its inflorescences, would deceive an experienced botanist, is Eryngium paniculatum (Fig. 89). The hard, parallel-veined, linear leaves, a foot or more long, are packed in dense rosettes, well-armed with spines and closely resembling a Dyckia or other small Bromeliad; indeed, it is only when the flowers are examined that one finds one is dealing with a Dicotyledon. Two species of Verbena also grow here in quantity, a mauve and a cream species, but although interesting, they are far inferior to the Verbenas of cultivation.

Here also grows Schizanthus pinnatus by the acre; in fact, on some of the slopes it is close enough to be mown with a scythe, and completely changes the colour of the landscape when in flower. Another plant, equally as prolific, is Lupinus microcarpus, which grows barely a foot high and is violet in colour. An interesting annual sometimes found in gardens is Schizopetalon Walkeri, a native of these sand-dunes. Typical of its family, Cruciferae, it is, as its name implies, conspicuous by its curiously cut petals.

I have only noticed one species of Calceolaria on these sand hills, and this prefers pockets or steep slopes, where it forms large rosettes of leaves, flat against the surface, in a similar manner to Ramondia, throwing up in spring or early summer strong inflorescences a foot or so high of a good deep yellow colour. Another common annual is a white Triptilion, which lasts indefinitely when cut. It is very near the blue T. spinosum, but not nearly so good, and differs in that the latter is perennial.

Monocotyledons, especially those with bulbous or tuberous roots, form a large proportion of the flora of these areas. From a purely decorative standpoint, the best flower is Leucocoryne ixioides, "El Huilli," a bulbous Liliaceous plant common on the sand hills, although not confined to them. The flowers are picked in quantity, and command a ready sale in the towns. The mauve flowers are borne in simple umbels, some three or four inches across, on thin, wiry stems, a foot or more high, while the bulbs are frequently as much below the surface.

Another bulbous plant which is very common is a greenish-yellow Amaryllidaceae, probably Hippeastrum species. There are many other species of these two families, not bulbous, and among them is an Alströmeria which does not grow more than eight to twelve inches high and has bright rose and yellow flowers; and a small, but curious Liliaceae with oval, fleshy roots. This plant, Trichopetalum stellatum, grows about one foot high, producing greenish-white flowers in which the three inner perianth segments are covered with white, hair-like excrescences; these give the flower a curious, furry appearance.

Common on the sand hills also is Herreria stellata (?), a small, trailing plant, generally prostrate, but sometimes climbing by twining stems. It has tubers generally about one inch long by half-an-inch top to bottom, from which are produced the thin, twisted stems, bearing lanceolate leaves about one-and-a-half inch long. It is dioecious, the flowers, on both male and female plants, being green and inconspicuous, but the triangular, membranous fruits which follow the female flowers are large and brown. *G. W. Robinson.*

EDITORIAL NOTICES.

ADVERTISEMENTS should be sent to the PUBLISHER, 5, Tavistock Street, Covent Garden, London. W.C.2.

Editors and Publisher.—*Our Correspondents would obviate delay in obtaining answers to their communications, and save us much time and trouble, if they would kindly observe the notice printed weekly to the effect that all letters relating to financial matters and to advertisements should be addressed to the* PUBLISHER; *and that all communications intended for publication or referring to the literary department, and all plants to be named should be directed to the* EDITORS. *The two departments, Publishing and Editorial, are distinct, and much unnecessary delay and confusion arise when letters are misdirected.*

Special Notice to Correspondents.—*The Editors do not undertake to pay for any contributions or illustrations, or to return unused communications or illustrations, unless by special arrangement. The Editors do not hold themselves responsible for any opinions expressed by their correspondents.*

Letters for Publication *as well as specimens of plants for naming, should be addressed to the* **EDITORS, 5, Tavistock Street, Covent Garden, London, W.C.2.** *Communications should be* WRITTEN ON ONE SIDE ONLY OF THE PAPER, *sent as early in the week as possible, and duly signed by the writer. If desired, the signature will not be printed, but kept as a guarantee of good faith.*

Newspapers.—*Correspondents sending newspapers should be careful to mark the paragraphs they wish the Editors to see.*

Illustrations.—*The Editors will be glad to receive and to select photographs or drawings suitable for reproduction, of gardens, or of remarkable flowers, trees, etc., but they cannot be responsible for loss or injury.*

Urgent Communications.—*If sent by telegraph, these should be addressed Gardchron, Rand, London; or by telephone to Temple Bar, 7818.*

Local News.—*Correspondents will greatly oblige by sending to the Editors early intelligence of local events likely to be of interest to our readers.*

MR. F. KINGDON WARD'S TENTH EXPEDITION IN ASIA.*

XXIX.—UPS AND DOWNS.

TO our surprise, on reaching the village, we were greeted by Hubble, our truant interpreter, who had been shooed out of Denning by the Political Officer's orders, and having nowhere to go, had returned to us.

For the next few days the weather continued wet, but much warmer, the temperature never falling below 60°. Few people visited us, although we were still planted in the fields where women and children were hard at work pulling up weeds; in fact, every day, in every way, our unpopularity increased. Many of the men had left the village, some, it was said, for Tibet, others for the Lohit Valley. We could buy almost nothing, and our rations were running low. Something would have to be done soon, or we should be driven out of this inhospitable valley by sheer want.

After the middle of July the weather turned fine and exhaustingly hot for ten days, temperatures ranging from 62° at night to 92° by day; there were frequent thunderstorms in the mountains, but most of the rain fell during the night. The damp heat and teeming insect life made the preserving of specimens very difficult, and much time had to be devoted to saving the collections already made, before adding to them.

The deep ravines which scored the slopes all around us were filled with small trees and bushes, among which were flowering species of Saurauja; a big, scented, white Jasmine; Mussaenda, and a compact, brassy-yellow-flowered Hypericum. On the cliffs, and in the beds of larger streams, grew herbaceous plants, species of Hedychium, Chirita, Lysionotus, Torenia, Lysimachia and a Commelina with small but intensely blue flowers; besides Anemone vitifolia, Campanula colorata, and a pink-flowered Begonia, with fine foliage and in the autumn bunches of scarlet fruits. I had collected seeds of this Begonia in the Seinghku Valley at 7,000 feet, but later in the year I found it growing in the Delei Valley at over 8,000 feet. All the same, I doubt if it is hardy.

I also made two excursions up the ridge and into the temperate rain forest above, passing each time through the leech belt, by no means unscathed, although the leeches were not such a pest in the valley as I had expected to find them. Now that the Rhododendrons were over the rain forest was very gloomy, although cool and pleasant on a fine day. There were few flowers. Just as the alpine region, light and airy, is for a short season characterised by an unparalleled wealth of brilliantly coloured flowers, so the forest, morose and dark, is distinguished by an overwhelming display of foliage. In the one, everything is sacrificed to the best possible display of the reproductive organs; in the other it is the vegetative organs which reach their greatest expansion.

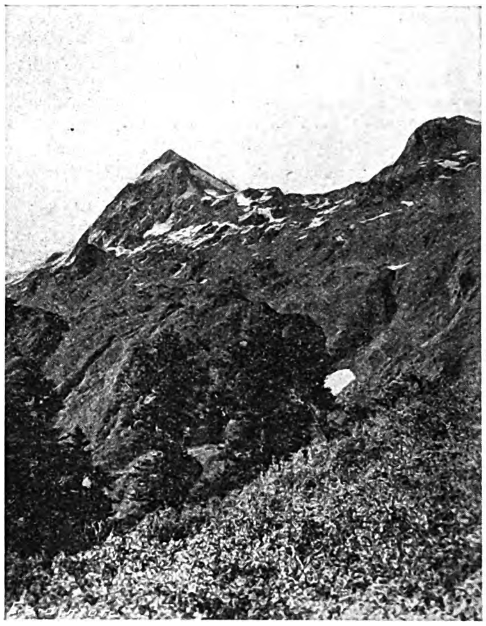

FIG. 90.—KASO: THE ELUSIVE PEAK.
15,100 feet high; the final ridge.

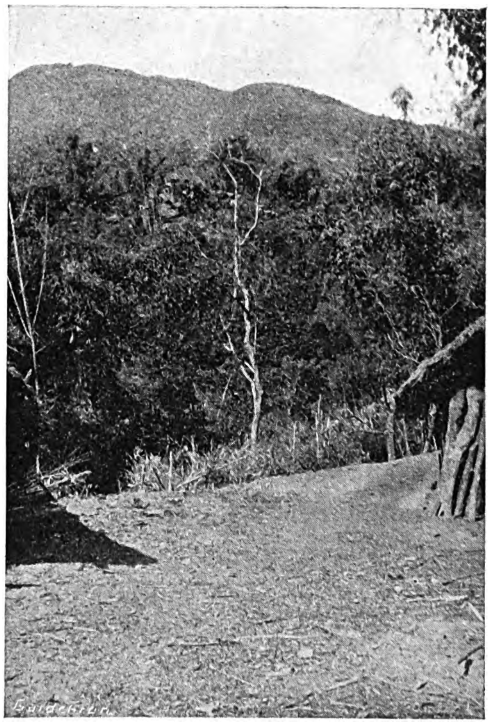

FIG. 91.—VILLAGE JUNGLE.

In the forest, plant competes with plant, and a measure of the slaughter is given by the number of dying and dead trees, and by the vast number of seedling trees which may be observed springing up everywhere to take their place—Rhododendrons, Acer, Magnolia, Abies, Tsuga, and many more. In the alpine region each plant competes rather against a grudging and, indeed, hostile Nature.

In the latter half of July, a bright yellow Begonia was flowering in the lower forest; a yellow-flowered Zingiberaceous plant, which grew on rocks; and a few ground Orchids. From the trees hung streamers of a leathery-leafed Aeschynanthus, its scarlet flowers striped with orange. I searched for the Butterfly Violet, but the plants were by this time so swamped by the undergrowth that they were very difficult to locate. Nor did the difficulty end there. Violets scatter their seeds by a spring-mechanism, with considerable force, and the first indication one gets that the seeds are absolutely ripe is usually an empty capsule; what one seeks is a capsule the carpels of which have just separated, but not yet been sprung. That, however, was not the worst of it, for I found that an enormous proportion of the ovules had been born with eggs in them—insect eggs, each of which had turned into a grub, consumed the embryo, and eaten its way out, leaving only the husk. But I was determined to get a few seeds of this fine Violet, and eventually I was successful. Furthermore, Colonel Enever Todd's interesting "Revision of Violas" published in *The Gardeners' Chronicle* (March 26, 1927, to July 7, 1928), had quickened my interest in the genus, which, hitherto, I had rather neglected, so that eventually I secured seeds of three other species, including two yellow-flowered alpines.

We had now to decide on some plan of action. The Mishmis refused to take us anywhere except down the valley, and the only alternative seemed to be to stay where we were. But our camp was badly situated, and if we returned to Camp III, a day's march southwards, there was at least a chance of reaching the Alps from there, since the Gam was friendly. I hoped to return to Tablekon in September, although I had a shrewd suspicion that every step down the valley would be permanent; my forebodings proved correct, for the Tablekon Mishmis, having at last rid themselves of us, threatened horrible reprisals on the Meiliang Mishmis if they dared to bring us back again!

But there was another consideration. We *must* send an S.O.S. to Sadiya for supplies, and as no Tablekon coolie would carry a letter to Denning, we had to find a man at Meiliang who would, those people being more accustomed to the journey. Besides, we were doing no good at Tablekon, and the prospect of sitting in that dismal camp for two months was not pleasing. Taking one thing with another, therefore, we decided to return to Meiliang and make another assault on the Delei-Dow divide from that direction. On July 21 we sent off half the loads, and next day we followed with the remainder; it was grilling hot, the path was completely hidden by the rank vegetation, and we arrived exhausted. However, we were now settled in a more comfortable camp, and a messenger was found to carry a letter to Denning.

Shortly after our arrival, the fine weather broke up and it rained sulkily for days on end; but during a series of short excursions I collected various Orchids, including the orange Dendrobium fimbriatum; a magnificent Hedychium with a 'bottle-brush' of vermilion and yellow flowers; Costus, Clerodendron, climbing Bauhinia, Sophora, Desmodium, Sambucus javanica, and more species of Saurauyja and Begonia. We made two long trips up the ridge we had climbed in April, to look for a suitable camping ground. This ridge, from a height of about 9,000 feet, runs due east to join the Delei-Dow divide, on which Kaso peak (Fig. 90) stands; but now there was another lower peak between us and Kaso. As usual, the trouble was—no water on the ridge—so we rigged up a tent-cover and a canvas bath to catch the rain.

Meanwhile, we were trying to persuade the Mishmis to carry a camp up for us. Sometimes the Gam was friendly, and promised to find coolies; sometimes he was indefinite and hostile. Sometimes the villagers visited us in embarrassing numbers; sometimes they gave us a very wide berth for days. One moon-lit night we

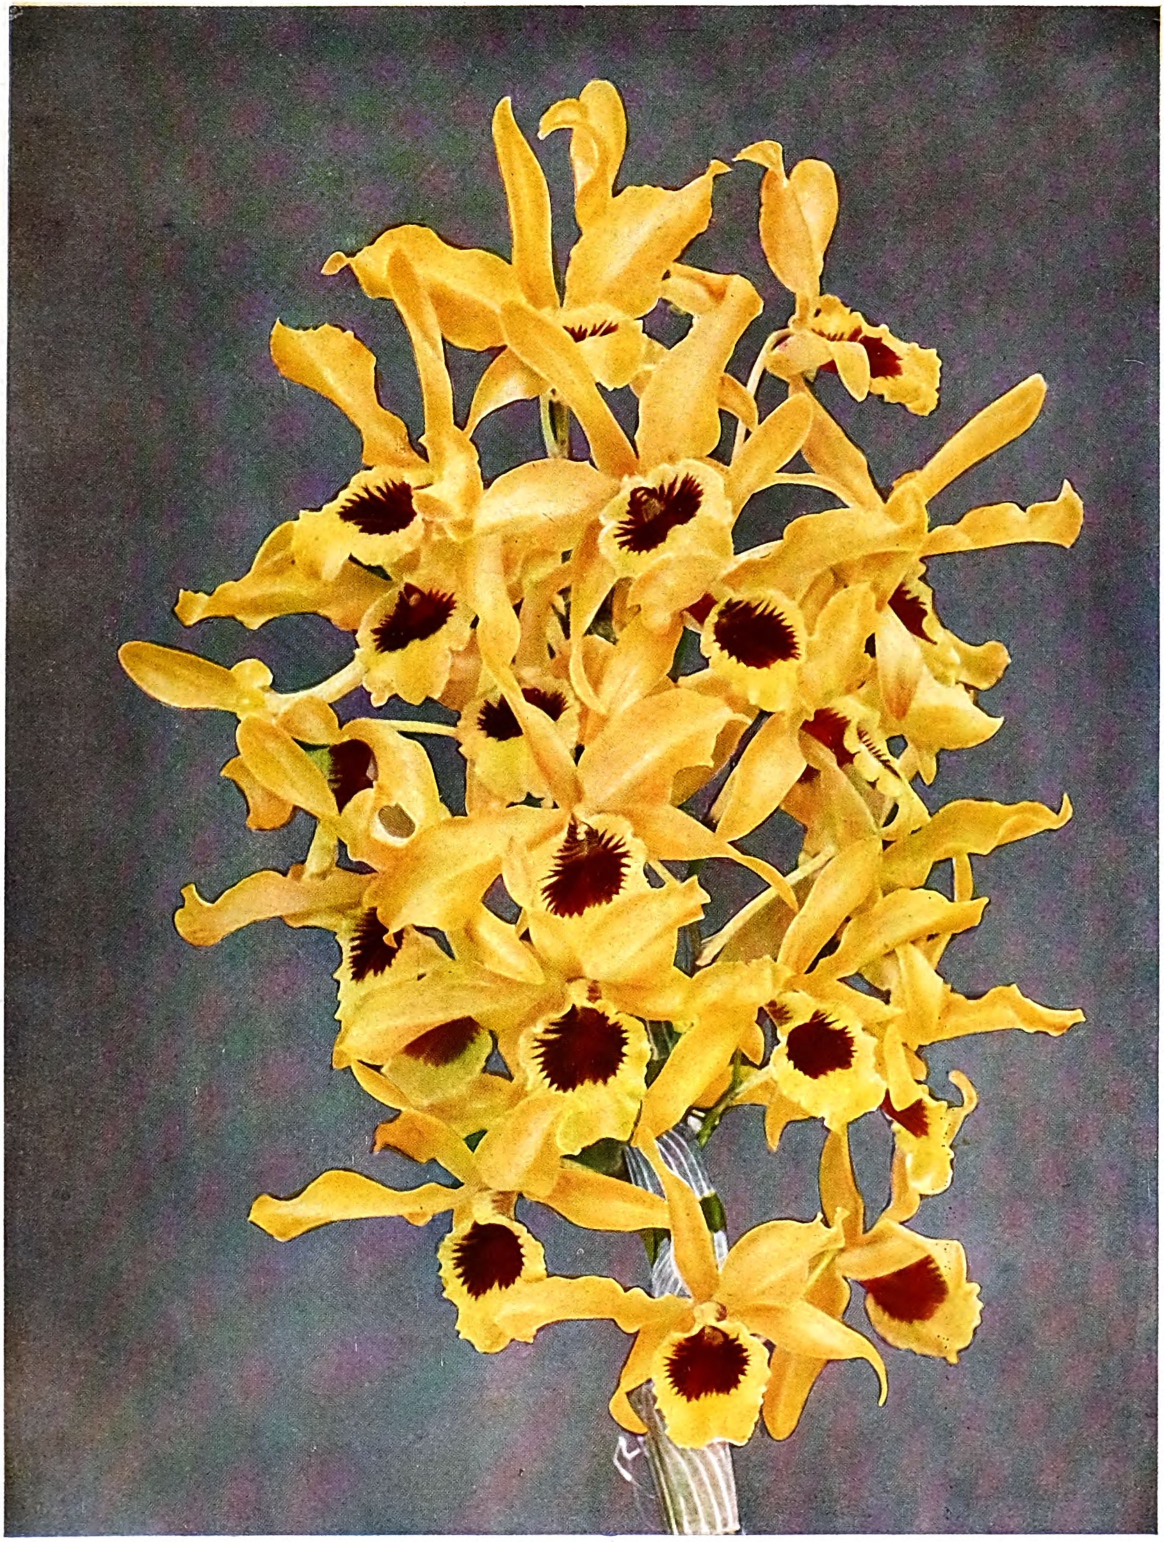
Kingdon Ward's Tenth Expedition in Asia were published in our issues of June 9 and 23, Vol. LXXXIII; July 7, 21; August 4, 25; September 1, 22; October 6; and November 3, Vol. LXXXIV; January 19; February 2, 16, 23; March 2, 16, 30; April 13, 27; May 18, 25; and June 1, 15 and 29, Vol. LXXXV; July 13, 27; August 10, 24, 1929.

Supplement to "The GARDENERS' CHRONICLE."



DENDROBIUM THWAITESIAE.

were visited by thieves who got away with a few things left lying about; we awoke to see the last of them making good his escape, but the discharge of a gun in the direction of the fugitives discouraged further larceny.

The Mishmis are, in fact, great thieves, and rob each other with as little compunction as they rob strangers. But they have no stomach for a brazen hold-up; petty larceny is their strong suit, and they would lurk round the cooking *basha*, trying to sneak cooking pots when the cook's back was turned, as a dog steals bones. We lost several pots and waterproof sheets from time to time, but such losses were not serious.

At last there came a crisis in our affairs; the Gam, who had not appeared for several days, sent word that the coolies would not take us up the mountain! Finis! We might as well pack up and return to Sadiya as sit here indefinitely. We had done our best, but we were dependent on the Mishmis for transport, and if they would not take us anywhere except down the valley, we were helpless.

Next day I sent for the Gam, to tell him that as he would not help us, we would return to Sadiya. He appeared to be in a good temper again, so I made a last desperate throw, as it seemed, having little hope left. "Why won't the Mishmis take us up the mountain?" I asked Hubble, "they said they would!" He affected surprise. "If you order the Gam to get coolies Sahib, he will do so!" I called the Gam. "Now," I said, "tell him once more I want twenty-five coolies to go up the mountain; its an order." This was translated, and the Gam promised the coolies! Then I asked for fifteen coolies to come next day and move the baggage which would not be required on the mountain, down to the village a mile away, where it was to be stored against our return; and they also were promised—and came next morning. At last things were moving again.

Still no news of our supplies; although the messenger had been gone nearly three weeks, and we were all on short rations. It seemed rash to go up the mountain with only a few days' food in hand, but now was the time to go, before the Mishmis had time to change their minds again. Also another fine spell of weather was upon us, so the start was fixed for August 17. It rained during the night of the 16th, which was just what we wanted to fill our reservoir, but the 17th was fine and hot, and the coolies were able to climb the steep path. We reached our camping ground late in the afternoon, only to find the reservoir empty, the water having leaked away or evaporated. Luckily, we had brought up a petrol tin full of water, sufficient for our immediate needs. *F. Kingdon Ward.*

PROBLEMS OF PLANT LIFE.[*]

VII.—Leaves and their Functions.

It is a matter of common observation that plants are either deciduous or evergreen. There is a border line, where we find certain evergreens tending to become deciduous, or deciduous plants taking on the evergreen habit. Such plants, like the animals which link up different genera and orders, have a special interest for the light they throw on the problems of life. While our problem at present relates chiefly to the deciduous types, and to the fall of the leaf, we shall find it of value to study the laws which regulate the life of the evergreen as well. Generally, it may be stated that, so far as trees and shrubs are concerned, the leaves of evergreens are much thicker, more coriaceous, smooth, succulent and poisonous than those of the other group of plants. It is easy to account for this.

For the most part leaves are to plants what the nutritive system is to animals. They act chiefly in two ways, taking in carbon dioxide from the air, and drawing up water from the soil. From the air carbon is obtained which serves as a plant food, while water is essential to the plant because it gives it turgidity, holds salts in solution, and responds to the action of the leaves under the influence of light. It is natural to ask why the majority of plants which are found in temperate regions are deciduous, and it is reasonable to assume that the answer is to a large extent to be expressed in terms of temperature. Given a sufficient and equable supply of heat and moisture all the year round, the evergreen condition becomes possible. Let the temperature fall low, and the ground, periodically, become very hard and dry, and the leaves may be expected to fall. That, roughly speaking, is what we find, but the law is not universal, and there are interesting anomalies which call for investigation.

Let us take the problem of the fall of the leaf. Why do leaves fall? The reasons are numerous. The most casual observation shows that leaves tend to fall whenever the supply of soil-moisture runs low, or when, in spite of an adequate supply, loss of heat is not made good, as occurs in the autumn when the sun is low. Now, simple as all this seems, a little investigation shows the complexity of the laws which govern growth. Suppose, for example, that the air is sufficiently warm to cause the leaves to transpire freely while the roots fail to act through cold or dryness of the soil, the water supply will soon fall short and the leaves dry up, droop or fall. Healthy plants will tend to respond to these conditions, with the result that they shed their leaves automatically in preparation for the season when such conditions occur. In autumn the soil cools, the plant fails to keep up the supply of moisture necessary for an evergreen condition, and a deciduous habit is produced. It reminds one of the hotel keepers who close down at the end of the season, to open again when there is a prospect of making a living.

But while the fall of the leaf is, in the main, due to the failure of the water supply through drought or cold, the whole of the phenomena are not thus explained. Some plants, for example, retain their leaves even when they have ceased to function, and everyone has noticed the Oak or Beech which has been trimmed, cut down or pollarded. The leaves will often remain until well into the next spring. It is the same with some evergreens if injured during the winter by severe frosts. And this leads to the observation, first, that native evergreens are few, and secondly, that such as occur in this country usually have small and specially protected leaves. Thus we learn that leaves are often shed as a protective measure. If our trees and shrubs normally produced large leaves which did not fall in autumn they would be subject to much trial from wind, frost, snow and other injurious meteorological conditions, and would have an enormously intensified struggle for existence. This is proved in severe seasons by the heavy toll that is taken in shrubberies among such plants as Laurels and Aucubas.

It would be of interest at this point to take up the problem of winter in relation to the functions of leaves, and enquire how the balance between the oxygen and carbon dioxide is maintained when the trees are leafless. But that is too large a subject to be treated here, and calls for separate consideration.

---

[*] Previous studies appeared in our issues of April 13 (p. 279), June 15 (p. 446), Vol. LXXXV; July 13 (p. 30), July 20 (p. 50), July 27 (p. 71) and August 17 (p. 130).

In deciduous trees the method adopted for shedding leaves has been often explained. It acts automatically in autumn, and is carried out with such care that no bleeding follows, and no open wound is left for the entrance of disease germs. Thus we come to a brief review of the economics of deciduosity. It is evident that the fall of the leaf is of prime importance in the economy of plant life. Let us take one or two of the more important points.

By the fall of the leaf the tree or plant is enabled to rest during that season of the year when it would be most difficult for it to obtain the necessary supplies. A word of caution, however, is here necessary, since certain hardy plants are able to grow during the late autumn and winter in spite of frosts, hardened soil, and a restricted water supply. Certain cereals, for example, are known to exude drops of water while standing in frozen soil or placed in snow with the temperature at zero. Interesting facts in this connection have been placed on record, and may be found in the memoirs and monographs of specialists.

The fall of the leaf saves the plant from many risks. If there is a heavy snowfall when the tree or shrub is covered with dense foliage, the weight often proves too great, and considerable injury results. High winds tear off the leaves, twigs and branches, and thus cause much damage. Frosts are extremely injurious to evergreens, while deciduous plants may escape unharmed. It is of further benefit to the tree that the leaves should fall, since light and air can thereby reach new shoots and young foliage. These can absorb the nutriment which is thus available and so growth is stimulated.

Add to all this the secondary effects of the fall. These are mainly two-fold. In the first place the fallen leaves protect the roots in severe weather, reduce the rate of evaporation and radiation, conserve the supplies of moisture and warmth, and so prevent the plant from suffering as it otherwise would. Here we are thinking of plantations, woodlands, forests and shrubberies, where the leaves are allowed to accumulate as they fall. Next, such masses of decaying vegetation form new humus, and by returning the unused salts which have accumulated in the leaves during previous seasons to the soil, keep up a supply of nutriment and prevent soil exhaustion.

It hardly needs to be stated that the foregoing notes are intended to be suggestive rather than exhaustive. So much special work has been done in the field and in laboratories at home and abroad during the present century that one who wishes to go more fully into the subject has only to consult one of the recent text-books and follow up the matter along the lines usually suggested in the appended Bibliography. *Hilderic Friend.*

NOTICES OF BOOKS.

Fruit Culture.*

In his introduction to this book the author states that it is intended to solve some of the problems which worry the beginner. A work having this object should be both modern and correct. Unfortunately, this one cannot claim to be either. Although it is a new edition, it contains a good deal of matter which is quite out of date. Still more unfortunately, the information is so often wrong that the book is robbed of any value which it might otherwise have had. A few of the mistakes, taken at random, will suffice to show that the volume is unworthy of serious attention.

One of the subjects on which the amateur should have modern guidance is that of the best stocks for trees intended for garden culture. All that is offered here is the remark: "The stock generally chosen for the Apple is the Paradise, a species of Crab, and for the Pear, the Quince." From this the beginner might imagine that there is only one type of Paradise, and that it is much the same as the Crab. The subject of pollenation is muddled and evidently not properly understood by the author. He seems to think that only self-fertile varieties are of value for pollenating others, and that self-sterile varieties are useless for this purpose. He is also under the impression that such subjects as Apples and Pears are capable of being wind-fertilised. "The wind may scatter the pollen widely," he writes. The directions for pruning are far too meagre to be of any real assistance to a beginner. The shoots of a newly-planted tree, we are told, "should be shortened sufficiently to cause some of the buds near the base to break in spring." The novice is left to guess how hard he must prune to bring about this result. A standard is described as a bush on a tall stem, requiring exactly the same pruning as a bush; and an illustration of a pruned standard shows the tree closely spurred and severely thinned, in a way which would certainly delay its bearing for a good many years. "The ordinary cordon," is described and illustrated as having two horizontal branches, one on each side of the stem, about two feet from the ground.

The chapters on pests and diseases are even more freely sprinkled with errors. Hairy caterpillars, we are told, form the greater part of the tissue-feeding class, a statement which seems to ignore the winter moth and various tortrix larvae, which are far more numerous and harmful. To combat these caterpillars the old Paris green is recommended, no mention being made of arsenate of lead, which superseded it years ago. For sap-sucking insects the unfortunate reader has the choice of a very strong soap solution (at the rate of 25 lbs. per 100 gallons!) or a paraffin emulsion which would undoubtedly do much harm to the foliage. Nicotine is not included! No mention is made of tar-distillate wash, the only winter wash described being an out-of-date caustic soda, crude potash, and soap mixture. Fruit-growers would be glad if it were possible, as stated, to eradicate Apple blossom weevil by the use of this wash in winter. The formula given for Bordeaux mixture includes 2 lbs. of copper sulphate in ten gallons of water, or more than double the strength of the normal 8-8-100 formula, which itself is stronger than most growers dare to employ. *M. G.*

Consider the Lilies.*

The publication of a second edition of Mr. W. E. Marshall's book, *Consider the Lilies*, which is a treatise on Lilies and a trade catalogue in one, is at once a tribute to the keen interest taken in these plants by American gardeners of recent years and to the author's enthusiastic advocacy of their cultivation as garden plants, an advocacy which has helped materially to arouse and maintain that interest.

Since the book was first published the Introduction has been revised and it now covers a good deal more ground than the first edition in regard to the preparation of the soil for Lilies, the time for planting bulbs of the different species, the situation in which each is likely to thrive, and so on. The author disregards the oft-repeated view that Lilies are none the better for stimulants, and like others before him, finds that although all the manurial value might be supposed to have vanished from it, there is no stimulant like old stable manure. He quotes an experiment made by a Lily grower, who, noticing that the leaves of some healthy plants of L. auratum were inclined to turn yellow when they should have remained green, dosed them with iron salts, with the happiest results.

Among such interesting matter, seldom found in a catalogue, there are practical hints on the propagation of Lilies from seeds, scales, bulblets and bulbils, and on the use of ground covering for the stem-rooting species; and, inevitably, these hints apply with more force to American gardens than to those in this country.

The author acknowledges his indebtedness to our columns, and quotes at length from them where the context is appropriate. The book is copiously illustrated in colour, and we can recollect no trade catalogue of plants in general, still less of Lilies in particular, which approaches it in the mass of illustrations. That they are not all of equal merit, goes without saying, and where the reproduction of plant photographs by three-colour process is concerned, there seems to be the same difficulty in the United States as there is here in ensuring that the printed colour shall even approximate to that of the natural tint.

GARDEN MANURES FOR SEPTEMBER.

With the advent of September the use of that large selection of relatively quick-acting fertilisers which are so helpful to cultivators during the active period of growth becomes definitely restricted, and attention is diverted more to the preparation of the soil for future crops than the direct supply of nutriment to those nearing maturity. And while it is of the utmost importance that the uses and effects of these quick-acting fertilisers should be closely studied, if maximum results are to accrue from their application, it is equally important that a wide outlook should be taken in the use of that even larger group of relatively slow-acting manures, most of which are best applied and many of which can only be applied during the more dormant season.

From the plant nutrition point of view, the division of these groups is rather one of convenience than reality, for the final result is to render available for the nourishment of the plant all those elements necessary to its maximum development; but, whereas the application of stimulating fertilisers during active growth is largely confined to minerals used as top-dressings, which are carried down to the feeding roots by water, the preparation of the soil during the dormant season embraces the use of that large group of bulky organic manures which is the basis of all good cultivation.

The relation between physical cultivation and manuring has been discussed frequently in these pages, but at the beginning of another season of soil preparation for future crops, it may not be out of place to emphasise once again that not only is thorough incorporation with the soil of added ingredients an essential factor if maximum results would be obtained, but also that full results cannot be obtained from the application of quick-acting fertilisers in next year's period of growth, unless previous physical preparation is thorough. It is obvious then that in the preparation of soils from now onwards much forethought and judgment is necessary, for this factor of thorough incorporation and physical preparation is only possible when the ground is crop-vacant, and in carrying out this work during the dormant season a network of tiny channels is being effectively laid to act as express delivery of those quickly soluble fertilisers which we can so profitably use during the active growing season.

At the present time much new development work will be contemplated in many gardens, which entails the preparation of sites and the use of various manurial ingredients. Probably the most pressing of these is the sowing of grass seeds for new lawns. The sites for these should have been prepared some time ago, to give the whole mass time to consolidate and in some cases seeds may be already sown, but early September is quite a good time to complete surface preparation, and on light, sandy soils where a deficiency of potash may be suspected, a dressing of sulphate or muriate of potash at the rate of about one hundredweight per acre, affords a ready means of making good any probable deficiency and may materially assist growth so soon as the seedling plants have established themselves.

Other works of preparation which call for attention at the present time are the making of new Rose gardens, the preparation of sites for planting fruit trees and the transplanting of trees and shrubs, particularly evergreens.

---

* *Fruit Culture*, by H. C. Davidson, Garden Editor of the *Daily News*. London: John Lane; pp. 142. Illustrated. Price 3s. 6d.

* *Consider the Lilies*, 2nd edition. W. E. Marshall and Co., Inc., New York, 1929. Price not stated.

In all these works the manure problem presents itself immediately, and in all cases the use of some type of bulky, organic manure is desirable. Farmyard manure naturally claims attention for these purposes, and although it is not quite free from the objection that some loss of nitrogen may occur before plant growth can absorb it, this disadvantage is at least compensated by the fact that under present soil conditions its thorough incorporation with the soil is easy, and in digging or trenching operations uniform distribution through the mass is assured, and the danger of losses through denitrification minimised.

Among other manures supplying the same plant foods, which are very slow in action and consequently suitable for use in present soil preparations, shoddy, feathers, horn and hoof refuse, and sewage sludge may be mentioned. These constitute excellent organic manures, the nitrogen content of which becomes liberated gradually, and the cellulose material decomposes slowly to form humus for future bacterial work. Such manures, and also ground bones, are extremely valuable for mixing with the soil when preparing for the planting of hedges, fruit trees, and other permanent trees, owing to their slow process of decomposition, with the result that food supplies are provided over a very long period, a great consideration where permanent plants are concerned.

Of the mineral manures which may be used with advantage at the present time, basic slag may be mentioned as the most important for the supply of phosphorous, and its use in conjunction with any of the above mentioned manures may be considered. Generally speaking, farmyard manure and similar bulky manures are not particularly rich in phosphates and addition by means of a mineral phosphate becomes necessary in some soils. Wherever its use is considered desirable, however, it should be applied to the surface after digging or trenching is completed, as owing to its extremely fine state of division and its heavy nature, it is soon carried down to a considerable depth. Originally introduced as a refuse from the Bessemer steel process, basic slag at one time contained so much as forty per cent. of phosphates, but the process has now been superseded by the open-hearth process, and present day slags seldom contain more than thirty per cent. of phosphates, and some of them as low as eighteen per cent., so that in giving a present day low-grade slag it would be necessary to apply approximately double the weight of the earlier high-grade slag to achieve the same results. Besides the provision of phosphates, slags also give a fairly high percentage of lime and this tends to maintain the lime content of the soil, but it should in no case be considered as an efficient substitute for lime. *W. Auton.*

FRUIT GARDEN.

ORDERING FRUIT TREES.

THE chief point to remember in connection with the cultivation of hardy fruits is to grow the right kinds and varieties, which have been worked on stocks most suitable for the purpose for which they are intended. One great drawback to fruit culture in the past has been the time that must necessarily elapse after planting before a return can be realised. According to the older methods, it was useless to expect anything like a profitable return from the fruit trees for at least eight or ten years after planting. Modern science and practice have, however, done much to alter this, for by the use of approved dwarfing stocks a great change has been accomplished in modern fruit culture.

A visit to a good fruit nursery at this season of the year is always interesting and instructive. There, young trees of both old and new varieties may be seen growing in quantities, and their merits compared, for such a visit will reveal not only the various forms in which the trees are grown, but the varieties and the root-stocks on which they are worked.

In purchasing fruit trees, the fruit-grower should deal only with nurserymen of good repute—those who realise and appreciate the importance of the relation of the tree and its fruits to the rootstock, and who can not only supply the varieties true to name, but also guarantee the stock on which the trees are grown.

Fortunately, the root-stock question is no longer the haphazard business it once was, thanks to the research work carried out at East Malling Research Station, Kent, and to the co-operation of our fruit tree nurserymen in selecting and propagating. There ought now to be less risk, if it is always borne in mind that two economic interests are concerned—the gardener's and the nurseryman's. The immediate interest of the fruit-tree nurseryman rests in securing stock that is cheap, that makes a good union when budded, and that makes a marketable tree quickly. But there is more than the immediate interest at stake, for the disposal of trees that do not give satisfaction to the planter is, in the long run, not conducive to a good business reputation, and so the nurseryman employs his knowledge of the proper use and selection of root-stocks, and his skill as a propagator to the mutual advantage of both parties.

"Quality will be remembered long after the price is forgotten," is the avowed maxim of a certain famous business house; so let the gardener meet the producer half way and be prepared to pay a fair price for a fair article, for it must be remembered that the responsibility does not rest with the nurseryman alone, for so long as we growers stand out for the so-called cheap tree, ignoring real value, the nurseryman is forced, against his better judgment, to take the line of least resistance and offer cheap trees, finding difficulty often in selling better quality stuff.

Before gardeners order new trees, it is important they should decide exactly what they want, and then give their orders in good time. It will be of the utmost assistance to the nurseryman, and it may prevent buyers from being disappointed at finding all the best stuff gone. The gardener must also decide the size, form, and age of the trees he is going to purchase. Some gardeners like to form their own trees from the start and, therefore, buy maidens. Others prefer to purchase three- and four-year- old stuff on which the initial framework has been started, with the idea of obtaining some return in less time than from younger trees. But the younger the tree, the less disturbance it suffers in transplanting, and the more readily it re-establishes itself. *H. H. C.*

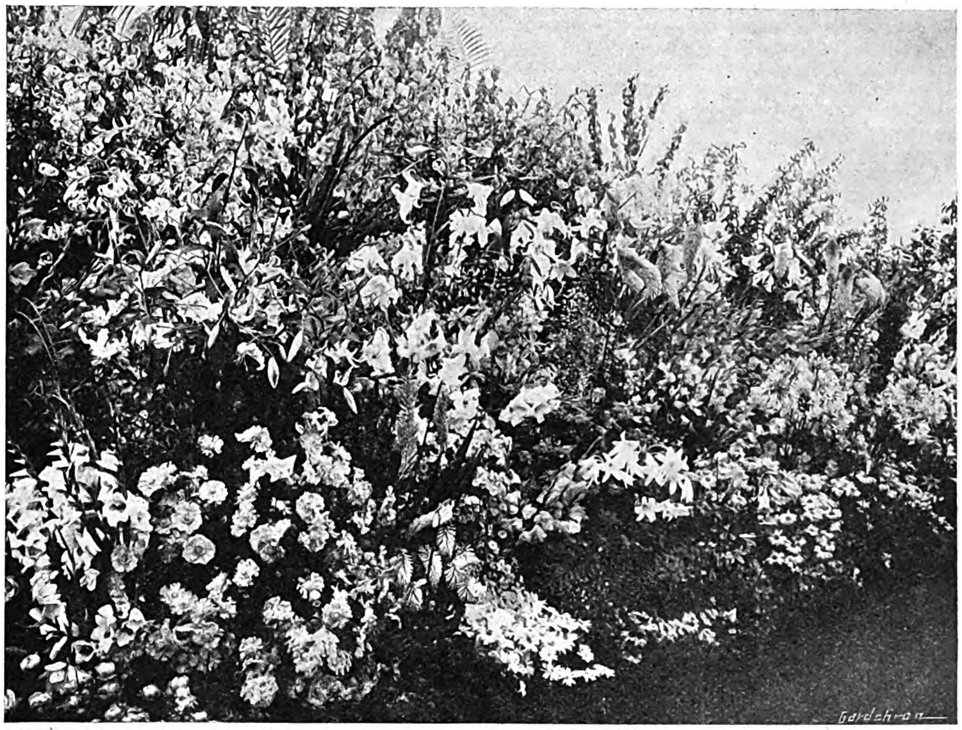

FIG. 94.—SOUTHPORT SHOW: MESSRS. BEES, LTD.'S EXHIBIT OF HERBACEOUS FLOWERS, etc. (see p. 191.)

REMARKS ON THE CONDITION OF THE FRUIT CROPS.

(See Tables and Summaries, Ante pp. 112-118.)

(Continued from p. 170.)

HERTFORDSHIRE.—The fruit crops, generally, are quite up to the average. Apples are very good, especially on orchard trees; such varieties as Lane's Prince Albert, Blenheim Pippin, King of the Pippins, Bramley's Seedling, Keswick Codling and Lord Derby are carrying very heavy crops. Pears are carrying smaller crops than usual, but the quality appears to be good. Owing to the severe frosts, Plums are much below the average although the trees flowered profusely; the Plum trees on walls, however, have a good crop of splendid fruits. Cherries are a full crop, and the fruits are of fine quality, both sweet and Morello varieties. All kinds of small fruits, especially Black Currants, have been plentiful and good. Strawberries, I am glad to state, have been the best crop for years. The soil here is of the tenacious London clay. *Edwin Beckett, Aldenham House Gardens, Elstree.*

—— Our Apple crop is very disappointing. Pears, Plums, Damsons, Cherries, and all small fruits are good, with the exception of Strawberries, as the hard winter killed most of the latter. The soil in these gardens is rather heavy, the subsoil being of gravel. *John Dewhurst, Gilston Park Gardens, Harlow.*

LEICESTERSHIRE.—After a very late start, most fruit trees opened with a good show of bloom, but the Plums were cut off by late frosts. Apples, in my opinion, suffered through the dry state of the soil for the time of the year, the result being only an average set, but the fruits are of a very clean and healthy appearance. Stirling Castle and James Grieve are carrying good crops. Peaches and Pears are also bearing splendid crops of good, clean fruits, and small fruits were exceptionally heavy. The Strawberry crop was light, but not so poor as might have been expected considering their appearance early in the spring, when it was almost impossible to find a green leaf. The soil here is more on the light than the heavy side, and of a good depth, on gravel. *M. L. Garrett, Misterton Hall Gardens, Lutterworth.*

—— At the time of writing, fruit crops here are well up to the average, except Strawberries, which have never recovered from the severe winter and prolonged drought since. All crops appear remarkably clean, but would benefit greatly by copious rain. The soil here is heavy. *David Thompson, Whatton Gardens, Loughborough.*

Northamptonshire.—Considering the season, fruit crops in these gardens are good, with the exception of Apples and Plums, the crops of which are very thin. Plums blossomed profusely, but severe frosts on April 21 and 22 destroyed the prospects of good crops. Peaches on a south wall are carrying excellent crops, and the trees are clean and healthy. Raspberries are a very heavy crop, but late in ripening. Strawberries had to be afforded copious waterings, but the results well repaid the labour, a good average crop of excellent fruits being obtained. Sir Joseph Paxton is our best maincrop variety. *F. W. Gallop, Lilford Gardens, Barnwell, Peterborough.*

Oxfordshire.—This fruit report is the average of about fifty centres in the county. With few exceptions the Apple crops are either average or under, but mostly under. The best croppers are Bramley's Seedling, on heavy soils; Lane's Prince Albert, Golden Spire and James Grieve on ironstone and light soils. Apples on heavy soils are about five per cent. above average, while on the light soils they are twenty-five per cent. under. Pears on heavy soils are average, but on light soil twenty-five per cent. under. Plums are under average on all soils. Cherries are average crops on limestone brash, but under average on all other soils, except Morellos on ironstone, which were an average crop. On the heavier soils the Apricots, Peaches and Nectarines have done better than on the light soils. With regard to small fruits, Gooseberries were under average on all soils, except clay. Currants were over average on most soils, the outstanding exception being Black Currants, which were twenty per cent. under average on ironstone soils. Strawberries on all soils except clayey or heavy loams, were under average. *Samuel Heaton*, 38, *Botley Road, Oxford.*

—The fruit crops in this district are much below average, particularly Apples and Plums, which are a failure in this garden. This is due to the cold winds and sharp night frosts during the setting of the bloom. Pears on walls are a fair crop and swelling well; the same applies to Peaches and Apricots outside. Gooseberries, Currants and Raspberries have cropped heavily. Strawberries set a fair crop, but the fruits were small owing to the prolonged drought. Caterpillars on Apples and Plums have done a lot of damage in spite of repeated spraying. The soil here is a thin and light loam, on limestone brash. *Ben. Campbell, Cornbury Park Gardens, Charlbury.*

—— The fruit crops, which looked promising at the flowering stage, owing to the late frosts are very disappointing. Among Plums and Peaches, some trees have average crops, but others are barren. Pears and Apples are an average crop, but the long spell of drought caused many of the fruits to fall. Black Currants were very poor; other small fruits were very good. Strawberries produced plenty of blossom, but late frosts completely spoilt them. The soil here is very light and sandy. *B. Elkington, Cotefield Gardens, Banbury.*

——The fruit crop, on the whole, is not all one might have hoped for, taking into consideration the amount of blossom the trees carried in the spring, but owing to the long period of cold, frosty nights a good deal of the unprotected blossom suffered, resulting in a lighter crop than was expected. The absence of insect pests this summer is very marked; I have not known so little in this district before. Small fruits have come out well, but all crops suffered through lack of rain. The soil is a heavy loam over blue clay. *Victor R. S. Gammon, Eynsham Hall Gardens, Witney.*

Staffordshire.—The fruit crops here compare very favourably with those of other years, except Apples. Some varieties are carrying a good crop, *i.e.*, Gladstone, Duchess of Oldenburgh, and Lane's Prince Albert. The early blooms on Plums and Pears on walls were killed by frost, but later blooms have resulted in a fair crop. Apples suffered most from insect pests; Plums and Pears are very clean. The soil here is a stiff clay, but is in a very friable condition owing to the severe winter. The garden slopes to south-south-west, and is well sheltered from south-west and east-north-east. Damsons, of which a lot are grown in this district, are a very thin crop, although the weather was favourable to setting. I have seen one good crop of Apples in this district, and that in a very exposed garden. *J. W. Miskin, Woodseat Gardens, Rocester.*

—— The fruit crops, on the whole, are very good, and they withstood the drought remarkably well. Among Apples bearing good crops are Bramley's Seedling, Irish Peach, Keswick Codlin, Lord Suffield, Red Astrachan, Cox's Orange Pippin and Annie Elizabeth. Pears have also done well in places, especially the varieties Marie Louise, Comte de Lamy, Doyenné du Comice and Hessle. Plums are very uncertain and in many places are a failure. Fruit trees generally are free from pests and are making good growth. Raspberries have done well. The soil here is gravelly, resting on a subsoil of gravel and rock. *Edwin Thomas Gilman, Hillside, Rugeley.*

Warwickshire.—There can be little doubt that the scarcity of the major fruit crops generally is due to the inclement spring, as not only was blossom ample but of good quality. Apples have suffered the worst, and in these gardens only one variety, King Edward, is carrying a full crop. Beauty of Bath, Irish Peach, Worcester Pearmain, James Grieve, Ribston Pippin and Rival are carrying moderate crops, but Bramley's Seedling, Bismarck, Lane's Prince Albert, Pott's Seedling, Lady Henniker, Peasgood's Nonsuch, Golden Spire and Cellini have few or none. The excellent position as regards Plums is undoubtedly due to wall protection, as bush trees standing only twelve feet away from the wall are carrying much smaller crops than those against the wall. Substantial thinning has been necessary on walls, however, with the following varieties:—Rivers' Early Prolific, Czar, Coe's Golden Drop, Jefferson, Kirke's, Monarch, Pond's Seedling, Green Gage and Victoria. Curiously enough, this position is reversed as regards Pears, bush trees at twelve feet from the wall carrying heavy crops while trees trained on the wall have few or none. The lightness of the Strawberry crop is not entirely due to frost, although a large number of the primary flowers were blackened in May, but largely to the fact that the rainfall during the four active months was abnormally low, the total being only 3·22 inches, distributed as follows: March, ·08; April, 1·04; May, 1·85; and June, 1·25 inch. The soil here is strong clay, overlying felspar rock, and is admirably suited to the cultivation of fruits. *W. Auton, Moreton Hall Gardens, Moreton Morrell.*

—— Owing to the prolonged drought in 1928, fruit trees in this district received a severe check, and in consequence flowered sparsely during the present year, except in specially favoured situations. Frost did some damage to Apples, Pears and Plums, but the "set" is, on the whole, proportionate to the amount of blossom the trees carried. Fruit trees generally are vigorous and healthy, and crops are entirely free from pests. Fruits, although not plentiful, are swelling satisfactorily, except in the case of Plums, which "ran off" badly on account of the drought and low temperature. Black Currants were the fruit crop of the year. Gooseberries have also been good. Strawberries were slightly damaged by frost, and the crops also suffered through drought. *Henry Dunkin*, 86, *Emscote Road, Warwick.*

—— The fruit crops in this district are rather disappointing. There was a good show of bloom on most trees, but a large percentage of the Apple and Plum blossom did not set, no doubt owing to the excessive drought of last season, followed by a dry spring this year. Fruit in exposed situations suffered very badly from sharp frosts at the end of May. Apples are a very light crop in this neighbourhood. *A. E. Moss, Billesley Manor Gardens, Alcester.*

(*To be continued*).

HOME CORRESPONDENCE.

A Charming Dwarf Annual.—In your issue of August 17, (p. 136) Mr. Emmett mentions three dwarf annuals as well worth growing. Might I call the attention of your readers to another quite as pretty and very little known so far as I am aware. I obtained a few seeds of it under the name of Felicia Bergeriana from a friend, who informed me he had got it sent from Spain. Nicholson describes two species of Felicia, both fairly tall and neither of them blue, so whether they are in any way connected, I have no means of ascertaining. The subject of this note is a charming little plant, not more than six inches in height, the foliage making neat mats on the ground and the flowers rising about four inches above. The flower suggests a small Agathaea coelestis, but of a far more beautiful blue. I sow it indoors and transplant the seedlings from boxes, but I am certain that on any reasonably light soil it might be treated as an ordinary annual. *J. Hill, Rosemount Gardens, Monkton.*

Fruit Trees for Ornamental Purposes.—From time to time, the question of planting fruit trees for ornament arises in the gardening press. It is surely not because their great beauty is unappreciated by the landscape gardener and others interested in the planting of public parks and private grounds. The glorious visions of the fruit trees in full bloom in the Cherry-growing district of Buckinghamshire, in the Wisbech district of Cambridgeshire, in the Vale of Evesham, and in certain districts of Kent—to mention but a few—are certainly such as to uplift the heart of man. There must be some underlying reason why such trees are not so used, and it may interest readers to seek the cause. The principal reason why, I think, they are not used in public parks is, that youthful human nature being what it is, it is not wise or expedient to put the temptation in its way to break off branches of flowers, or to damage the trees and surroundings in purloining the fruits. The mischievous propensities of youth are a great grief to public park keepers. Secondly, the trees possess no marked advantages over what may be termed the strictly ornamental sections of the genus Pyrus and Prunus. Pyrus (Malus) floribunda and its varieties give us quite a range of colour in flower and foliage from the pale pink form to the dark red variety atrosanguinea, which is not excelled in the fruiting section. Pyrus baccata in flower and fruit—the size of which offers no great temptation—furnishes a small tree or large bush. Pyrus spectabilis and P. Scheideckeri furnish double or semi-double forms. Pyrus Aucuparia provides a totally distinct effect, and the several varieties of hybrid Crabs, such as John Downie, and Siberian Crab, provide a wealth of bloom and foliage followed by a crop of fruits of very fine colour, abundant in quantity and excellent for jellies. Of Pyrus communis I am not acquainted with any ornamental form. In the genus Prunus, the nurseryman and plant-breeder have provided us with a distinct ornamental section also, and their value over the fruiting varieties need not, I think, be laboured. These ornamental varieties have been evolved from the common types at the expense of great labour, thought and research, and that they serve their purpose in the sphere of ornamental trees and shrubs in a better manner than the strictly "fruiting" varieties could not well be denied. The person, however, who plants a Catillac Pear for its fine foliage and noble fruits, a Pott's Seedling Apple for foliage effect or any other variety of fruiting tree for columnar habit, striation or colour of bark, etc., should not be accused of want of good taste or lack of the aesthetic spirit, but be given credit for a particular appreciation of beauty in a special form. The reasons advanced against the public planting of fruiting varieties does not apply with equal force to private estates, but the underlying principles remain the same, and for that reason we seldom see them in ornamental plantations in England or France. It would be very interesting to hear from other readers of *The Gardeners' Chronicle* if this rule has been adhered to in other European countries or on the American continent. *B. H. M.* (*Milner, Son and White*).

SOCIETIES.

SOUTHPORT SHOW.

August 28, 29 and 30.—The clerk of the weather was extremely kind to the good people of Southport, and they thoroughly deserved his kind attentions. Rain fell during the eve of the show, and there were some light showers during the opening morning, but the afternoon of August 28 was pleasantly fine without being very warm, and rain fell at night. The second day was delightfully fine and rain fell again at night, so that dust was laid and everything was fresh for the final day. The attendance was wonderful and Southport broke all its previous records in regard to visitors and receipts.

The exhibition itself was the largest and the finest yet held at Southport, and the area it occupied was set out on page 157 of our issue of August 31. The show has gone from success to success, and has accomplished more in six years than any other function of similar character. This success is due, more than anything else, to the extreme courtesy and kindness of the Mayor, Aldermen, Councillors and Corporation officials and particularly to the untiring efforts of Mr. E. Wood, Mr. G. R. Crankshaw, Mr. C. Aveling and Mr. E. Clayton, with Mr. T. E. Wolstenholme, the Secretary, and Mr. W. Clark, the burly and genial Parks Superintendent, who is also the Show Superintendent. The way in which the whole of the show area, inside and out, was "washed and brushed up" each night was a fine example of the organisation of the show.

Competition was again good, and the avenues of artistic groups of plants, of hardy flower displays (Fig. 95) and of Roses, were wonderfully fine. Hardy Ferns constituted a good and interesting feature, while Dahlias and early-flowering Chrysanthemums produced vistas of splendid colour. The rock gardens did not impress us, but the non-competitive exhibits were magnificent, as a whole, and added greatly to the other attractions, while the big horticultural sundries section provided attractions for garden lovers of all grades.

We hope the Southport authorities will do nothing more to extend their show; it is quite big enough, and now they have achieved such success and such an important position in the horticultural world, they should concentrate on raising the quality and interest of the exhibits.

Two large and interesting features of this year's show were the exhibition of the British Gladiolus Society and the Sweet Pea Show arranged by Mr. A. C. Bartlett on behalf of the *Daily News*. Both exhibitions were admirable and are reported separately.

Rock and Water Gardens.

The rock gardens are now as much a feature of the Southport as of the Chelsea Show. On this occasion there were four competitors in the class for a rock garden or rock and water garden arranged on a space not exceeding 750 square feet. The Corporation Perpetual Challenge Cup and £50, offered as first prize, were won this year by Mr. E. T. **Rigg**, Kew Nurseries, Southport, who had a very pleasing design of well-placed rocks, lakelets and rivulets, a setting of closely-cropped grass and a restrained planting of dwarf Conifers, Heaths, Astilbe simplicifolia, dwarf Campanulas, Violas, neat little columnar Junipers, etc.

Second prize was won by Messrs. T. R. **Hayes and Sons**, Ambleside, whose arrangement of bold, weathered rocks was very imposing. The pools and waterfalls were as natural and picturesque as one expects from a "Hayes" design, while the Conifers, Campanulas, Astilbes, Heaths, Junipers and hardy Ferns were altogether pleasing. Third, Mr. R. **Thirkildsen**, Southport; fourth, Mr. P. **Gardner**, Addingham, whose design was broader than most.

Taken as a whole, however, the rock garden displays were not so attractive as on some previous occasions; we recognise that at this time of the year it is not possible to have rock gardens so gay as in the spring time, nevertheless, we are of opinion that if the rock garden exhibits are to continue to be an outstanding feature at Southport, the exhibitors must pay more attention to alpines and similar dwarf subjects—suitable, of course—that flower or otherwise give a bright effect at the end of August.

Groups.

The "group avenue" was once again a fine feature of the Southport Show, and for a combination of beauty of grace and colour the scene would be difficult to excel at a flower show.

The Challenge Trophy and first prize in the class for a group of miscellaneous plants in and out of bloom, arranged for effect on a space of 300 square feet, were won by Messrs. J. **Cypher and Sons**, Cheltenham—also last year's winners—with one of their delightful displays wherein lightly disposed arches with tall, bright Codiaeums, graceful Palms and Fuchsias, formed a splendid background for an artistic association of Codiaeums in great variety, Gesneras, Alocasias, Lilium speciosum, Humea elegans, Ixoras, Laelio-Cattleyas, Haemanthus carnea, Cypripediums, Francoa ramosa, Clerodendron fallax, and Nandina domestica, with Caladium argyrites and the variegated Saxifraga sarmentosa and Sedum Sieboldii var. variegata along the margins.

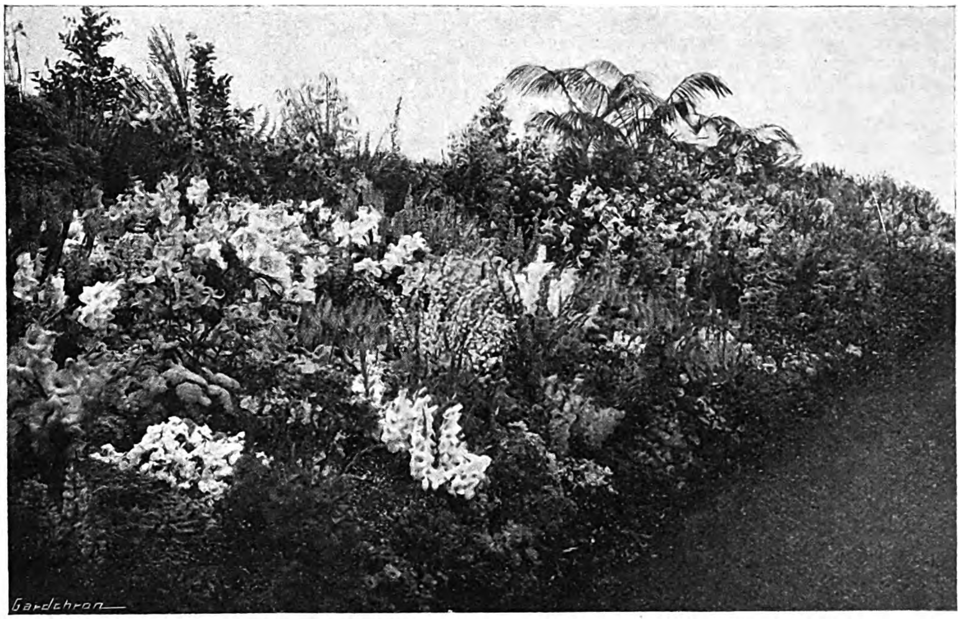

FIG. 95.—SOUTHPORT SHOW: THE HERBACEOUS AVENUE.

Sir **George H. Kenrick** (gr. Mr. J. V. Macdonald), Whetstone, Edgbaston, won second prize with a delightful exhibit that could not have been many points behind the Cheltenham group. Humea elegans, particularly well-grown Codiaeums, Bamboos, Ixoras, Francoa ramosa, wonderfully coloured Nandina domestica, the rare Dendrobium Goldei, Brassavola glauca in fine form, Cattleyas, Nerines, Oncidiums and Lilies were admirably arranged in this fine group. Mr. W. R. **Manning**, Dudley, third; and Mr. T. M. **Petch**, Bradford, fourth.

In the class for a group of foliage plants, arranged on a space of 300 square feet, there was a shuffling of positions, and Mr. W. R. **Manning** secured the Challenge Trophy and first prize with a very bold and well-arranged group. He had excellent Codiaeums, and these were very finely coloured and they no doubt turned the scales of justice in his favour. Mr. **Manning** also made good use of Palms, Ferns and Selaginellas, with Acalyphas, Alocasias, Ficus Parrcellii, various Caladiums, Dracaenas and Aralias. Messrs. **James Cypher and Sons** had to be content with second place, but they showed well, as also did Sir **George H. Kenrick**, who came third.

Hardy Flowers.

No class provided such a wealth of colour as the one for a collection of perennial and hardy herbaceous flowers arranged for effect on a ground space of 300 square feet. A handsome Challenge Trophy and £20 constituted the first prize, and this was won by Messrs. **Bees, Ltd.**, with a bold and gorgeous exhibit (Fig. 94). Hollyhocks and Helianthus made a fine background for huge sheaves of Lilium auratum, L. tigrinum, L. speciosum, L. Henryi, Agapanthus umbellatus var. albus, Crinum Powellii and C. P. var. alba, Gladioli of many varieties, Pyrethrums, Kniphofias, Scabious Lady Beaumont, Phloxes, Liatris, Campanulas and herbaceous Lobelias.

The **Gayborder Nurseries**, Melbourne, secured second place with a lower and more border-like display, in which Lavateras, Veronicas, Phygelius capensis, Lilium Henryi, Sidalceas and Acontum Napellus were outstanding subjects; third, the **Terra Nova School**, Birkdale.

For a collection of perennials, Gladioli, Liliums, etc., arranged on a ground space of 300 square feet, Messrs. **Maurice Prichard and Sons**, Christchurch, secured the premier award with a glorious exhibit of well-grown and well-arranged flowers. Kniphofias were particularly good, especially the varieties Royal Standard, Volante and Rufa; other fine subjects shown in large sheaves were Agapanthus umbellatus, Lilium auratum, L. Henryi, Crinum Powellii var. alba, Gladioli and Montbretias in variety, Poterium obtusum and Helianthus sparsifolius. Second, Messrs. **Harkness and Sons**, Leeming Bar, whose Gladioli were very good; third, The **Suffolk Seed Stores**, Woodbridge.

A new and popular feature was the class for a display of early-flowering, outdoor Chrysanthemums, arranged on a table space twenty feet by four feet. There were no fewer than eight competitors, who between them gave a fine demonstration of the value of these early-flowering varieties. The Dr. Barnes Trophy and first prize were won by Messrs. **Keith Luxford and Co.**, Sawbridgeworth, with a beautiful exhibit of clean, well-grown flowers of Mrs. Jack Pearson, Goldfinder, Bronze Early Buttercup, Shirley Pride, Elsenham White, September Glory, Crimson Circle, Harvester, Pink Delight, Carrie, Cranfordia and Gloria. Second, Mr. J. **Forsyth**, Putteridge; third, Mr. H. **Woolman**, Shirley, Birmingham; fourth, Mr. A. **Adshead**, Gatley.

Dahlias.

Dahlias in the big competitive class produced a splendid bank of colour. The schedule required a display of any varieties on a space twenty feet by four feet. The Aveling Trophy and first prize of £17 were won by Mr. H. Woolman, Shirley, Birmingham, with a handsome group wherein large-flowered Decorative sorts were H. B. May, Grace Darling, Mayflower, W. D. Cartwright and Ministre Baels; the new dwarf variety named Mrs. W. Clarke, a flame-shaded Single of Coltness Gem type, was also very attractive in this group. Second, Mr. E. Clegg, Dewsbury.

A superb lot of Dahlias secured the Crankshaw Trophy and first prize for Messrs. Burton and Sons, Elland, in the class for flowers arranged without artificial supports on a space forty feet by four feet. This firm displayed grand blooms of such large-flowered sorts as Mabel Lawrence, Berengaria, Ballet Girl, Jack Hobbs, Lord Lambourne, Exhibitor, Robert Treat, W. D. Cartwright (of immense size), Harry Strutt, Mrs. Warner and Silverado.

Messrs. Jarman and Co. came second, and had very fine blooms of Mabel Lawrence, Early Gem, Emma Groot, Mary Murray, Ballet Girl, Trentonian, E. S. Jackson, and Joyce Goddard (very bright). Third, Mr. H. Woolman.

Roses.

Mr. Thomas Robinson, Nottingham, annexed the Billington Trophy and first prize for the best display of Roses on a space twenty feet by four feet, with a very beautiful exhibit. Leading varieties represented by clean blooms in goodly numbers were Mabel Morse, Lady Inchiquin, Dame Edith Helen, Etoile d'Hollande, Madame Butterfly, Christine, Clarice Goodacre and Madame Herriot. Mr. C. Gregory, Chilwell, Nottingham, a very good second; Messrs. T. Smith and Son, Stranraer, third. This class was a most attractive one to the general public, and there were five competitors.

The premier award was won by Messrs. Benj. R. Cant and Sons, Colchester, in the southern class for a group of Roses, forty feet by four feet. This was a fine effort, and the clean flowers were displayed in baskets, pillars and other arrangements; second, Mr. J. Mattock, Headington. Messrs. D. Prior and Son, Colchester, led in the southern class for a display of Roses twenty feet by four feet.

There was a close tussle in the northern class for a display of Roses on a space forty feet by four feet, and here the Winterbottom Trophy and first prize of £20 were won by Messrs. S. McGredy and Son, Portadown, for a delightful exhibit of clean, bright flowers, largely displayed in baskets; a few of the leading varieties shown in good form were Portadown, Desmond Johnson, Arthur Cook, Mabel Morse and Shot Silk; second, Messrs. Bees, Ltd.

Messrs. Wheatcroft Brothers had the best three baskets of three dozen Roses, and were followed by Messrs. T. Smith and Son, Stranraer. Messrs. Adam and Craigmile, Aberdeen, beat the Donard Nursery Co., Newcastle, Co. Down, for twenty-four exhibition blooms of Roses.

Messrs. T. Smith and Son led for one basket of blooms of one variety, with Mrs. Henry Bowles; second, Mr. R. G. Ferguson, Dunfermline, with Earl Haig.

For three baskets of Roses (southern section), Mr. J. Mattock was the most successful exhibitor, showing Richard E. West, Shot Silk and Los Angeles in fine form. In the same section, Messrs. Frank Cant and Co., Colchester, led for two dozen exhibition blooms, with Mr. J. Mattock, second. The position of these firms was reversed in the class for one basket of fourteen blooms, and each showed the same variety—Dame Edith Helen.

In the county class for a display of Roses, five feet by four feet, the leading prize-winner was Mr. D. Mitchell, Bolton House, Blackpool, who had fine flowers of Captain Bald, Mrs. Foley Hobbs and J. G. Glassford; second, Mr. Robert Spaight.

Orchids, Begonias and Carnations.

J. B. Adamson, Esq. (gr. Mr. J. Hawes), Towneley Grove, Blackpool, secured the chief awards for Orchids, winning the Vestey Trophy for a group of these attractive plants; first prize for six Orchids, and also for three Orchids. It was regrettable that he had no competitors, especially remembering that there are two societies in the Manchester district devoting their attention to Orchids. Mr. Adamson's leading plants were Laelio-Cattleya Canberra var. Prince of Orange, Cattleya Hassallii var. alba, C. Hardyana var. June, C. Kienastiana var. alba, Cypripedium Rosettii, C. Greersonianum var. Gratrixianum, Miltonia Bleuana, Odontiodas and Odontoglossums.

Mr. T. L. Rushton, Garstang, Preston, secured the Blackmore and Langdon Trophy, *The Gardeners' Chronicle* Silver-gilt Medal and £7 10s.—the first prize—for a group of Begonias, and once again showed a very fine lot of plants of good varieties, and well arranged; second, Mr. W. Dodd, Formby; third, Mr. J. Irlam, Lytham, St. Annes. Mr. Rushton also won the premier award in the class for two specimen Begonias, while Mr. E. H. Henriques, Southport, and Mr. J. Walmsley, Ainsdale, were placed second and third, respectively.

The Engelmann Trophy for six plants of perpetual-flowering Carnations, was won by Mr. W. B. Feeny, Blundellsands (also last year's winner), who had capital specimens, and was followed, in a good competition, by Mr. C. H. Harpin, also of Blundellsands. For three vases of Carnations, however, Mr. Harpin turned the tables on Mr. Feeny, thereby winning the Rudolf Trophy. Mr. Charles Wall, Bath, secured the Trophy and first prize offered for a collection of perpetual-flowering Carnations, with a group of fine blooms of Laddie, Mrs. C. Ward, White Pearl, Glorious, Dixie, Spectrum and Saffron.

Some excellent plants were exhibited in the local classes, and we were attracted by the three fine specimen Ferns shown by Mr. W. V. Spencer, St. Helens; the three foliage plants from Cheadle Royal and the capital specimen Fuchsia, shown by Mr. A. Whitehead, Southport.

Hardy Ferns.

In their efforts to increase the culture and interest in hardy Ferns, the Southport authorities provided eleven classes for these plants and the competition therein was sufficiently good to warrant a continuation of the prizes offered.

The Abol Challenge Cup and £15, offered as first prize for a group of hardy Ferns filling a space of one hundred square feet, were again won by W. B. Cranfield, Esq., East Lodge, Enfield Chase, with a very pleasing arrangement of good examples of fine varieties associated with rocks and moss; the grouping was very attractive, and the little dell filled with Scolopendriums a distinct and pretty feature. Beautiful plants of fine forms of Polystichum angulare, Athyrium Filix-foemina var. clarissima and some especially good examples of the crispum section of Scolopendrium vulgare arrested attention in this collection from the foremost of present-day hardy Fern enthusiasts. Second, Mr. Joseph Lloyd, Southport; third, Messrs. Geo. Oliver and Sons, Melrose, the last-named showing small plants of choice forms.

Mr. Cranfield secured most of the premier awards in this section, winning first prizes for a dozen hardy British Ferns; six dwarf-growing British Ferns; six dissimilar Ferns in pots not exceeding nine inches in diameter, three Polypodiums, three Polystichums, three hardy British Ferns that originated as wild finds, and three dissimilar Ferns of garden origin. A few of Mr. Cranfield's finest plants were Polystichum aculeatum var. gracillinum, P. a. var. pulcherrimum, P. a. var. plumosum divisilobum, Lastrea Filix-mas var. cristata, L. F.-m. cristata var. The King, and Scolopendrium vulgare var. crispum speciosum.

Other prize-winners for hardy British Ferns were Messrs. G. Gibson and Co., Leeming Bar; Mr. W. F. Askew (who led for Aspleniums), Keswick; Mr. J. Lovelady, Haslingden; and the Rev. Canon H. Moore, Dundrum.

Violas and Pansies.

These popular flowers were exhibited in fine condition and the competition was keen throughout the numerous classes.

Names that appeared frequently on the principal prize cards were those of Messrs. Sanderson and Upton, Sheffield; Mr. J. Paul, Killicarn, Stirlingshire; Mr. J. Shepherd, Sheffield; Mr. R. Leslie, Whitehaven; Mr. H. Bairstow, Queensbury, Bradford; Mr. K. Johnstone, Bradford; Mr. H. Robertson, Kelty, Fife; Mr. J. Matthews, Pumpherston, Mid-Calder; Mr. F. J. Bell, Whitley Bay; Mr. H. Milner, Handsworth; and Mr. E. Clegg, Dewsbury.

Floral Designs.

These were not particularly good, except in the large class, but with the table decorations, they attracted a vast amount of attention and interest.

For a group of floral designs arranged on a space fifteen feet by five feet, Messrs. Bees, Ltd., led with a combination of beautiful, artistic and quaint designs; their cradle, parrot, telephone cover, cross, large basket, bowl and little donkey cart, were all fine examples of skilful craftsmanship; second, Messrs. Bakers, Wolverhampton; third, Miss Beatrice Skirrow, Southport; fourth, Mr. N. P. Millicent, Allerton; fifth, Mr. F. Drew, Walsall.

Mr. Moore, Wallasey, scored for three bouquets, with designs in Orchids and orange-coloured Roses; second, Mr. W. Hale, Great Crosby; third. Messrs. W. J. Garner and Son. Mr. Montague Stather, Cottingham, led for a hand bouquet, with bright-hued Orchids; second, Mr. C. Vickers. Mr. Stather was placed first for a basket of cut flowers, with a design in blue Agapanthuses and soft-hued, large-flowered Zinnias; second, Messrs. W. J. Garner and Son. Mr. Stather also led for a bowl of flowers, and had a pretty arrangement of Gerberas, pink Anthuriums and Bocconia sprays; second, Miss Newsham, with Liatris, Pyrethrums and Poterium sprays.

Mr. Stather was particularly successful in this section; he had the best bowl of Orchids, using Vanda coerulea, Odontiodas and Laelio-Cattleyas; second, Miss Nellie Gibson; third, Mr. J. Nixon. Mr. Stather had the best bowl of Carnations and the best bowl or basket of flowers suitable for a table decoration—a pleasing arrangement of Scabious. Mrs. Butchart, St. Swithin's Lane, London, won first prize for a bowl of Roses, with Messrs. W. J. Garner and Son, second. Mrs. Butchart was equally successful in the class for a vase of Roses. Mrs. J. Nixon led for a basket of Dahlias, a basket of Pansies and Violas, and a table centre of Pansies.

In the trade excluded class for a bowl of cut Roses, honour fell to Mr. L. Courtney Page, Haywards Heath, who had a fine display of Roselandia; second, the Cheadle Royal Hospital. Miss Newsham, however, beat Mr. Courtney Page for a table decoration of Roses, with a very dainty and pleasing design in Dainty Bess; Mr. Courtney Page used Emma Wright.

In the open class for a table decoration of flowers (Orchids excluded), Mr. Courtney Page led with a very fine arrangement of Roselandia Roses.

Special interest centred in the open class for a table decoration in Orchids, as here the first prize consisted of £7 10s. in cash and the Woodhead Trophy. Premier honours were well won by Miss Nellie Gibson, Stamford Hall Gardens, Loughborough, who has been a close runner-up on previous occasions, and received many well deserved congratulations upon her success this year. Miss Gibson associated Cattleya Hardyana, white Odontoglossums and golden Oncidiums as her central feature, with a base of coloured Odontoglossum sprays and Cypripediums; the corner-pieces were composed of soft mauve-purple Laelio-Cattleyas, and each had two short sprays of Oncidium varicosum, one pointing towards the centre-piece, and one towards a table corner Second, Messrs. W. J. Garner and Son, who had an effective arrangement of Odontoglossums, Cattleyas, Epidendrum vitellinum and mauve Dendrobiums.

There were numerous classes for table decorations, and in the one where bare, brown-stained tables had to be used, Messrs. W. J. Garner and Son won first prize with Francoa sprays and Gloriosa blooms. In an Orchid excluded class (on an oval table), Miss Newsham beat Mr. Stather with a bold design in Gladioli, Delphiniums and Kniphofias. In a Rose excluded class, Miss Newsham gained first prize with Gerberas and Mr. J. Nixon came second with Gloriosas and Orchids.

Decorated Fruit Table.

Out of four entries in a close competition in the class for a decorated table of choice fruits, the Marchioness of Tweeddale (gr. Mr. Alex. McBean), Gifford, East Lothian, won the Challenge Trophy and first prize of £30. The schedule requirements were twenty-four dishes of fruits in not fewer than nine distinct kinds. The Gifford display was a capital one, and included Muscat of Alexandria Grapes, clean and shapely; Alicante and Black Hamburgh Grapes; Marguerite Marillat and Souvenir du Congrès Pears, Ellison's Orange and Cox's Orange Pippin Apples (very fine); King George Melons, and fine Peaches, Nectarines, Plums and Figs. Apart from the value of the decorations—buff Carnations—the total number of points for the fruits was 143½

By-the-way, we suggest that when the judges have concluded their pointing, they and their steward should add up the possible points and set them against the actual points. In a crowded tent and with keenly interested people examining these tables, it is next to impossible for a busy pressman to total up the possible points for the sake of comparison with those awarded.

Second prize was won by the Duke of Newcastle (gr. Mr. S. Barker), Clumber, who showed very fine Peaches, excellent Apples and Grapes, Pears, Nectarines, Figs and Melons; his points for fruits were 140; third, Lord Belper (gr. Mr. J. McCartney), Kingston Hall, Derby, with 134½ points for fruits; fourth, Mr. A. Mason, Newby Hall Gardens, Ripon, with 125 points for fruits.

Two very attractive exhibits were staged in the class for a decorated table of British and/or foreign fruits; a space of ten feet by four feet was provided, and fourteen dishes or other receptacles had to be filled. The Aveling Trophy and premier award was won by Mr. M. Wright, Southport, with a central stand of Pineapples, elegant baskets of black and white Grapes, Melons in variety, Peaches, Nectarines, Nuts, Pears and Oranges. The whole was decorated with pink Carnations and white Heather. Second, Mr. G. Hallam, Sandon Road, Birkdale.

Among the several classes provided for Grapes, the chief was the one for twelve bunches in four or more varieties, but not more than four bunches of any one variety. Here the premier award is the Rhodes Trophy valued at £30, together with £25 in cash. Having won a previous trophy outright in 1928, the Earl of Strathmore (gr. Mr. D. McInnes), Glamis Castle, Forfarshire, led again this year, and so laid the foundation of success for winning the new Wilkinson Trophy, which has to be won three times to become the property of a competitor.

The Glamis collection of Grapes consisted of shapely, good-sized, nicely finished clusters of Muscat of Alexandria (4), Muscat Hamburgh (4), Gros Maroc (2), and one bunch each of Black Hamburgh and Chassilas Napoleon. The points awarded were 87 out of a possible 121. Lord Belper came second, with 81 out of a possible 122 points; Captain W. H. France-Hayhurst (gr. Mr. A. H. Hall), Bostock Hall, Middlewich, third, with 78½ points out of a possible 119; and the Duke of Newcastle, Clumber, fourth, with 72½ points out of a maximum of 120.

Dyson Perrins, Esq. (gr. Mr. G. F. Anderson), Davenham, Malvern, won first prize for four bunches of Grapes in not fewer than two varieties, and he was followed by Mr. W. Parker, Mansfield, and Mr. W. Izzard, Newark, in order as named. The Duke of Newcastle led for a pair of bunches of white Grapes, with Buckland Sweetwater; second, T. Henshaw, Esq., Roby; third, H. Rigby, Esq., Blackpool.

Colonel Hughes, Shardley Hall, St. Helens, had the best single bunch of Black Hamburgh Grapes. The Duke of Newcastle scored firsts for two bunches of Black Hamburgh and for two bunches of Madresfield Court. Mr. W. Parker led for two bunches of black Muscat Grapes, the Duke of Newcastle coming second. Captain France-Hayhurst received first prize for a pair of bunches of Alicante, while T. G. Moore, Esq. (gr. Mr. W. H. Friend), Castleton, Isle of Man, led for two bunches of "any other" black variety, and the Earl of Strathmore beat Dyson Perring, Esq., in the class for two bunches of white Muscat Grapes.

Vegetables.

Vegetables were shown extensively and well. The collections were arranged in the centre of one large tent, while the sides were filled with a vast number of exhibits in the numerous single dish classes.

Special interest centred this year in the new class for a display of vegetables arranged to face all ways on an oval table fifteen feet by ten feet. Here, as at Bakewell, the competition was confined to Lord Leconfield (gr. Mr. F. Streeter), Petworth, Sussex, and Dr. Roy (gr. Mr. Allan Falconer), Cheadle Royal Mental Hospital, Cheadle, but whereas Cheadle Royal won handsomely at Bakewell, Petworth left nothing to chance at Southport, and so won the Peter Walker Challenge Trophy and £20, offered as first prize.

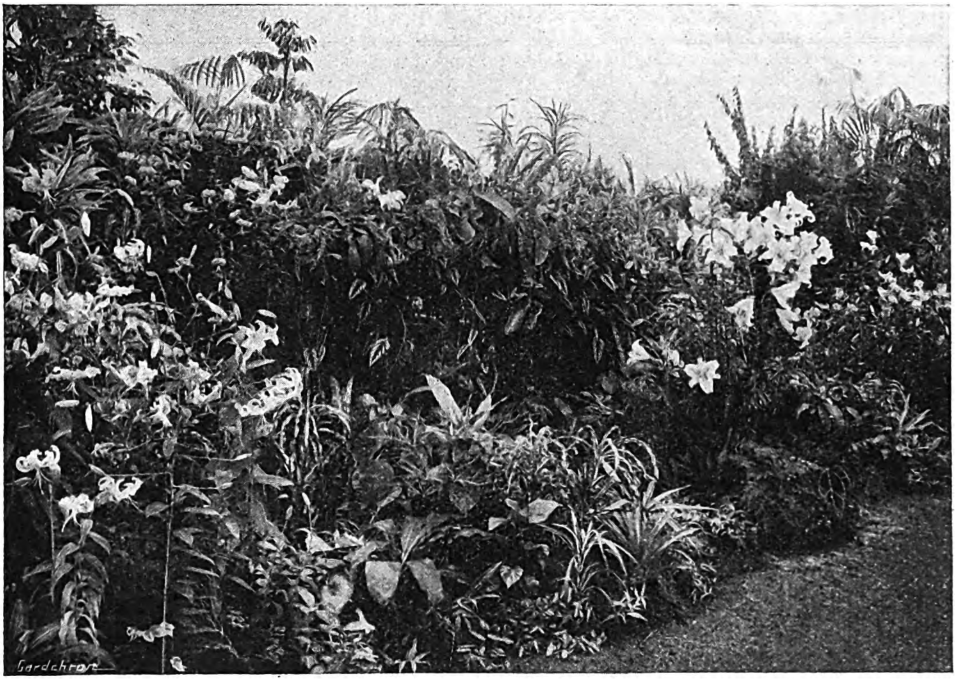

FIG. 96.—SOUTHPORT SHOW: T. G. MOORE, ESQ.'S GROUP OF INDOOR PLANTS.

Lord Leconfield's display was a particularly bright one, and Mr. Streeter made good use of coloured-podded Peas and Beans, Capsicums and Chilies, Aubergines and Gourds, but also showed high-class examples of Onions, Celery, Leeks, Parsnips, Cauliflowers, Carrots, Tomatos, and Cucumbers. This was a very fine and very attractive exhibit, but the same may be stated of the display from Cheadle Royal, for although Mr. Falconer was beaten, he gave few points away; both competitors are to be congratulated upon their splendid demonstrations of high culture and skilful exhibition of vegetables.

When Messrs. Jones and Son, of Ammanford, set out to win a prize for vegetables they rarely fail in their aim, and so on this occasion they secured the open championship by winning the Larking Trophy and £10 offered for the best collection of twelve distinct kinds of vegetables. The Ammanford produce is always well nigh perfect in size, form and colour. At Southport, it consisted of Onions, Leeks of superb quality, Parsnips, Tomatos, wonderful Runner Beans, The Bishop Potatos, Celery, Cucumbers, Cauliflowers, Carrots and Peas. Second, Mr. W. Robinson, Foxton, near Garstang; third, Colonel G. Pilkington, St. Helens; fourth, T. G. Moore, Esq., Castleton, Isle of Man.

Mr. W. Robinson is invariably a successful competitor and this year he won premier awards in two classes for collections of vegetables. Other prize-winners in specially provided classes for collections were Mr. T. M. Jones, Llandilo (Carters'); Mr. J. Rimmer, Codishead (Clucas'); Messrs. Jones and Son, Ammanford (Dickson and Robinson's); and Mr. John Evans, Llandilo (Suttons'), Tadworth; Lord Riddell and Mr. Weaver, Mold, were other successful exhibitors in vegetable classes.

Awards of Merit

Carnation Startler.—A scarlet, sweetly-scented variety. From Messrs. C. Engelmann, Ltd.

Dahlia Dr. Helmet Spath.—From Messrs. Fairbairn and Sons.

Chrysanthemum Robert McAlpine.—A large and elegant early-flowering variety; red with rose shading. From Mr. A. McAlpine.

Venidium fastuosum. — A large-flowered, strong-growing yellow, South African annual (see coloured plate in our issue of February 2, 1929). From Messrs. Sutton and Sons.

Non-Competitive Exhibits.

These were very attractive and some were of particular interest. The Hon. Vicary Gibbs (gr. Mr. E. Beckett), Aldenham House, Elstree, excelled all previous efforts, wonderful as these have been, in the display of superbly-grown vegetables (Fig. 85). Mr. L. R. Russell's economic plants; Mr. Amos Perry's aquatic and bog plants (Fig. 86); Messrs. Sutton and Sons' Gloxinias; Mr. G. Smith's rare plants, from Newry; fruit trees in pots from the King's Acre Nurseries; Peaches and Nectarines from Messrs. T. Rivers and Son; stove and greenhouse plants from Messrs. J. Peed and Son and Mr. T. G. Moore—who brought a large group (Fig. 96) of interesting subjects (including Nepenthes and Orchids) from the Isle of Man; Messrs. Dobbie and Co.'s Dahlias; Messrs. Alex. Dickson and Sons' Roses; Messrs. Dickson and Robinson's Dahlias and Stocks; the Carnations from Messrs. Allwood

Brothers and Messrs. C. Engelmann, Ltd.; the Sweet Peas from Messrs. Robert Bolton and Sons; and Messrs. Bees formal garden; were a few of the most outstanding exhibits. Awards were made as follow :—

Cups and Trophies.

"*The People*" *Challenge Trophy,* for the best non-competitive exhibit in the show.—To the Hon. Vicary Gibbs (gr. Mr. E. Beckett), Elstree, for a display of vegetables; with the congratulations of the judges.

Scenic Railway Trophy, for the best display of pot-grown fruit trees.—To the King's Acre Nurseries, Ltd.

Boothroyd Trophy, for the most meritorious non-competitive formal garden.—To Messrs. Bees, Ltd., Liverpool.

Rushton Challenge Trophy, for Orchids.—To Messrs. Charlesworth and Co., Haywards Heath.

Medals.

Large Gold.—To Messrs. Allwood Brothers, for Carnations and Dianthi; Messrs. Blackmore and Langdon, for Begonias and Delphiniums; Messrs. Bees, Ltd., for a formal garden; Messrs. R. H. Bath, Ltd., Wisbech, for Gladioli; Messrs. R. Bolton and Son, for Sweet Peas; Messrs. Dickson and Robinson, for Dahlias, etc.; Messrs. Alex. Dickson and Sons, Ltd., for Roses and Sweet Peas; Messrs. Dobbie and Co., Ltd., for Roses, Dahlias and Sweet Peas; The Donard Nursery Co. (Co. Down) for shrubs, herbaceous and bulbous flowers; Messrs. C. Engelmann, Ltd., for Carnations; The Hon. Vicary Gibbs, Aldenham, Elstree, for vegetables; Messrs. Hodsons, Ltd., for a rock and water garden; Messrs. Kent and Brydon, Ltd., for a formal garden; The King's Acre Nurseries, Ltd., for fruit trees in pots; The Lancashire County Council, Education Dept., Preston, for a horticultural educational exhibit; Mr. T. Smith (Newry), for rare trees and shrubs and hardy plants; Messrs. Sutton and Sons, for Gloxinias and Sweet Peas; Messrs. John Peed and Son, for stove and greenhouse plants; Mr. Amos Perry, for aquatics and Water Lilies (with special congratulations of the judges); Messrs. T. Rivers and Son, Ltd., for fruit trees in pots; Messrs. L. R. Russell, Ltd, for economic and medicinal plants, Water Lilies and other aquatics; Mr. K. Therkildsen, for a formal garden; and to Messrs. W. J. Unwin, Ltd., for Gladioli.

Gold Medals.—To Messrs. Backhouse Nurseries (York), Ltd., for a miniature rock garden; Messrs. Barr and Sons, for new hybrid Montbretias; Messrs. Charlesworth and Co., Ltd., for Orchids; Messrs. J. L. Clucas, Ltd., for vegetables; Miss Evelyn M. Cowell (Sutton Coldfield), for a formal garden; The Churchtown Council School, Southport, for fruits, flowers and vegetables grown by boys of the School; Messrs. Daniels Brothers, Ltd., for Gladioli and Montbretias; Mr. John Evans, for Orchids; Messrs. Fairbairn and Sons, for Phloxes; Messrs. John Forbes (Hawick), Ltd., for Phloxes and Pentstemons; the Florists' Telegraph Delivery Association, for floral art; Messrs. J. Kelway and Sons, for Gladioli; Messrs. A. J. Keeling and Sons, for Orchids; Mr. Robert Lawrie, Carnwath, for Begonias; Mr. James MacDonald, for a grass garden; Messrs. Maxwell and Beale, for alpines and Heaths; T. G. Moore, Esq., Castletown, Isle of Man, for stove and greenhouse plants; Mr. H. Prins, for Dahlias, Gladioli and Liliums; Messrs. W. H. Simpson and Sons, for Gladioli and Antirrhinums; Messrs. Toogood and Sons, Ltd., for a mixed floral exhibit; Mr. C. Vickers, for floral designs; and to Messrs. Hewitt and Co., Ltd., for Delphiniums and Roses.

Silver-Gilt Medals.—To Mr. E. J. Bayley, for Gladioli, Montbretias and annuals; Messrs. Bakers, for hardy plants and flowers; Messrs. Matthew Campbell and Son, for border Carnations; Messrs. Ben. R. Cant and Son, Ltd., for Roses; Messrs. D. and W. Croll, Ltd., for Potatos; Messrs. Dickson's Nurseries, Ltd., for Roses and floral designs; and one for ornamental shrubs; Mr. H. N. Ellison, for exotic Ferns; Messrs. G. Gibson and Co, for alpine plants; Mr. P. Gardner, for a Heath garden; Mr. F. E. Green, for topiary; Mr. W. F. Gullick, for Scabious; Messrs. Isaac House and Son, for Scabious; Mr. Robert Hayes (Grassmere), for shrubs, Heaths and alpine plants; Mr. P. Johnson (Southport), for alpine plants; the King's Acre Nurseries, Ltd., for Roses; Mr. John Klinkert, for topiary; Messrs. Laxton Brothers, for Roses; Mr. Robert Nanson, for Roses; Messrs. Geo. Mair and Sons, for large-flowered Gladioli; Messrs. Middlehursts, Ltd., for vegetables, grasses and Gladioli; Messrs. Rich and Cooling, Ltd., for hardy flowers; Messrs. S. Smith and Sons, for Cacti and Succulents; Messrs. Velthuys and Co., Ltd., for Gladioli; Mr. W. H. Walters, for rare hardy plants; Mr. W. Wells, junr., for hardy flowers; Messrs. Wm. Wood and Sons, Ltd., for hardy plants; Mr. B. Waterhouse (Crewe), for Dahlias and Gladioli; and to Messrs. Wheatcroft Brothers, for Roses.

Silver Medals.—To Messrs. C. H. Bloom and Sons, for hardy perennials; Messrs. Bowell and Skarratt, for alpine and aquatic plants; Mr. H. Clarke, for Larkspurs, etc.; Garden Supplies (1929), Ltd., for alpine and herbaceous plants; Mr. John Golding (Fordham), for Scabious; Mr. Charles Wm. Holt, for alpines and British Ferns; Mr. T. R. Hayes, for alpine plants; Mr. John Jones (Wem), for Violas and Pansies; Messrs. Jones Brothers, for hardy flowers; the King's Acre Nurseries, Ltd., for Dahlias and Chrysanthemums; the Kippen Vinery Co., for Grapes; Messrs. Leightons (Glasgow), for herbaceous and alpine plants; Mr. O. Milne-Redhead, for dwarf shrubs and plants; Mr. J. F. Rashley, for a small rock garden; Mr. F. Rich, for Phloxes, etc.; Mr. Edmund J. Rigg, for alpine plants and dwarf shrubs; Messrs. Sutton Brothers, for Orchids; Mr. Stephen Sims, for a miniature rock garden; Mr. Geo. G. Whitelegg, for hardy flowers; Mr. Geo. E. P. Wood, for a small rock garden; and to Messrs. W. Brown and Son, for hardy shrubs and climbers.

Cultural Commendation.—To Messrs. Clibrans for fruits of Apples A. W. Barnes, M. A. Barnes and Lord Lambourne.

"DAILY NEWS" SWEET PEA SHOW.

Sweet Peas have become a very important feature of the Southport Flower Show. Last year the National Sweet Pea Society, in association with the *Daily News*, and on the invitation of the Flower Show Committee, held a very successful Provincial Show at Southport. This year the Society held its Provincial Show at Norwich, so the *Daily News*, to continue its association with Sweet Peas and Southport, provided an excellent schedule of prizes which attracted an exceptionally large number of entries from almost all parts of the country and brought together a vast collection of exceedingly fine sprays of bloom which made one of the largest and very best competitive Sweet Pea shows that have ever been held. As would be expected in the circumstances, there were no entry fees, and the schedule included classes for all grades of growers, from the veritable novice to the skilled and seasoned expert amateur Sweet Pea grower. With one exception the competition in all the classes was admirable. At the onset the *Daily News* enlisted the assistance of Mr. A. C. Bartlett, the Secretary of the National Sweet Pea Society, who was responsible for the comprehensive schedule and admirable arrangements of the show. Recognising that such a show as that which the *Daily News* was holding would further general interest in their special flower to a considerable extent, the Committee of the N.S.P.S. willingly lent their show vases for the occasion, so that there was the desired uniformity of staging. The *Daily News* and all concerned are to be congratulated on the success of the show.

Amateurs' Classes.

The *Daily News* Championship class, which required twelve vases of distinct varieties, was immensely successful from every point of view. There were no fewer than twenty-eight entries, and as the quality of the blooms was consistently high, the long array of exhibition blooms presented a spectacle which gladdened the eyes of the many Sweet Pea enthusiasts who inspected them with keen appreciation. The valuable Silver Trophy and cash prize of £20 were won by Mr. J. G. Robeson, Banbury, who is well-known as a very enthusiastic and successful amateur exhibitor of Sweet Peas who grows his plants unaided. It was a collection of superb Sweet Peas of high quality, well deserving of the valuable prize and the occasion. The varieties were Mrs. A. Searles, which was awarded the Gold and Enamel Medal as being the best vase in the show, Royal Mauve, Royal Pink, Valletia, Model, Magnet, Powerscourt, Youth, What Joy, Mammoth, Pinkie and Olympia. Samuel Wallrock, Esq. (gr. Mr. W. H. Holloway), The Manor House, Stanmore, Middlesex, was a very good second in this strong class, and his splendid exhibit could not have been many points behind the winners. Here again, the exhibit was characterised by very high and even quality; it included in a magnificent vase of Powerscourt, the second best vase in the whole show, and was awarded the Gold Medal. Model, Mrs. A. Searles, Youth, Gold Crest and Susan were of great excellence. Miss K. Allington Hughes, Wrexham, was third; Mr. John Haycocks, Wrexham, fourth; and Mr. John A. Grigor fifth in this stupendous class, where several other exhibits which ordinarily would have won prizes went unrewarded.

The seven colour classes continued the high quality of the Championship Trophy class, and here Mr. Samuel Wallrock was particularly successful, for he won five of the first prizes with the following varieties :—Magnet, pink; What Joy, white or cream; Mrs. A. Searles, cerise or crimson; Gold Crest, orange or scarlet; and Youth, Picotee-edged. Mr. G. H. Brookshaw, Hough, near Crewe, was first in the class for a vase of any blue, mauve, lavender or purple variety, with Powerscourt, while in the class for a vase of any colour not mentioned above, Mr. H. Stubbs, Knutsford, was first with Corona, which was also shown in good form by another exhibitor. Brilliant Rose and The Sultan were other noteworthy varieties.

The English county district classes were all well contested. As was to be expected so late in the season, there were most entries in the northern counties class, where Mr. H. Stubbs was first with excellent vases of Magnet, Model, Youth, Purple Monarch, Powerscourt and Mrs. A. Searles. Mr. G. H. Brookshaw was second, and Mr. J. Cyril Lockwood, Ranmoor, Sheffield, was a good third. There were twelve entries in the midland counties class and here Mr. R. Challinor, Balterley, Crewe, was first with an admirable collection of which the best vases were Lilac Queen, Sybil Henshaw, Powerscourt and Youth. Mr. H. E. Welch, Belper, Derby, was second, and Mr. George Kent third. Of the nine entries in the southern and western class, the best was by Samuel Wallrock, Esq., who again set up a noteworthy exhibit. His very best varieties were Model, Charming, Huntsman and Gold Crest. Mr. F. Churchward, Kingskerswill, South Devon, was a worthy second, and Mr. F. H. Hannah, Bushey Park, Hertfordshire, third.

As last year, when the National Sweet Pea Society held a Provincial Show at Southport, the Scottish entries were disappointing in numbers, despite the fact that extra classes were arranged. On the present occasion there were only five entries in each of the three classes. Mr. John A. Grigor was first in the class for six varieties and also for three varieties. His best sorts were Wild Rose, Powerscourt, Avalanche, Grenadier, Lilac Queen, Pinkie, Miss California and Purple Monarch. Mr. George Ballingall, Dumbarton, who was second in each instance, was first in the class for a vase of three distinct varieties, which he arranged very effectively.

The Irish entry did not materialise. In the Welsh class, Mr. John Haycocks was first with admirable vases of Treasure, Mrs. A. Searles, Valetta, Sunkist, What Joy and Magnet.

The Novices' Section was immensely popular, and the five classes averaged twenty-eight entries in each. Mr. Tom Jones, junr., Ruabon, won first prizes for six vases and for three vases, with especially good blooms, and was also first with a colour scheme in three varieties. Mr. F. Brown, Blackburn, was the most successful exhibitor of one distinct variety. The novel class for the spike bearing most flowers drew forty entries, and the first prize was won by Mr. Samuel Wallrock, with a slightly fasciated spike of Mrs. A. Searles bearing ten good blooms.

Open Classes.

It was rather late in the year to expect large competition in the novelty classes, although the quality was very gratifying. Messrs. Robert Bolton and Son were first in both classes. Their three novelties included Stellate, a beautiful cerise flower flushed with orange, and unnamed pink and cerise seedlings. The single variety was Fire Glow, a fine, rich cerise, flushed with oriental-red on a white base. Mr. J. Stevenson was second in the class for three varieties with very good seedlings.

The decorative displays of Sweet Peas arranged on tables measuring twelve feet by six feet were a very delightful feature of the show. Messrs. A. Leigh and Son won the Silver Challenge Trophy and first cash prize with a superb display in which they used splendidly-grown flowers of such varieties as Mammoth, Colorado, Mrs. A. Searles, Magnet, Venus, Model and Gold Crest. Messrs. W. Scott and Sons, who were second, had a graceful table, and used Grenadier, Susan, Picture, Magnet, Sybil Henshaw and other varieties to good effect. Messrs. Herd Brothers were a good third; Mr. A. Johnson, fourth; Mr. R. Wright, fifth, and Messrs. J. Cook and Sons, sixth.

The *Daily News* open decorative classes were also very successful. The best of the many designs of Sweet Peas was the golden gates ajar, made by Mr. R. Dewhurst. Mr. Montague Stather was second, and Mr. J. Pilkington third. Mr. A. Johnson had the best lady's spray, and Mr. Walter Martineau was first with a gentleman's buttonhole of Sweet Peas. The numerous brides' bouquets were especially beautiful. Millicent's Florists had the best, and Mr. M. Stather the second best.

In the Southport amateurs' classes there were many vases of good Sweet Peas. Mr. T. H. Russell, Ainsdale, was first in the class for six vases, while Miss Isa Schofield, Southport, was first in the class for four vases.

The only non-competitive exhibit of Sweet Peas was one of the superb displays which are expected from Messrs. Robert Bolton and Son. This was composed of splendid blooms of a great many of the best varieties and well deserving of the special Gold Medal which was awarded.

BRITISH GLADIOLUS.

August 28, 29 and 30.—This special flower Society held an "International Show" on these dates, in conjunction with the great Southport Flower Show. The allotted space was well filled with Gladioli, and the portion set aside for the large displays by the trade made a magnificent avenue of brilliant flowers. While this bold and striking effect was, of necessity, absent in the classes for smaller exhibits, these contained many admirable varieties. The competition among amateurs and especially in the many single spike classes was very good. Many novelties received award, but as most of them were placed among the general exhibits we fear that the visitors generally often failed to appreciate their charm and beauty at their full value. The enthusiastic and energetic Hon. Secretary very kindly furnished us with a full list of the awards.

Silver-Gilt Medals.

Annie Gregg.—A large-flowered variety; the light cream ground is overlaid with blush-pink, and the margins are flecked with pink. There is a yellow throat with crimson median lines. Shown by Mr. S. H. Gregg.

Ajax.—This very attractive, slender-spiked, scarlet, Primulinus variety was also given an Award of Merit. Shown by Mr. J. L. Gibson.

Silver Medals.

Gertrude Amos.—A large-flowered variety with salmon-pink ground, heavily flecked with deep pink on the edges. There is a small, crimson blotch and ruffled petals. Also granted an Award of Merit. Shown by Messrs. W. J. Unwin, Ltd.

Mrs. G. C. Taylor.—Primulinus. A glowing salmon-pink Primulinus variety, which has crimson-lake lines on the pale orange throat. Shown by Mr. J. L. Gibson.

Bronze Medals.

Christine Prior.—A large-flowered variety in which the salmon ground is heavily flaked with slaty-blue. The throat is spotted and the petals slightly waved. A tall, striking variety. Also given an Award of Merit. Shown by Messrs. Kelway and Son.

Edgar Ingham.—A salmon-pink Primulinus grandiflorus variety with a clear yellow blotch and broad, white median lines. Slender spike. Also given an Award of Merit. Shown by Messrs. Kelway and Son.

Awards of Merit.

Dainty.—A salmon-pink Primulinus grandiflorus, with deeper colour at the margins; a lemon blotch and scarlet throat. Shown by Messrs. R. H. Bath, Ltd.

Gloriana.—A beautiful, large-flowered variety which has golden-salmon colouring with a yellow throat. Shown by Messrs. R. H. Bath, Ltd. and by Mr. J. L. Gibson.

Mrs. W. J. Unwin.—A large-flowered, pale pink variety with deeper pink at the edges, and white median lines; the white throat is feathered crimson. Shown by Messrs. K. Velthuys and Co.

Carminea.—A large-flowered Gandavensis variety of deep ruby-crimson colouring, with a white blotch. A handsome flower. Shown by Messrs. G. Mair and Sons.

David Prior.—A magnificent, large-flowered, orange-scarlet variety, with slight markings on the yellow throat. The large, ruffled flowers are of splendid texture. Shown by Messrs. G. Mair and Sons.

Dark Lantern.—A rich, ruby-crimson, large-flowered variety with cream feathering in the throat. Shown by Messrs. Kelway and Son.

Senorita.—A clear orange-yellow, with carmine tongue and pencilling; large, widely open florets. Of uncommon appearance, Shown by Mr. H. Prins and Mr. A. E. Amos.

Alice Amos.—This large-flowered variety is creamy-white at first and opens to almost pure white with a creamy tint in the throat. Shown by Mr. A. E. Amos.

Open Classes.

The only exhibit on a table space twenty-five feet long was by Messrs. K. Velthuys and Co., Ltd., and they most ably demonstrated the great decorative value of the Gladiolus when boldly arranged in suitable receptacles and with appropriate foliage. The class for the Nurserymen's Championship brought better competition, and here the first prize was won by Messrs. W. J. Unwin, Ltd., who filled the thirty-feet run of tabling with splendid spikes arranged with considerable skill and taste. The large-flowered sorts were especially good, and these included Anna Ebenus, Rose Ash, Thomas Edison, Bleriot, Dr. F. E. Bennett and Mrs. Dr. Hauff. The most prominent of the many graceful Primulinus varieties were Souvenir, L'Egaillon, Orange Queen and Xanthia. Messrs. W. J. Unwin, Ltd., were also awarded the first prize for a beautiful exhibit of all sections of Primulinus hybrids. Mr. H. Prins was second, and Messrs. W. Artindale and Son were third, in the large class, both showing very good collections.

The first prize for twenty-four large-flowered varieties, introduced during the past three years or not yet in commerce, was won by Messrs. G. Mair and Sons with magnificent spikes which bore an exceptionally large number of fully open flowers. The varieties included Lochnagar, Faust, David Prior, Quality, Rachel, Golden Sheen and The Fawn; Messrs. Kelway and Son were second. In the similar class for Primulinus varieties, the Championship Cup was won by Messrs. R. H. Bath, Ltd., with a graceful exhibit of such varieties as Salmon Queen, Beauty of Cambridge and Aurora; Messrs. W. J. Unwin, Ltd., were second, and Messrs. Kelway and Son third. Mr. W. Yandell was awarded the first prize for a good exhibit of twenty-four spikes of any of the two sections of Gladioli, and Mr. H. Prins had the best exhibit of twelve florist or commercial varieties.
